We do not feel ourselves called upon to pronounce any opinion upon strictures originating in the pages of another journal, and must therefore decline to enter into any controversy founded upon the supposed injustice done to Dr. EDMONDS by the exclusion of his statement from the Medical periodical in question; but the whole history is important in a medico-legal point of view, and we therefore refer to the case as one full of instruction and of warning, and we shall pass over as lightly as possible all personal and private matters, confining our review of the facts to such striking features as seem to possess some special points of scientific or professional interest.

Dr. MILLETT is a medical gentleman practising in Cornwall, and on the 31st of December, 1863, his brother, Mr. JACOB MILLETT, who was residing in the same house with him, died after a few hours' illness. The deceased was fifty years old, almost blind, and partially crippled from malformation of bones, but he was nevertheless healthy in other respects, and on the day

immediately preceding his death he had walked out as usual, had eaten his breakfast, afterwards a hearty dinner, and it was after the latter meal that he was seized with the illness which proved fatal. He had executed a will, leaving some little property of which he was possessed to his brother, Dr. MILLETT, who had taken great care of him, and indeed supported him. Except as regards the shortness of the illness, there was really nothing very extraordinary in the death of this invalid and crippled gentleman; but Dr. MILLETT very properly communicated with the Coroner of the district, and requested him to hold an inquest. Here, however, commenced the series of misunderstandings and misadventures which terminated so unfortunately. The Coroner's jury, after hearing the evidence of Dr. MILLETT and a female servant, but without asking for any post-mortem examination, returned a verdict of "Natural Death."

In this part of the proceeding, also, there was nothing extraordinary, and however absurd it may seem to Medical men that a legal Coroner and an ordinary jury can determine, in the absence of any visible cause of death or any post-mortem inspection, whether a given death is natural or not, yet such verdicts are returned every day, and the public are quite satisfied with their validity. For our own parts, we may observe that, speaking from a Medical point of view, we regard a Coroner's Inquest as a mere farce, unless a careful examination of the interior of the body of the deceased person forms part of the inquiry, except in those cases where the external appearances or other obvious circumstances sufficiently explain the cause of death. Where there is anything like suspicion, or even an apprehension that suspicion may arise, as to a possibility of the death having been caused by poison, we consider a post-mortem examination to be an indispensable adjunct to the Coroner's official investigation. But these opinions are probably not shared by the public, and we offer them only in a parenthetical form.

But now Dr. EDMONDS comes upon the scene. He is Dr. MILLETT's brother-in-law, having married that gentleman's sister; and during his residence abroad it seems that much family disagreement had arisen; and when Dr. and Mrs. EDMONDS returned to this country, this disagreement continued to exist. While living in the vicinity of London, Dr. and Mrs. EDMONDS were informed of the death of JACOB MILLETT, but it does not appear that either of them attended the funeral. From some correspondence which ensued between different members of the family, it would appear that Dr. EDMONDS was induced to go into Cornwall after the funeral, with a view, as he declares, to obtain a post-mortem examination of the body of JACOB MILLETT. We must state, in justice to Dr. EDMONDS, that in merely attempting to carry out this view, we cannot consider that he was blameable; but in some way or other, either from his own imprudence or his excess of zeal, or his ignorance of legal formalities, or, as was alleged, from

malice against Dr. MILLETT, he was induced or dragged into becoming the persecutor of that gentleman on a charge of poisoning his deceased brother. The post-mortem examination, however, was obtained, the exhumation of the body having been effected by an order from the Secretary of State, and the autopsy was confided to two local practitioners, who performed that duty in the presence of Dr. EDMONDS.

Here, it seems to us, arose another false step in the progress of this unfortunate drama. The post-mortem examination revealed nothing in the state of the body to justify in the remotest degree the suspicion of poisoning, but in the brain there was found a quantity of effused fluid, amounting, as one of the Medical witnesses declared, to a pint, and accounting, as we believe, most satisfactorily, for the death of the deceased gentleman. Still we do not blame the Medical witnesses for removing the viscera, which they did with a view to their being analytically examined by chemical and physiological tests, and we find that these parts were sent up to Dr. ALFRED TAYLOR for that purpose. But surely, as there was positive evidence of disease of the brain, and, at the very utmost, only the faintest negative evidence of poisoning, it was most cruel and unnecessary to incarcerate Dr. MILLETT upon the barest suspicion, while Dr. TAYLOR was completing his analysis. We do not wish to cast unnecessary blame upon the two Medical gentlemen who conducted the post-mortem examination, and who admitted, in their evidence, that they were practically unacquainted with the morbid appearances caused by poisoning; but still we cannot help thinking that, if they had represented to the magistrates the entire absence of any physical signs of poisoning, and had at the same time stated that the effusion in the brain was at least sufficient to account for death, Dr. MILLETT would never have been incarcerated at all, but would have been allowed to go out upon bail until Dr. TAYLOR's analysis had been made. The result of that analysis was, that no poison whatever was contained in the viscera of the deceased, and as soon as this report was received Dr. MILLETT was of course discharged.

But the two Medical witnesses who performed the post-mortem examination, and also Dr. EDMONDS, persisted in declining to offer any opinion as to the death having ensued from natural causes, and by implication, if not by direct assertion, they attributed the event to the agency of poison, and it was upon this evidence that the magistrates ordered the incarceration of Dr. MILLETT. We are willing to believe that their opinions, however erroneous, were sincere, but still the consequences were so dreadful to Dr. MILLETT that we cannot wonder at his immediately bringing an action against Dr. EDMONDS, or at his obtaining a verdict.

We have stated that this case is one possessing considerable scientific and practical interest. In the first place we think that it is prudent, in case of the sudden and dangerous illness of a near relative of a medical man, for another practitioner to be called in, if it is

practicable; and in the event of death, that a post-mortem examination should be made if a Coroner's inquest is deemed necessary. Next, we think that when medical witnesses are selected to make post-mortem examinations in difficult or doubtful cases, they should, in addition to their ordinary professional attainments, possess some special knowledge of morbid anatomy and of medical jurisprudence. And lastly, that it is incumbent on the State to appoint a public prosecutor in cases of suspicious death, and thus to obviate the necessity of private persons placing themselves in such odious positions that they may be accused of malicious motives, when perhaps they think that they are only performing what they believe to be a public duty. We are convinced, and so is now Dr. EDMONDS, that Dr. MILLETT is wholly and entirely innocent of any offence in reference to the death of his brother; but it might happen that, in some future case, a person really guilty of administering poison might escape from justice from the unwillingness of private individuals to place themselves in such invidious positions as those to which we have adverted.

THE DOUBLE QUALIFICATION IN IRELAND.

In some of our more recent numbers our attention has been called to the want of a double qualification, which, in the view of our correspondents, is just now imperatively demanded from the two Irish professional corporations, the King and Queen's College of Physicians and the Royal College of Surgeons, Ireland.

One of the gentlemen who has favoured us with his opinions on this subject, states, with reference to the Edinburgh "Double," "that fully a fifth of the students at present in Dublin intend going up at some period for the double qualification." He further states that this plan has become a great favourite, especially with those who do not intend to settle in Ireland. Cheapness it seems is its chief recommendation, but it has another—that by it the student is glad to get off his two examinations at once, and by no means desires to have a second ordeal hanging over his head when he has successfully endured the first. The suggestion is then made—that our two Irish Colleges should make an arrangement by which something like the Edinburgh plan might be available in Dublin; and the "argumentum ad hominem" is used—that it would pay well to keep the fees to themselves.

Another correspondent ("Medicus") states that the idea of our Irish double qualification is not new, that it has been considered, and that the difficulties to be encountered in making the desired arrangement are by no means insuperable.

To us it seems sound policy, and for the good of the state Medical, that something of the kind should be done, and that at once, so as to come into operation during the approaching summer. We do not presume to dictate to the learned gentlemen who sit on the seat of judgment in each of the Colleges as to the mode to be adopted in

giving effect to this recommendation, or the financial changes which it may be necessary to make to carry the plan into effect. We are well aware that it is not always easy for Medical bodies to agree on the question of fees, especially where each of them, as is happily the case in the present instance, regard the honour of their own body and of our profession as paramount to every other consideration, fees included; but we have no reason to form any other conviction than this—that should the question be brought before them in the form of a memorial from the students concerned, as recommended by "Medicus," it will be certain to meet with strong support and probable success.

There is one reason why such an attempt could be better made now than at any future time—namely, that Dr. BEATTY, the present President of the College of Physicians, is also an Ex-President and an Ex-Professor of the College of Surgeons. With both bodies he is deservedly popular, and his influence in this matter would go farther than that of any other single member of either College, however eminent he may be. Dr. BEATTY'S position with both Colleges is unique, and should be made use of. The principle of a double examination was in former years tested at the University of Dublin, where the Examiners of the College of Physicians joined with those of the former body in testing the merits of the same candidate, who, if he successfully passed the double ordeal, was entitled to admission to his Medical degree, and also to the licence of the College of Physicians. We cannot see why some such plan should not be adopted in the case now before us, and there is no reason why two Colleges should not agree as to the mode of dividing the fees. The constituent members of each, if placed on any other public boards, would readily make a deed of pecuniary agreement if they considered it to be for their interests to do so; and there is nothing in the *sensus communis* of our profession which peculiarly advocates obstructiveness, or refuses to progress with the age in which we live. It must be borne in mind by those who desire this double qualification that it may be found to materially alter the financial position of the Colleges. The College of Surgeons has no estates, and its income arises from the fees paid by candidates for its diplomas. These candidates are, however, numerous.

The College of Physicians is, in fact, in a somewhat similar position as regards sources of income; for, although it has estates, the funds arising from them are for the most part applied to purposes and to officers defined by Acts of Parliament, and so they are not available for general Collegiate purposes.

It must be also borne in mind that this College has already virtually conceded the principle advocated by our correspondents. Any Licentiate of the College of Surgeons, if provided with the necessary Certificates, can immediately come before the President and Censors for Medical examination. In such case the candidate is allowed to dispense with the first day's examination in Anatomy,

Physiology, Chemistry, and Botany; and so generally is this privilege taken advantage of that, from being at one time the exception, it is now all but the rule, since the cases of mere students examined on two several days by the President and Censors are comparatively rare. A Licentiate of the College of Surgeons is not required by the College of Physicians to answer in any other subjects than Medicine, Materia Medica, Medical Jurisprudence, and Midwifery.

QUACK ADVERTISEMENTS AND THE PUBLIC PRESS IN IRELAND.

OUR attention has been particularly called to an important letter from Dr. CUNNINGHAM, of Rathgar, which appeared in our impression of the 28th ult., deprecating the filthy quackery now becoming common in Ireland, and the systematic mode in which it seeks to attract public notice. It has been stated by some that our friends at the English side of the Channel were peculiarly susceptible of quack influence, that John Bull was gullible to the last degree in any matter connected with physicking, while poor Pat was scarcely accessible to the lying braggadocio of the quack or impostor; his natural and instinctive veneration for learned authority keeping all vampires medical at a long distance from him.

Of late, however, this has been much modified. Frequent intercourse with the sister country, we are told, has introduced to Ireland, among other blessings of civilization, the filthy advertising system of the large English towns, in its most dangerous and delusive guise.

We shall here confine ourselves to exposing one class of advertising:—that which, to the unprofessional eye, looks all right; while at the same time it is tenfold more dangerous than the honest advertising of the open foe to medical science and suffering humanity. We have been invited to read advertisements habitually published in two of the most respectable daily papers in the City of Cork—namely, the *Cork Constitution* and the *Cork Daily Herald*. The one circulates widely among the families and connections of the clergy of the Established Church, and of the landed gentry of the South—many of whom like to do the doctor occasionally, and dabble a little in homœopathy; the other is a well-edited commercial journal, conducted on moderate political principles, and having a very large circulation, not only in the County of Cork, but also throughout the South of Ireland generally.

We have cut out the following advertisement from the *Cork Constitution* of the 2nd Feb., 1866, and it is here given *literatim*, omitting only the address of the advertiser, whose business we have no desire to increase:—

Just Published, 3rd Edition, Price 1s., Post Free for 14 Stamps, with Photographic Illustrations,
SKIN DISEASES AND THEIR REMEDIES,
 BY ROBERT J. JORDAN, M.D.,
 Licentiate of the Royal College of Physicians, Edinburgh,
 Member of the Royal College of Surgeons, England,
 &c. &c. &c.

CONTAINING the modern treatment (as adopted at the Hospital of St. Louis, Paris) for the cure of those

numerous diseases so prevalent in a high state of civilization, too often consequent on an impure state of the blood, causing cutaneous eruptions, scorbutic affections and scrofula; treatment for superficial and deep-seated ulcers; torpidity of the circulatory system, causing discolouration of the skin, disfiguring the face and giving it an unsightly appearance, in lieu of a clear, fair, and healthy complexion.

"This book is, as he has aimed to make it, 'thoroughly useful and practical.'"—*Medical Times and Gazette*, August 4th, 1860. To be had direct from the Author.

We can vouch for the truth of the following result of the above *morceau*:—

A country gentleman, whose children were affected with cutaneous disease, read it in his morning paper, purchased the "work," and presented it to his ordinary medical attendant, a respectable provincial practitioner, who gave us the perusal thereof.

Now, this book being published, advertised, and having apparently the sanction of one of the most able Medical journals in the Kingdom, challenges criticism, and it shall get it. We beg to inform the editor of our contemporary, the *Cork Constitution*, that ROBERT J. JORDAN very carefully abstains from stating to what university he professes to belong—that he *was* a "Licentiate of the Royal College of Physicians, Edinburgh"—that he *was* a "Member of the Royal College of Surgeons, England;" but he is not now a member of either corporation.

So far we see that, while assuming the title of M.D., under which, however, he never was registered, Mr. JORDAN *was* in fact a duly qualified member of our profession; and that he was so is proved by the fact of his having at one time been registered as such under the Medical Act. BUT—he is no longer registered; his name has been erased by the Medical Council for reasons which they doubtless thought sufficient; and in the "black list" of names erased, published in the *Medical Times and Gazette* of March 17, 1866, the name of JORDAN figures at length.

How this occurred we shall shortly detail, and that in the words of the report published by parliamentary authority.

On page 157 of vol. ii. of "Minutes of the Medical Council," we find:—

"Read—The following letter from the Royal College of Surgeons of England:—

"Royal College of Surgeons of England, London, W.C.,
 May 8th, 1863.

"SIR,—I am desired to acquaint you that the Council of this College have removed Mr. Robert Jacob Jordan, of George-street, Hanover-square, from being a member of this College.—I am, Sir, your obedient servant,

(Signed) "EDMUND BELFOUR, Secretary.

"Dr. Francis Hawkins, Registrar, General Medical Council."

"Moved by Mr. Arnott, seconded by Mr. Lawrence, and agreed to:—

"That the Registrar be directed to erase from the Register the qualification of Mr. Robert Jacob Jordan as a Member of the Royal College of Surgeons of England."

Again, in vol. xiv. of the same Minutes, p. 66, we read:—

"Read—The following letter:—

"Royal College of Physicians, Edinburgh,
 November 5, 1863.

"SIR,—By direction of the Royal College of Physicians of Edinburgh, I beg to intimate to you, on behalf of the General Council of Medical Education and Registration of the United Kingdom, that, at a meeting of the Royal College of

Physicians of Edinburgh, duly called and held here on 3rd instant, the following Motion was submitted to the College and carried:—

“It having been proved to the satisfaction of the College, that Robert Jacob Jordan, a Licentiate of this College, has been guilty of conduct unbecoming the character of a Physician, in publishing, or causing to be published an indecent work, entitled, ‘the Illustrated and Descriptive Catalogue of the Subjects contained in the London Anatomical Museum; to which is annexed the guide to Masculine vigour—by a Physician; that the said Robert Jacob Jordan be deprived of his Licence from the College; ‘That the College thereon declared that the said Robert Jacob Jordan was deprived of his Licence from this College, conferred on him on the 14th June, 1859, and of all the rights and privileges which, as a Licentiate of this College, he does enjoy.’

“In intimating this deprivation of Mr. Robert Jacob Jordan’s licence from this College to you as Registrar of the General Council of Medical Education and Registration of the United Kingdom, the College directed me to request of you that any qualifications derived from this College and entered in the ‘Medical Register,’ as pertaining to Mr. Jordan, may be expunged.—I am, Sir, your most obedient servant,
“CHRISTOPHER DOUGLAS,

“Clerk to the Royal College of Physicians of Edinburgh.
“Dr. Hawkins, Registrar, General Medical Council of Medical Education and Registration.”

“Moved by Dr. Alexander, seconded by Dr. Andrew Wood, and agreed to:—

“That the name and qualification, as Licentiate of the Royal College of Physicians of Edinburgh, of Mr. Robert Jacob Jordan, be removed from the Register.”

We beg to call the attention of the Colleges above referred to to the fact that JORDAN still advertises himself as belonging to them.

On examining the second edition of this work, which appears under the guise of a third edition, we were surprised to find only an 8vo. pamphlet of a few pages, containing no proper treatise on skin diseases or their remedies, but a series of remarks, unfit for any female to read, on eruptions caused by syphilis, expressed in general quasi-professional terms, not at all entering into the syllabus given in the advertisement, and ending in the usual way—medicine, advice, and cure from the advertiser.

We asked ourselves could it be possible that the *Medical Times and Gazette* said, in 1860, that “this book is as he (JORDAN) has aimed to make it, thoroughly useful and practical?”

A reference to that journal showed that the review quoted as sanctioning this pamphlet, was really written, on quite another book, with the same title—a book of 284 8vo pages, published by Mr. CHURCHILL, the eminent London publisher. But JORDAN subsequently publishes a dirty pamphlet, to which he gives the same title, and applies to it the sanction of a review written on another book, and advertises the review of the *Medical Times and Gazette* as referring to his production now under our notice. Can any deceit or fraud be greater than all this? and can any respectable paper—now that we give the facts, which of course we did not expect non-professional men to know—continue to do such mischief to morality and health, as to circulate this guilty stuff for mere gain?

We give just one more advertisement, this time from the *Cork Herald*, of 3rd March, 1866, suppressing only the address of the advertiser:—

DISEASES OF WOMEN; a Treatise describing their Causes, Symptoms, and Treatment, illustrated with

Cases, with the names of cure used in each case, especially designed for the use of Females, whether Married or Single. Free by post on receipt of seven stamps. Address Dr. Smith.

Now, we ask the editors of the daily press to look into the *Medical Register* for the names of these pretenders ere they publish them, and to see if their works appear in the London publishers’ catalogues? Has the Editor of the *Cork Herald* sought for the name of this “Dr. SMITH” in the *Medical Register*, or for the name of his “work” in the London publishers’ catalogue? Does he know who his advertiser is, what is his professional status, and what medical journal has noticed his “work?” We say all this in utter ignorance of who “Dr. SMITH” may be. We know some most honourable men of the name, but none of them is the author of this “work.”

We wish the Irish College of Physicians would put their legal powers of inspection into force on the Dublin quacks. They have ceased inspecting apothecaries’ shops, but they may well turn the powers given them by Lucas’ Act to good account by literally “walking into” the shops of the quacks who now boldly do business before our eyes. Every man who cares for his wife and daughters should join us in attacking these wretches.

We shall feel obliged by any of our readers sending us Irish papers, which, notwithstanding our protests, continue thus to bring discredit on the fourth estate. With its many faults about Ireland, the *Jupiter of the Press*, the *Times*, has never disgraced its columns with a quack advertisement.

Notes on Current Topics.

THE POOR-LAW BOARD AND THE SICK POOR IN WORKHOUSES.

ALTHOUGH the question of the treatment of the sick poor in the metropolitan workhouses has been lately prominently brought before the public, and is still discussed in the columns of the journals, the Poor-law Board preserves the closest silence upon the subject; and it is quite impossible to understand whether it intends to initiate any movement for the amelioration of the existing disgraceful state of affairs, or even to follow the present current of popular feeling in bringing about a reform of the Workhouse Infirmarys. Our own opinion as to the supineness of the Board has been already expressed, and we are not disposed in any way to retract the expression of our belief that if it had done its duty the present agitation would have been unnecessary. With every respect for the motives of a contemporary journal in instituting a Commission to investigate the condition of the Metropolitan Workhouse Infirmarys, what necessity ought there to have been, we may ask, for such a step, when the Poor-law Board possesses a complete staff of well-paid officers and inspectors appointed for the very purpose of protecting the sick poor, as well as other classes of paupers? Why is it unnecessary for the *Lancet*, or any other journal, to inquire into the condition of Lunatic Asylums and Prisons, but because there are Government Inspectors who watch over the treatment of the inmates of these receptacles of insanity and crime, and who bring to light and correct any abuses they may discover. The Poor-law Inspectors have equal

opportunities of examining into the treatment of the sick poor; and as we assert without fear of contradiction that the abuses now disclosed have long been known to them, we regard these officials as equally culpable with the Guardians, whose misconduct the Poor-law Board ought at least to have exposed, if it could not punish. But the Board has consistently refused even to investigate the mismanagement of the Workhouse Infirmaries until quite lately, when it saw the current of public opinion drifting in favour of the sick poor, and then it makes a merit of doing what it ought to have done long ago, but which it has always neglected to do. Why does not the Board publish the reports it has received from its own Inspectors as to the state of many of the Workhouses, but because by so doing the Board would exhibit its own negligence. The Commissioners in Lunacy publish their reports on the condition of Lunatic Asylums, and why does the Poor-law Board withhold or suppress its reports on the Workhouse Infirmaries but because it has been aiding and abetting the Guardians in their shameful ill-treatment of the sick poor. The Board pretends, forsooth, that it has refrained from interfering with local management; but did the Government hesitate in abolishing the local constabulary and substituting the new police, or did it hesitate in appointing Inspectors to regulate Lunatic Asylums and Prisons? When these questions are answered satisfactorily we shall be able to defend the Poor-law Board, but not before.

THE ARMY AND NAVY MEDICAL OFFICERS.

WE would warn our military brethren, especially those of the army, not to be too sanguine that all the recommendations of the Select Committee lately appointed to report on the pay, rank, retirement, &c., of Army and Navy Medical Officers will certainly be adopted. We do not state that the authorities will refuse to act upon the report, but we merely mention that they have not yet done so. If our surmises are correct, we believe it will be found that the concessions will be made in the case of the Navy; but that in the case of the Army the authorities are still considering the question as to whether the concessions should be made or not, and the result will depend upon the circumstance whether a sufficient supply of candidates for the service can be procured under the existing regulations. The augmentation of pay proposed by the Select Committee is very considerable, and it will be necessary to make a new estimate of expenses by the War Department, if the recommendation should be carried into effect.

A LATE ELECTION AT BETHLEHEM HOSPITAL.

CONSIDERABLE interest has been recently excited among alienist physicians by the announcement of a vacancy in the post of Medical Superintendent of Bethlehem Hospital, and the appointment of one of the candidates on Monday week. As is usual in all elections where there are several competitors for the vacant office, the result has been distasteful to the unsuccessful candidates; but we must in all fairness admit that the Committee of the Hospital are not free from blame in the steps they have taken (and, as it turns out, successfully) to secure the election of their own candidate. The vacancy was caused in November of last year by the death of Dr. Helps, and

candidates were invited to come forward, certain qualifications being announced as indispensable, among which were the Doctorate in Medicine of a British University, or the Fellowship or Membership of the College of Physicians of London, Dublin, or Edinburgh. Among the candidates was the assistant medical officer, who, however, was not possessed of the qualifications referred to, and consequently it was supposed that the field was open. But of six candidates who presented themselves the Committee selected three, one being the assistant medical officer just alluded to, and the two others being gentlemen who had no intention of going to the poll. Thus, the other three being entirely excluded from the consideration of the general body of governors, the favourite candidate walked over the course. As we before remarked, we think the conduct of the committee was very unfair, and although we offer no remarks in disparagement of the gentleman now selected, we think that the others had not that legitimate chance of success which they had a right to expect.

THE RESIDENT MEDICAL OFFICER OF THE CHARTER-HOUSE.

A SMALL piece of patronage has just fallen to the clerical and legal dignitaries who regulate the affairs of the Charter-house, in the shape of the appointment of Resident Medical Officer to that ancient Institution. The establishment consists of boys on the foundation of the school, and of a certain number of old gentlemen who reside in the building, and enjoy certain privileges. Mr. John Miles, who has performed for several years the duties of Resident Medical Officer, to the satisfaction of every one connected with the building, has been induced to resign the appointment in consequence of advancing years, and it is whispered that some of the electors contemplated the perpetration of something like a job, by appointing a nominee of nearly the same age as Mr. Miles. Such has not, however, been the result; but the appointment has fallen on Mr. Nicholl, a surgeon in the army. It was hoped that a general practitioner (the class to which Mr. Miles belongs) would have been appointed, but that hope has not been realized.

THE CATTLE PLAGUE.

WE believe we may assert with truth that the cattle plague is diminishing in England and Scotland; Ireland, as is well known, having never been visited at all. It is true that the weekly returns are not quite conclusive, because some of the local Inspectors have not sent in their reports, but still the difference in the numbers is so great that in all probability the decline of the disease may be assumed as a fact. Whether the result is due to the operation of the Act which has just passed through Parliament, or to the recent coldness of the weather, or to other atmospheric causes, or whether the accession and the decline of the malady are to be regarded as phenomena equally mysterious and inexplicable by human reason, we cannot pretend to determine. We admit in all frankness that the diminished severity of the epizootic cannot be attributed to the successful application of medicines, but then it must be remembered that legitimate medicine never made any pretence of having discovered a cure. That boast was left to the homœopathic quacks and to experimenters like Mr. Worms, and their failure has been the more conspicuous from the boldness and the confidence with which their

several nostrums were recommended to the public. One result which was predicted by the opponents of the Cattle Diseases Act—namely, that the transit of the cattle could not be stopped without serious inconvenience, has certainly not been realized, and the metropolitan market, for instance, is so abundantly supplied with dead meat that prices have risen very little, while the public are so well satisfied by the absence of the living beasts from the thoroughfares, that it is even hoped that the slaughtering of cattle will not hereafter be allowed within the metropolitan precincts.

THE LONDON INFIRMARY FOR EPILEPSY AND PARALYSIS.

UNDER the above title an institution has been lately established in Charles-street, Portman-square, for the treatment of several diseases of the nervous system, the sufferers from which are excluded from most of the general hospitals. There is at present another institution, having similar objects in view, situated in another part of the metropolis, but this alone is obviously inadequate to receive the multitude of patients applying for relief. There is therefore ample scope for the new Infirmary, the operations of which are at present limited to the relief of out-patients; but as soon as the funds will allow, it is intended to open wards for in-patients. Dr. Julius Althaus, whose contributions to scientific Medicine are well known to the profession, is the honorary physician, and Mr. Alexander Ure is the consulting surgeon.

VACCINATION IN SCOTLAND.

WHEN the Scotch Vaccination Act came into full operation on the 1st of January, 1864, considerable speculation was excited as to how the Bill would work. All doubt as to the propriety of enforcing such a statute, and any fears which were originally entertained as to the success of such a measure, have been entirely dispelled by the first Annual Report of the Registrar General on Vaccination in Scotland, which has just been published. The report contains many topics of great interest and importance, but we have room for only a few extracts:—

“During the year 1864, according to these vaccination returns, 112,559 births were entered on the Birth Registers, of which number 3708 were those of children who, from having been born prior to the 1st day of January, 1864, were not included under the operation of the Vaccination Act. That number therefore being deducted, would leave 108,851 children in Scotland in 1864 under the operation of the Act. With that number, therefore, we have alone to do.

“Of the 108,851 children, 95,047, being 87·32 per cent. of the whole, were successfully vaccinated. 662, or 0·61 per cent., had their vaccination postponed from ill-health or other causes. 1261, or 1·15 per cent., were found to be insusceptible of vaccination; but of these the insusceptibility arose from the child having been previously vaccinated in 440 cases, from the child having had small-pox in 154 cases, while in 667 cases it arose from constitutional insusceptibility. 9180 children, or 8·44 per cent., died before vaccination could be performed; while 2701 children, or 2·48 per cent., had removed from the district before vaccination could be enforced, or were otherwise unaccounted for.

“The above statement does not bring out the full success of the Vaccination Act, so as to make it patent to every mind. What we are specially interested in ascertaining is not the proportion successfully vaccinated out of the total number of children whose births are entered

on the Registers, for that includes all who died previous to vaccination; but we wish to ascertain what proportion of children, who survived till they were vaccinated, are protected by vaccination. Deducting from the 108,851 children who came under the operation of the Act, the 9180 who died before vaccination was attempted, 99,671 living children are left to be operated upon. Their vaccination gives the true success of the Act, and is of extreme interest.

“Of these 99,671 living children, 95,047, or 95·36 per cent., were successfully vaccinated; but as we must add to that number all those who were found to be insusceptible of the vaccine virus, from having been previously successfully vaccinated by clergymen, midwives, or parents, all those who had already had small-pox, and all those who had constitutional insusceptibility, we find that those really protected amount to 96,308 children, or to the proportion of 96·62 in every 100 children. As all those whose vaccination is postponed are being looked after, and those who survive will be vaccinated, this gives us a total of 96,970 children out of 99,671, or a total proportion of 97·29 in every 100 children, protected as far as may be from the ravages of small-pox. In fact, it accounts for every living child, excepting the 2701 who have been lost sight of, from their parents having removed to other parishes. Only the small proportion, therefore, of 2·71 per cent. remains unprotected by vaccination of all the living children who came under the operation of the Vaccination Act in 1864.”

These statistics show a most extraordinary success in the working of the Act; indeed, we question whether any statute during the first year of its enforcement was ever more thoroughly or efficiently carried into effect. On this point the Registrar remarks:—

“The proportion successfully vaccinated in Scotland is about the highest which could be vaccinated out of the numbers given, and reflects the greatest credit on the people and on the vaccinators.”

With regard to the mortality from small-pox, it is satisfactory to know that the number of deaths from that disease has been lower during the last year than for the last eleven years, and there can be little doubt that the Vaccination Act has had some influence in diminishing the number of fatal cases.

“The deaths from small-pox over all Scotland for the two years during which the Vaccination Act has been in operation cannot yet be ascertained, as the registers for 1865 will not be received at the head office for some months, and it takes several clerks many months' labour to extract and tabulate the causes of death, &c. But the deaths from the different diseases in the eight principal towns of Scotland are tabulated monthly; so that we can ascertain from them whether small-pox has increased or diminished since vaccination has become general.

“It was found that, by taking an average of eight years, there died from small-pox in Scotland annually 895 persons, and that 487 of these deaths occurred in the eight principal towns. This shows that more than one-half of the deaths from small-pox in Scotland occur in eight towns; so that if we know the number of deaths from small-pox in these eight towns, we can arrive at a very close approximation to the number of deaths from small-pox over the whole of Scotland.

“In 1863, the year before the Vaccination Act came into operation, 816 persons died from small-pox in the eight towns, indicating a mortality of 1500 persons over Scotland during that year from that disease. In 1864, the deaths from small-pox in the eight towns were 679, implying that 1248 deaths over Scotland occurred that year from small-pox. In 1865, which may be regarded as the first year in which the Vaccination Act was in full operation, the deaths from small-pox only amounted to 67, which only implies 123 deaths from that disease over

Scotland. Never for the last eleven years has the mortality from that disease been half so low; and making every allowance, it can scarcely be doubted that the general adoption of vaccination has had considerable effect in reducing the mortality."

The Report also contains some remarks as to the fees charged for vaccination, from which it appears that many of the country people, who in former times were accustomed to have the operation performed gratis, either by the clergyman of the district or a midwife, now grumble very much to pay 1s. 6d. or more for it. But we never could see the reason why medical men should not be paid for vaccinating a child as well as for any other service. It is the custom even yet in many places for the accoucheur to do this little operation without any further remuneration than the fee for the confinement. But why should this be? The practitioner might just as well be expected to amputate a patient's limb or remove a scirrhus breast free of charge, just because he had attended her in labour! If the people are paupers, let them have every facility granted to them for having their children vaccinated gratuitously. But it is, in our opinion, most iniquitous and unfair, that persons who are in the receipt of weekly wages, and who are in the habit of paying the doctor for ordinary attendance, should expect him to take the trouble to vaccinate their children without remuneration. The mere fact of their being called on to pay a small sum undoubtedly has the effect of making them regard the operation as a thing of some importance, whereas gratuitous vaccination has the tendency to make them careless, and to give them the idea that the whole affair is a trifle which may or may not be done, according to pleasure.

Correspondence.

DR. RICHARDSON ON LOCAL ANÆSTHESIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR,

SIR,—Mr. Symes' letter of March 7th "On Local Anæsthesia" requires a line or two in reply from me. In the first place, let me state that my instrument has *not* been patented, and that there is no shadow of a reason for any statement to that effect. The instrument which Mr. Symes refers to as having been used by himself in substitution for mine is the one I originally used—viz., a Berjens's spray tube with Dr. Clarke's hand-ball bellows. I was obliged to set this aside, except the bellows part, as inferior, and Mr. Symes will do the same, I think, when he has worked at the subject as long as I have. Berjens's tube does not produce the same rapid degree of cold nor the same extreme degree as mine; it cannot be moved in operations with the same ease and rapidity, and it does not admit of being made into a multiple instrument. As regards fineness of spray from my instrument, that is entirely under the control of one operator. By altering the regulation needles a spray finer than any produced by the suction process is secured; but in some cases a coarser spray is required, and then by changing the needle that can be effected.

In the third place, as regards the relative merits of ether and chloroform, Mr. Symes will find after a time, I believe, that ether is best. Chloroform has no advantages over ether as an anæsthetic; it is slower in its action, its boiling point being so much lower, and it produces insensibility much less deeply; but the worst feature of it is, as I found in twenty-two experiments, it leaves sometimes an intense vascularity of surface, almost an erythema, with peeling of the cuticle and considerable pain.

In my earlier inquiries I used chloroform, also a mixture

of ether and chloroform of varying strengths, thinking that the chloroform exerted a specific action on open surfaces. Experience showed me that when two cases were carefully compared, the ether did the same in effect, uncombined as combined.

I sometimes, however, still use a mixture of chloroform and ether, in cases where, I think, it is not requisite to produce deep anæsthesia, as in puncturing an abscess.

In the fourth place, Mr. Symes mistakes somewhat the phenomenon of whitening of the skin, to which he raises objection. That phenomenon is producible without the necessity of any touch of the skin or prick of a needle. With my instrument in good action it occurs, if absolute ether be used, in the majority of persons, in fifteen seconds, and disappears as quickly. There is no objection at all in this process of whitening (freezing), because recovery from it is immediate and perfect, and it tells the fact that there is a superficial insensibility which may be extended to the depth of half an inch by a few more strokes of the bellows.

Whether absolute whitening of the skin should or should not be produced turns on the nature of the case and the wish of the surgeon. This is a practical point that should be well understood. If the surgeon does not wish to produce whitening and hardness of skin, he must mix one part in four of alcohol or chloroform with the ether, when, if he continue the spray three or four minutes, he will get anæsthesia. If, however, he should wish to narcotise very quickly, he will use absolute ether, and get the result in an eighth of the time. By practice I can get the anæsthesia with ether in any degree by altering the distance at which the spray is delivered on the part.

According to the time employed in producing local anæsthesia, the sensations of the patient differ. A narcotism of four minutes implies a considerable although bearable degree of the sensation of numbing cold. A narcotism of thirty seconds implies a sudden, prickly, heated sensation, which some persons feel more than others. My experience, derived from over two thousand observations, leads me, contrary to my first idea, to favour the quick process. In many operations, where the patient could not see what was doing, I have produced insensibility, and the surgeon has operated before the patient knew the operation had commenced. In one case of carbuncle the whole mass was rendered insensible and divided from base to apex in fifteen seconds. At the same time, I admit that this point of rapid as opposed to slow local anæsthesia deserves careful consideration, and I hope Mr. Symes will be good enough to try both methods and report on them.

Allow me, Sir, in conclusion, to state how profoundly gratifying it is to me to observe the warm interest my brethren on the other side of the Channel are taking in my labours. I read all their observations as respectfully as critically, happy at all times to learn from them, and to communicate back again that which Nature, when she answers my childish questioning of her, deigns to reply.—I remain, Sir, your obedient servant,

B. W. RICHARDSON, M.A., M.D., F.R.C.P.

London, 12, Hinde-street, W., March 12, 1866.

THE FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Your editorial observations on the subject of the Fellowship of the Royal College of Surgeons gratified me greatly; and although I am not an advocate for another "year of grace," still I believe that the portals to the highest position in the College should be thrown open to a certain grade in the profession.

In the army, when a Surgeon has served twenty years he becomes Surgeon-Major; and I would say when a Licentiate

of the College has for twenty years honourably discharged the duties of his profession, and is well reported of by his brethren, he should be eligible for the Fellowship without having to submit to any further examination.

There are many Licentiates like myself, of more than twenty years' standing, who have borne the burden and heat of the day, and rendered the state some service, who now, in their declining days, would gratefully accept and gladly pay for the honours of the Fellowship, but who are not prepared after some thirty or forty, or perhaps fifty years' practice, to submit to an examination.

Hoping you will press this matter upon those in authority, I am, dear Sir, yours very truly,

February 27th.

A MILITIA SURGEON.

THE DOUBLE QUALIFICATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondents are both in error as to the reason that Irish Medical Students go to Scotland for their degrees. I studied in Dublin four years, at the Royal College of Surgeons, but took my degrees in Scotland; my reason being that the examination of the Irish College is what is called *crury*, and is therefore not a fair examination for a young student. Candidates are asked such questions as to give and trace relations of the median nerve. Does such a question test the student's common practical anatomy? Minute questions like the above, and others that can do a Medical man no earthly service, form a considerable part of the examination. These are the reasons why the Irish students go to another country for their degrees. Many of the Professors in Dublin could bear me out in what I have said, and could afford undoubted evidence of the causes of the exodus, the reasons, some of which I have stated above.—I am, Sir, your obedient servant, ALBERT EDWARD LANE, Surgeon and Physician.

Newtownlimavady, March 15th, 1866.

[Whatever truth there may be in Dr. Lane's strictures on the examination of the Royal College of Surgeons, we are under the impression that, if they exist at all, they are not the real reasons for students seeking their qualification elsewhere. Nevertheless, it appears to us that the great aim of the examination is to ensure practical competency in the Licentiates of the College, and that questions which go beyond this should be regarded as of secondary importance. Could the examiner who asks such a question answer that his candidate was perfect in practical surgery? If not, we would advise the adjournment of such questions till he has satisfied himself on the subject.—Ed. M. P. C.]

"NOTHING LIKE LEATHER."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Though the following extract, taken from the Year book of Medicine and Surgery for 1860, p. 463, proves that Chloroform afforded relief from pain in the passage of gall stones, it at the same time shows that its adoption for such purposes is not so recent as Dr. Kidd would lead us to suppose, and also, though used in large quantity, it unfortunately failed to result in as *beautiful a cure* as that he records:—

"A photographer, æt. 40, had suffered for six or seven years from gall stones, on account of which he had taken gradually increasing doses of morphia to the extent of 12 grains daily, but had subsequently diminished his dose to 1½ grains. From this time, whenever the pain increased, he was in the habit of inhaling in the course of a few days four to five pints of ether, and from eight to thirty ounces of chloroform, which afforded him relief, but subsequently produced erapular pains, which drove him again to the laudanum. He had in the meantime several attacks of mania, but showed himself to be a capable workman during the intervals. One morning Dr. Buchner found him in bed in the condition produced by long inhalation of chloroform and breathing tran-

quilly. An hour afterwards he died. Subsequently all the organs were found unaltered except that the gall bladder contained 72 small gall stones, and one as large as a bullet was found in the gall ducts."

Yours, &c.,

GARYONE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you kindly inform me through your next number of your CIRCULAR whether it is compulsory for a gentleman to pass the preliminary examination at the London College or at Apothecaries' Hall, who was indentured in July, 1858, and who has fully served his apprenticeship, and has been living with a surgeon ever since; and must he pass the preliminary before he can enter on his hospital practice studies?—I am, &c.

A SUBSCRIBER.

[Under the circumstances mentioned, the preliminary examination in arts would be dispensed with. The act did not come into operation until August, 1858.—Ed. MEDICAL PRESS AND CIRCULAR.]

PARLIAMENTARY INTELLIGENCE.

HOUSE OF LORDS.—MARCH 13TH.

CATTLE PLAGUE RETURNS.

The Earl of CARNARVON begged to call the attention of the noble lord the President of the Council to a matter of some consequence. We had come to that stage of the cattle plague when it was of the utmost importance to have correct returns. For some four or five weeks past the returns issued by the Veterinary Department of the Privy Council Office were very inaccurate. A certain number of inspectors, whether from being overworked or indolent, had not made returns, and the consequence was that last week there were 246 districts from which those returns were in arrear.

Earl GRANVILLE said that inspectors had been sent down to various districts from which no returns had been made to see what could be done.

MARCH 15TH.

Lord GRANVILLE, in reply to a question from Lord ELLENBOROUGH, stated that any magistrate who should improperly grant a certificate for the removal of cattle without a compliance with the conditions prescribed in the Orders in Council, would be liable to prosecution and dismissal from the magistracy.

HOUSE OF COMMONS.—MARCH 9TH.

HOUSES OF THE WORKING CLASSES.

Mr. T. HUGHES thought to get an alteration made in the Standing Orders, so as more effectually to protect working men from eviction from their homes by invading railways. He failed, however, and had to withdraw his motion.

EXCLUSION OF THE CATTLE DISEASE FROM IRELAND.

Mr. MAGUIRE asked the Attorney-General for Ireland whether his attention had been called to the case of a drover who, on his return from Cardiff to Cork, had three fresh calf-skins tied up in a bundle which he sought to conceal; and whether instructions would be given to the police in the various Irish ports to institute such scrutiny as would prevent the risk of the cattle disease being introduced into Ireland by similar means.

The ATTORNEY-GENERAL for IRELAND replied that he would cause inquiries to be made with the view of ascertaining the facts and of instructions being given to watch every circumstance of the kind referred to by the hon. member for the city of Cork.

SMOKE NUISANCE.

Sir ROBERT PEEL drew attention to the nuisance arising from the smoke of furnaces in towns and country districts, and in doing so animadverted upon the frightful

waste which, for want of proper regulations, now took place in our most valuable fuel, and the destructive effects arising therefrom to human life and health and to the vegetation in the neighbourhoods of large centres of manufacturing industry, and called upon the Home Secretary to give an assurance that the Government were prepared to legislate on the subject during the present session.

Sir G. GREY said he had directed an inquiry to be made in the principal towns as to the means which had been taken to enforce the law in particular places, and he had no doubt that the result would be to throw light upon the defects in the law, and point the way to improvements in the future, in which case he should be prepared to bring in a measure embodying such amendments as might seem to be advisable.

THE CLERKENWELL GUARDIANS.

Mr. KINNAIRD wished to know if instructions had been issued to the guardians of the poor of Clerkenwell to correct the evils which had been proved to exist in the casual ward of that parish, and if the Poor-law Board had power to enforce such instructions, if issued.

Mr. VILLIERS said that Clerkenwell was a portion of the town not within the jurisdiction of the Poor-law Board, but they had claimed the right to visit and inspect the workhouse; and for some years past, particularly of late, strong remonstrances had been made as to the treatment of the poor. Visits had been made by inspectors both by night and by day, and it was now in a better condition; but the guardians considered themselves quite independent of the authority of the Poor-law Board, and had been acting in defiance of it. He would not take upon himself the responsibility of introducing a Bill to extend the jurisdiction of the Poor-law Board without further inquiry.

MARCH 13TH.

THE RINDERPEST AMONG SHEEP.

Mr. LONG asked the Secretary of State for the Home Department whether the Government was taking any steps to ascertain if the disease resembling the rinderpest which had recently been observed among sheep in different parts of the United Kingdom was really the rinderpest or not.

Mr. BRUCE said that during the last six months the attention of the Veterinary Department of the Privy Council had been directed to this subject, and during that time twenty-six different phases of the outbreak of what was supposed to be the rinderpest had been reported in eleven counties, as many as seven occurring in the county of Norfolk. The conclusion at which the veterinary surgeons of the Privy Council had arrived was that the disease was identical with the rinderpest among cattle. This conclusion had been arrived at after a series of careful experiments conducted by Professors Simonds and Brown.

MARCH 14TH.

On the consideration of the Lords' amendments to the Cattle Plague Bill, after a long conversation,

Mr. T. G. BARING announced that if Mr. Hunt would withdraw the Bill the Government would undertake to strengthen the Privy Council Office, and would issue orders for the isolation of infected districts, the protection of disinfected districts, the regulation of fairs and markets, the cleansing of railway trucks, and other matters, on principles which he explained.

Mr. HUNT acceded to this proposal, and, on the motion of Sir G. GREY, the Lords' amendments were ordered to be taken into consideration that day six months.

COUNTY INFIRMARIES (IRELAND) BILL.

Mr. POLLARD-URQUHART, in moving the second reading of this bill, said that as the law stood at present an annual subscription of three guineas was required to constitute a governor of a county infirmary. The obvious effect of this provision was to limit the number of subscribers, and the bill, therefore, proposed that a subscription of a guinea

a year should constitute a governor, and one of ten guineas a life governor. He had, however, inserted a clause securing to those who gave the higher subscriptions a proportionate degree of influence in the elections of medical officers, &c.

The ATTORNEY-GENERAL for IRELAND remarked that the subscription by grand juries in Ireland to county infirmaries was at present optional, but it was proposed by this bill to make it incumbent on them in future to present the average annual sum which they had presented for the last ten years. This was a proposal of a most objectionable character, for circumstances might so alter as to render the continuance of the payment inexpedient, and, in fact, in the opinion of the Poor-law Commissioners, the workhouse hospitals had superseded the necessity for these infirmaries.

Mr. BAGWELL was of opinion that one or two infirmaries of a superior description in the different counties would serve a very useful end, by treating serious disorders and accidents with more care than was possible in a local workhouse. Not that he wished to disparage the medical officers of workhouses, many of whom were men of considerable eminence in their profession, but it was well known that in certain cases it was desirable to call in more advice than could be obtained from any one physician in any one place (hear, hear.) He did not ask for the revival of the Government grant to the officers of the infirmaries, which had gradually been allowed to drop, for he was always an advocate for the Irish people doing for themselves what the people of England did in like cases; but he hoped the Government would promise to deal with the subject, and that when the Chief Secretary for Ireland was in his place, which he trusted, after what occurred on Monday night, would be very shortly, a bill in accordance with what he had shadowed out would be introduced. He would advise the honourable member for Westmeath to withdraw his bill on such an undertaking, or else to ask the Chief Secretary in committee to assist in modifying it in any way that seemed best.

Sir H. BRUCE differed *in toto* from the opinion which had been expressed that these infirmaries had been superseded by workhouse hospitals. The fact was that they benefited a class of persons who were unable to pay for superior medical advice, but who yet, with a commendable pride, would never enter a workhouse hospital.

Mr. SYNAN objected to the compulsory clause as to grand juries, but with that exception cordially approved the bill.

The second reading was negatived without a division.

POOR-LAW MEDICAL REFORM AND VACCINATION.

Mr. GRIFFIN begs us to inform the Poor-law Medical Officers that the following subscriptions have been received by him towards the funds of the Association:—

Fendich, R., Bristol, 5s.; Wotton, C. H., Hempstead, 21s.; Thom, A., Brampton, 5s.; Phillips, G. M., Hitchin, 10s. 6d.; Stear, H., Saffron Walden, 5s.; Walsh, F. F., Saffron Walden, 5s.; Jones, A. N., Saffron Walden, 5s.; Rake, B., Forndingbridge, 5s.; Mott, C., Chertsey, 10s.

By Mr. Prowse—Davies, E., Wrexham, 5s.; Foster, J., Chorlton, 10s. 6d.; Waller, J. S., Flegg-Burgh, 5s.; Ifuke, S. T., Tunstead and Happing, 5s.; Ingham, A., Haworth, 10s.; P. R., 5s.; Lisle, R. P., Cardiff, 10s. 6d.; Wardlesworth, Bury, 10s. 6d.

The Vaccination Bill was read a second time on the 8th of this month; and therefore, those medical men who wish the bill amended in Committee should lose no time in writing to their members.

THE WATER-SUPPLY OF THE METROPOLIS.—A meeting was held a few days ago, at which Lord Ingestre presided, when attention was directed to the filtering apparatus which the London and General Water Purifying Company supply, and which Government has recently adopted in two or three instances with complete success.

Medical Obituary Notices.

WE regret to have to announce the death of Major John J. Corrigan, of the 3rd Dragoon Guards, eldest son of Dr. Sir D. J. Corrigan, Bart. The deceased gentleman died in Australia, where his regiment was stationed. He was, we understand, married, but left no heir male, so that Dr. Corrigan, a member of the Irish Bar, is now heir to his father's baronetcy.

DEATH OF DR. O'REARDON.

DR. O'REARDON, whose death took place on Wednesday last at Killarney, had reached the patriarchal age of 90, and was the oldest member of the College of Physicians. Mr. O'Reardon entered in 1797 the College of Maynooth. A pause in his speech having unfitted him for the pulpit, he relinquished theological for physiological studies, and in 1802 he became a physician. During this year he published in Latin some medical dissertations, dedicated to Drs. Clarke and Purcell. Sound sense, free from the theorising flights to which some young physicians are prone, characterise these productions, while their Latinity is pure and vigorous. In 1803, Dr. O'Reardon proceeded to France for the purpose of gathering experience at the hospitals of that city, and of enjoying the advantages of a course of instruction under the celebrated Baron Cuvier. Prolonged hostilities between France and England sprung up shortly after, and Dr. O'Reardon, together with his grand uncle, the General Count O'Connell, of the British service, with whom he resided, were detained in France until the restoration of the Bourbons, nine years later. The longevity of the family is remarkable, General O'Connell having attained the age of 91 at his death in 1834. In 1814, Dr. O'Reardon returned to Ireland, and became physician to some public institutions, from which he received formal addresses of thanks; but it is in connexion with the fever hospital in Cork-street with which he will be chiefly remembered. For thirty years he was, with the late Dr. Harkin, its zealous and efficient medical attendant; but on the reduction of the hospital grants in 1848 his services were relinquished. The medical reports of the hospital, of which many exist, from his pen, attest the unremitting zeal with which Dr. O'Reardon watched over the patients committed to his care. He was also the writer of a small memoir of Kirwan, the eminent chemist, whose friendship he possessed. He was the associate in consultation with Colles, Cheyne, Crampton, and Carmichael; and, although he did not hold quite as high a rank as those eminent names, he largely shared their friendship and high opinion. Dr. O'Reardon was first cousin of Daniel O'Connell, whose family physician he had been.

JOHN CONOLLY, M.D.

THE *Lancet* publishes the following particulars of the life of this distinguished physician:—

Dr. Conolly entered life at the age of eighteen as an ensign in a militia regiment. In 1818 he married Elizabeth, a daughter of Sir John Collins; and it marks the energy and determination of his character that soon afterwards he entered himself as a student in the University of Edinburgh, and took his degree with distinction in 1821, selecting "Insanity" as the subject of his thesis in graduating as Doctor of Medicine. After some further prosecution of his medical studies in Paris, he engaged in the practice of his profession for a short time at Chichester. He then removed to Stratford-upon-Avon; he was there to some extent successful, and much liked, being twice elected mayor of the town. In 1827 he came to London; there his charm of manner and his real talent engaged the attention of Lord Brougham, and, mainly through that nobleman's influence, Dr. Conolly was appointed Professor of Medicine in the University of London, a great

distinction for so young a man. During the four years he retained this chair Dr. Conolly engaged much in literary work, in conjunction with Dr. Tweedie and Sir John (then Dr.) Forbes; he edited the "Cyclopædia of Practical Medicine," contributing many articles. In 1830 he published his first and best work, the "Indications of Insanity." His other publications were, a work "On Asylums," 1847; a volume "On the Non-Restraint System," 1856; an "Essay on Hamlet," 1863; his admirable "Lectures" published in the *Lancet*, and those delivered before the College of Physicians. There is much of his writing in the Annual Reports of the Hanwell Asylum, 1839 to 1842. Those written by him are models of composition and of sound practical sense. In 1830 Dr. Conolly returned to the provinces, and became inspecting physician to the asylums in Warwickshire. In 1839 the great wish of his life was gratified by his appointment as Physician to the Hanwell County Asylum.

In spite of his great and varied talent, the biographer of the *Lancet* thinks that Dr. Conolly would never have attained any distinction as a general consulting physician: the defects of his early training, his desultory education, and the late period of his life at which he entered upon the study of medicine, combined to prevent his obtaining any mastery of its principles, or ever feeling that pleasure in its practice without which no physician can hope to become famous. In his appointment to the direction of the Hanwell Asylum, Dr. Conolly found the exact field fitted for his genius. He had an intellect prompt at analysis: the functions of the mind in health, its deviations in disease, had been his favourite study. In his diagnosis of mental disorders he was singularly happy; and the natural kindness and benevolence of his heart made the system of treating the insane without mechanical restraint, which he inculcated with so much ardour and success, a labour of love indeed.

It is a mistake to suppose that Dr. Conolly originated this system. Without him it probably never would have attained its present development, and might possibly have been strangled in its birth; but to Dr. Conolly the merit belongs of inaugurating a new feeling in relation to the insane—gentleness and kindness, the utmost forbearance, the most tender pity for those under his care, was the example he set and the lesson he inculcated. A new school of physicians arose under his auspices; and, to again quote Lord Shaftesbury, Dr. Conolly "was an eminent instrument in a great work of wisdom and humanity." The labours of Dr. Conolly were fully appreciated by his professional brethren. Few men had so many devoted friends. He was for years a Vice-president of the Medical Association, and on the unanimous vote of its members obtained the honour of the degree of D.C.L. from Oxford at the same time as Sir John Forbes and Sir Charles Hastings. He was twice President of the Medico-Psychological Association, and counted among its members his most loved and cherished friends.

DEATH OF SIR ALEXANDER MORISON.

FOLLOWING closely upon the death of Dr. Conolly, which was recorded in our issue of last week, another distinguished authority on insanity has passed away full of years and honour. Sir Alexander Morison, M.D., and Fellow of the Royal Colleges of Physicians of London and Edinburgh, died at Balerno-Hill House, near Edinburgh, on the 14th inst., aged 87 years. He is well known as the author of various works on insanity, and just a short time ago founded a lectureship on that subject in connexion with the Edinburgh College of Physicians, to which Dr. Sellar was appointed. Sir Alexander was at one time President of the College, and received the honour of knighthood so long ago as the coronation of Her Majesty. An excellent portrait of this distinguished physician was painted for the College about two years ago by Sir John Watson Gordon.

RETROSPECT OF MEDICAL JOURNALS.

MARCH 17TH.

THE journals of the week are singularly devoid of news.

It is gratifying to find that the rinderpest is on the decline. Under the head of "Failures of the Infalible," the *British Medical Journal* disposes of Mr. Worms, whose garlic treatment of the Cattle Plague was so lauded by the *Times*. Although unsuccessful, Mr. Worms does not acknowledge himself beaten, and hints that his method has not had a fair trial. It seems to us that the state of the vegetable market is a direct measure of the extent to which this savoury treatment has been pushed. We read that the garlic has jumped from 3d. to 2s. per pound. Lord Ellenborough does not seem to have given up all hopes of a perfect cure:—

"The Earl of Ellenborough asked what was the use of talking of Mr. Worms' medicine or any other medicine if Parliament declared that all cattle, when once attacked, must be slaughtered? It was our duty to endeavour to cure it and overcome the calamity. We had a letter from the consul at Warsaw, which distinctly declared that the disease had been cured; and only the other day we heard of this remarkable occurrence:—Three-fourths of a herd were slaughtered because they had the disease; and, as well as he remembered, seven more were condemned. For some time these seven would not drink; but, having been turned to water in which lime had been slaked, they did drink, and were well in a few days. With such facts before us, were we to say the disease was incurable? We should be guided by experience, and not by learned disquisitions, which required that a man must have read extensively before he could understand them. We never should get rid of this cattle-plague till we had got rid of the plague of trusting to professors rather than to common sense."

It is astonishing to observe how many persons apparently endowed with sense and the ordinary amount of intelligence, are caught by any clap-trap, no matter how absurd and irrational. In a disease like the rinderpest it is clear that if any means of cure be really successful it will be the result of logical reasoning imparted to us much in the same way that Jenner gave to the world vaccination for small-pox. We would recommend Lord Ellenborough to leave the cattle plague to the learned professors he so much despises. Every man had much better stick to his own trade.

In the case of the manufacturer of ketchup who was summoned before Mr. Woolrych for using pig's liver in the process as a substitute for mustard, the magistrate dismissed the summons as it was not proved that ketchup was an article of food; on the same grounds beer, wine, confectionery, and many other substances in daily use could be adulterated with comparative impunity. It is to be hoped that the Court of Queen's Bench will not take the same view of the matter.

Mr. T. Wells has used Dr. Richardson's method of local anaesthesia in a case of ovariectomy, during the incision of the soft parts; the tumour contained 64lbs. of fluid, and was itself 5lbs. in weight.

We have a paper by Dr. B. Foster on the sphygmograph devised by Marey for investigations on the pulse; although invented for physiological purposes, it is now being used extensively in this country in disease.

The *Medical Times and Gazette*, under the head of "A Sad Tale of Mismanagement," refers to the late terrible loss of life among the troops at Hong Kong. It appears that a good deal of blame must be borne by the War Office, in that they disregarded the oft-repeated complaints as to the absence of accommodation for an additional regiment. Unfortunately the principals of the Medical Department were absent at Japan, and were unable to cope with the difficulty from a distance. Their absence is the only point in the whole business in which blame can be attached to the Medical Staff.

A correspondent, A. M. E., who must have been a follower of Edgar A. Poe, gives several instances of persons buried alive.

Medical News.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise on the 8th inst.:—

Bush, Richard Hake, York-terrace, Regent's-park.
Pugh, Richard, Llandoverly, South Wales.
Rickard, Frederick Martyn, Stoke Devonport, Devon.
Rugg, Robert, Dispensary, Steppney.
Wad, Frederick John, Priory-road, Kilburn.

The following gentleman also on the same day passed his first examination:—

Duke, Benjamin, Guy's Hospital.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—The following gentlemen passed the examination on the 14th inst. as Pharmaceutical Chemists:—

Alfred Barrowclough, Miffield,
William Beckett, Heywood,
Robert Keevill, Clifton,
James John Owles, Great Yarmouth,
William Phillipps, New Cross Road,
Joseph Spencer Robinson, Alfreton,
Philip Stoneham, London,
Samuel John Weston, London.

MR. BAKER BROWN has just been elected a member of the Medical Society of Christiania, in recognition of his services in operative surgery.

We learn with regret that Mr. Bolton, a medical student, studying in Dublin, died yesterday after only a few hours' illness, of a most virulent seizure, the nature of which is attended with the utmost obscurity. He had been in perfect health on Sunday evening, and in spite of the most assiduous attention and the first medical advice in the metropolis, died on Monday afternoon.

THE CHOLERA IN GERMANY.—The cholera has broken out with great virulence in some swampy villages of the Grand Duchy of Luxembourg and the adjacent district of Rhineland.

ROYAL HOSPITAL FOR INCURABLES.—The anniversary festival of this institution was celebrated on the 9th inst. by a public dinner at the London Tavern. The secretary announced a list of subscriptions, amounting in all to £2100.

ODONTOLOGICAL SOCIETY.—At the ordinary monthly meeting, held at its rooms, Soho-square, on the 5th inst., Mr. Mummery read a paper "On Certain Forms of Irregularity of the Teeth," exhibiting models of cases where great success had followed his efforts to reduce the deformity.

THE CHOLERA IN ALEXANDRIA.—Official information on the 11th inst. received from Alexandria by telegraph states that cholera has reappeared there. The Government of Malta has placed all arrivals from Alexandria in thirty days quarantine.

The Governors of Steevens' Hospital have agreed to open their wards for the training of nurses. Mrs. Trench has taken the subject up: with her influence and the opportunities of a large general hospital, it is to be hoped that her charitable effort to furnish the poor in hospitals and the rich in their own homes with properly trained nurses will be successful.

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS, IRELAND.—The sixth meeting (Session 1865-66) will take place on Wednesday, 21st of March, 1866. Tea at eight, chair to be taken at half-past eight, p.m. Discussion: On Dr. Belcher's paper on Diphtheria, read at last meeting; Communications: 1. Dr. Hayden, "On some Cases of Diphtheria." 2. Dr. Madden, "On a Remarkable Case of Mania, leading to attempt Murder and Suicide." 3. Rev. Prof. Haughton, F.T.C.D., "On the Geometrical Form of Gall Stones."

PARLIAMENTARY VOTE.—The following vote has been agreed to in the House of Commons: £246,500 for the army hospital establishment.

VACCINATION AND CATTLE-PLAGUE.—M. Bouley states that all the vaccinated cows which had been sent to England, in order to be placed in contact with diseased cattle, so as to test the amount of immunity acquired by vaccination, had taken the complaint.

ADVANCED PAYMENTS.

SUBSCRIBERS are reminded that their subscriptions in all cases must be paid within two months of the date of the order to secure the advantage of the lower rate of £1 1s. 8d. per annum, and that any subscription delayed beyond that period will be charged on the credit scale of £1 2s. 6d. per annum.

Contributors are requested in all cases to forward their communications direct addressed to the Editor of the special department of the Journal in which they reside. Considerable delays have arisen in consequence of matter from England being forwarded to the Editor of the Irish or Scotch Departments, it being necessary to reforward them to London, for revision before publication.

Notices to Correspondents.

The *Canada Medical Journal* for February last, in its Periscope Department, republishes from THE MEDICAL PRESS AND CIRCULAR a case of Biliary Vomiting by Dr. W. Koster, of Utrecht, communicated to us by Dr. W. D. Moore, of Dublin; and also a communication on the Nature and Treatment of Chilblains by H. S. Purdon, M.D., of Belfast. The source from whence these papers are selected is not even mentioned, although excerpts from other journals are acknowledged in due form. The *Canada Medical Journal* is welcome to any communication which it may think worthy of selection from our columns, and we hope it will not grudge us the credit of the communication. We are sure that the omission must have been unintentional, inasmuch as Mr. Barnard Holt's case of stricture of twelve years' duration, which appeared in our issue of January 3, is reprinted and duly acknowledged.

An Old Subscriber.—The only preparation of hypochloride of sulphur used by Mr. Milton for æne is what is now pretty generally recognized as the compound hypochloride of sulphur ointment. It consists of two drachms of the hypochloride and ten grains of carbonate of potass to an ounce of lard. Should great itching be present, a small quantity of essential oil of almonds or hydrocyanic acid may be added. It is absolutely necessary that the lard employed should be quite pure.

Onyx.—The composition of "Towle's Chlorodyne" is chloroform, ether, oil of peppermint, perchloride acid, tincture of Indian hemp, prussic acid, tincture of capsicum, morphia and treacle. The other question is one which we do not deem it consistent with Editorial etiquette to answer in our columns, but we will, if requested, communicate the information in a private note.

The Pharmaceutical Society of Great Britain.—The list has been received.

Dr. Richardson.—The letter is inserted.

Dr. Frederic Edmunds.—It is not consistent with our custom to insert letters which have been refused admission into our journals, and we must therefore decline to publish Dr. Edmunds's communication; but we have referred to the subject in our leading article.

Anticus.—The best information on the subject may be found in the volume of the "Association Medical Journal" (now *British Medical Journal*), for the year 1853.

The Royal Institution.—The notice has been received.

Mr. Griffin.—The letter and the accompanying draft petition have been received.

Mr. L. J. is thanked for his communication.

The Obstetrical Society of London.—The report has been received.

The University of Cambridge.—The notice is inserted.

WEDNESDAY, MARCH 21.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m. Prof. Huxley, "On the Classification and Structure of the Mammalia."

HUNTERIAN SOCIETY.—8 p.m. Mr. Bader, "On the Impairment of Vision in Albuminuria."

THURSDAY, MARCH 22.

ROYAL INSTITUTION.—3 p.m. Professor Frankland, "On the Non-Metallic Elements."

FRIDAY, MARCH 23.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 p.m. Prof. Huxley, "On the Classification and Structure of the Mammalia."

ROYAL INSTITUTION.—8 p.m. Dr. Benze Jones, "On the Existence in the Textures of Animals of a Fluorescent Substance closely resembling Quinine."

SATURDAY, MARCH 24.

ROYAL INSTITUTION.—3 p.m. Rev. G. Henslow, "On Structural and Systematic Botany."

MEDICAL APPOINTMENTS.

ALTHAUS, JULIUS, M.D., has been appointed Physician to the London Infirmary for Epilepsy and Paralysis, Charles-street, Portman-square. BUTT, WILLIAM F., M.R.C.S. Eng., has been promoted to Senior Resident Surgeon to the St. Pancras Workhouse and Infirmary.

BUTDS, Dr. Wm. T., has been elected House Surgeon to the Cork South Infirmary.

BELL, Prof. R., has been elected a Member of the Chemical Society. CAMPBELL, Dr. F., has been elected a Member of the Anthropological Society.

CARVER, E., M.B., F.R.C.S.E., of St. John's College, has been appointed Demonstrator of Anatomy in the University of Cambridge.

COLLIE, A., M.D., has been appointed Assistant Medical Officer to the London Fever Hospital.

DEWSON, Mr. F. S., has been appointed Resident Dispenser at the Queen's Hospital, Birmingham, vice Mr. G. Smith, resigned.

DEBURY, JOHN G., M.D. Cantab., has been appointed an additional Physician to the North London Consumption Hospital.

FOX, C. B., M.D., M.R.C.P., has been elected a Fellow of the Obstetrical Society of London.

GIBSON, F. W., M.B., has been appointed Assistant Medical Officer to the Broadnour Criminal Lunatic Asylum, near Wokingham, Berks.

GRIFF, W. J., L.R.C.P. Edin., has been elected Medical Officer to the Workhouse and Fever Hospital of the Granard Union, County Longford.

JAMIESON, W. A., M.B., has been appointed Junior House-Surgeon to the Dispensary, Preston.

MARION, E., M.R.C.S. Eng., has been elected Resident Junior Surgeon to the St. Pancras Workhouse and Infirmary.

VACANCIES.

Samaritan Free Hospital.—A physician for intern patients and two for externs, and a surgeon for extern patients.

Lincoln General Dispensary.—House-surgeon:

Carmarthen Lunatic Asylum.—Assistant Resident Medical Officer. Salary, £100 a year, with board and residence. Candidate must understand Welsh.

Trouton Hospital.—House-surgeon. Salary, £85 a year, with board, &c.

Chester General Infirmary.—House-surgeon. Salary, £80 a year, with board, &c. Assistant House-surgeon. Salary, £60, with board, &c.

Chorley Dispensary.—House-surgeon. Salary, £100, with rent and taxes.

Births, Deaths, and Marriages.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

ARSCOTT.—At Southernhay, Exeter, the wife of Robert Arscott, M.R.C.S. Eng., of a son.

CARTER.—At Budleigh, Devon, the wife of H. I. Carter, Surgeon-Major, of a daughter.

CHAMPNEYS.—At Battle, Sussex, the wife of Montagu Champneys, F.R.C.S., of a daughter.

PRALL.—At West Malling, Kent, the wife of Samuel Prall, M.D., of a daughter.

WIGNORE.—At Inverness-road, W., the wife of William Wignore, Surgeon, of a daughter.

COVEY—HEMSTED.—On March 8, at Whitechurch, Hants, Charles E. Covey, Surgeon, to Harriet, second daughter of T. R. Hemsted, Esq.

McDONOUGH—BODKIN.—On the 19th inst., in the Catholic Church, Upper Gardiner-street, by the Rev. Mr. McGee, assisted by the Rev. Sir Christopher Bellew, S.J., Francis J. McDonough, Esq., only son of Captain McDonough, J.P., Wilsnount, County Galway, to Kate, second daughter of Thomas Bodkin, Esq., M.D., F.R.C.S.I., East Court House, Traim.

PEACOCKE—SMITH.—On March 7, in All Souls' Church, Langham-place, London, by the Rev. W. Peacocke, assisted by the Rev. J. Peacocke, brothers of the bridegroom, George Peacocke, Esq., M.A., M.D., Army Medical Department, to Rose Emily Wilkison, only daughter of George Smith, Esq., Cambridge-terrace, Hyde Park, W.

RING—MILLER.—At Welsley, John Ring, M.D., to Louise, daughter of the late Reader Miller, Esq.

TAYLOR—SWANN.—On March 4, at St. Leonards-on-Sea, John Taylor, M.R.C.S., to Elizabeth, elder daughter of H. T. Swann, Esq.

MORRISON.—At Baileth Hill House, Currie, on the 14th inst., in his 87th year, Sir Alex. Morrison, Knight, M.D., Fellow of the Royal Colleges of Physicians of London and Edinburgh.

CLINICAL LECTURES ON SURGERY.

By B. WILLS RICHARDSON, F.R.C.S.I.,
SURGEON TO THE ADELAIDE HOSPITAL, DUBLIN.

(Continued from page 372, vol. xii., Second Series, MEDICAL PRESS.)

GENTLEMEN,—I wish to occupy your time this morning with a few observations regarding a couple of cases which were lately under my care in the hospital, and which I am sure those of you who studied them attentively will perfectly recollect. I shall read the particulars of each case before offering any remarks upon it.

AXILLARY KYST—TAPPED AND SUBSEQUENTLY REMOVED BY OPERATION—RECOVERY.

L. R.—, *æt.* 17, a dark-haired, dark-eyed girl, was admitted under my care into the hospital, December 18, 1863, to be treated for a tumour in the right arm-pit, which caused her much annoyance.

She attributed the origin of this swelling to a strain she experienced about eighteen months previously, while carrying a heavy box up stairs. She stated that on this occasion she felt something "give way" in the arm-pit, and that then, for the first time, she discovered a lump, the size of a filbert, which immediately became extremely tender and painful.

As regards the period she referred to as the commence

ment of the swelling, it is probable she was mistaken, and that it existed antecedent to the time she imagined it began; for, how frequently are tumours overlooked by patients—being undiscovered until they become painful from some accidental or other cause? She poulticed the tumour for many days; but, as it increased in size, she had a surgical opinion about it, and was advised to have it removed. She would not then consent to follow this advice. At last the tumour became so painful, particularly when the arm was moved, that she was compelled to relinquish work, and came into hospital for treatment.

When she was admitted in December, a tumour could be both seen and felt, under the integument of the inner wall of the right axilla, just behind the lower margin of the great pectoral muscle. It was about the size of a tolerable sized pear, and of the same shape. Three firm processes could be felt apparently extending from the tumour. One of these bands passed upwards, deep behind the clavicle; another went under the great pectoral muscle, and a third, backwards to the scapula, under which it appeared to pass. The tumour was somewhat uneven on the surface, very elastic, and afforded a distinct sense of fluctuation inferiorly, where it was thought to have a very limited adhesion to the integument. It could, however, be moved freely under the skin. A careful examination of the deep portion of the tumour, led to the opinion that this was more solid than the external part.

There were no enlarged lymphatic glands found in any part of the body.

When the arm was suddenly moved she suffered much pain, but otherwise, the tumour caused no inconvenience, except after it was handled.

There was nothing to record as to delicacy of general health, and with the exception of her local ailment, she presented no indications of illness.

From the presence of the feel of fluctuation and the movability of the tumour, I formed the opinion it was most probably of a kystic nature, and therefore punctured it on the 4th January, 1864, and gave exit to about half an ounce of a curdy puriform fluid. After the kyst was thus emptied, we were able to feel something like a nodule connected with, or forming part of, its deep wall. The next day the kyst was again full of fluid, which I discharged. The fluid, however, on this occasion was of a thin, serous nature, and slightly tinged with blood. The tumour was not then more tender than usual. This morning she was ordered to take daily a tablespoonful of the following mixture:—

\mathcal{R} . Ol. morrhue, \mathfrak{z} iiiss.
Syrup. ioidid. ferri, \mathfrak{z} ss. Misc.

\mathcal{F} t. mistura.

January 20th: The kyst has refilled with fluid and is very tense. What procedure was now to be followed with the view of relieving her of this troublesome ailment? A free opening and dressing from the bottom; injection; drainage, &c., were thought of; but we considered that time might be saved by removing the kyst altogether, which I proceeded to do on that day.

When the skin was divided and the kyst by a little dissection, isolated, we discovered three processes extending between it and the localities I have before alluded to. One of these passed under the axillary, and another, beneath the subscapular, arteries. I tied these bands with strong ligatures, and next divided them and enucleated the kyst. Two or three vessels only required the ligature. The most fluid contents of the kyst were whey-like, and its deep portion, where the induration was felt before operation, was thick and infiltrated with a cheesy material.

I had no reason to regret the operation having been performed. She had scarcely any fever after it, and her recovery would have been most rapid, only for an attack of tonsillitis which seized her on the 11th February, two days after the wound had healed.

I opened the tonsillitic abscess and she quickly convalesced.

The local treatment of the axillary wound consisted in water dressing and supporting the flaps with suitable bandaging.

(It is satisfactory to be able to report that she has had no return of diseased action in the axilla; for, we heard recently from her by letter, in which she mentioned that she continued perfectly well.)

What was the point of departure of this axillary kyst? I have named it a ganglionic purulent kyst, hence you may guess what I consider to be the probable pathological nature of the swelling. When we recollect the characters of the kystic contents, and also the cheesy infiltration of its deep wall, it appears to me to be a correct supposition, that it had its origin in an axillary lymphatic gland. Pathologists have long since recognized this starting point of purulent kysts, and you will find in the writings of Cruveilhier some interesting remarks regarding them.

According to the observation of many excellent pathologists, the lymphatic glands are often converted into tubercular kysts, or rather into kysts at the same time tubercular and purulent.

In a young phthisical person, 18 years of age, alluded to by Cruveilhier, he found most of the lymphatic glands, which are situated along the sides of the sternum replaced by as many tubercular kysts formed by a very thin but very resisting membrane, and filled by a yellowish white matter of the consistence of thick pus. There did not remain any vestige of the proper tissue of the ganglion. During life one of these kysts had opened to the right of the xyphoid appendix, so that he thought the fistulous tract might have for its point of departure or origin, caries of some rib, or cartilage. It was not so, and it turned out to be a cutaneous ganglionic fistula.

In the same subject, there likewise existed an oblong, cylindrical, tubercular kyst, which occupied the whole length of the inguinal tract. Several times during life he assured himself that this bag of pasty consistence was irreducible: it was a kyst containing grumous matter situated in front of the spermatic cord. He considered it as appertaining to an old hernial sac. Several glands behind the crural arch and along the iliac vessels were also converted into kysts containing a matter of purulent consistence. Cruveilhier has not omitted to mention that the mesenteric glands are often converted into more or less voluminous kysts, with dense fibrous walls, and that their contents are sometimes of the consistence of vitreous mastic, with or without calcareous concretions. He had also frequently observed the same alteration in the bronchial glands. These kysts are often multilocular.

With regard to the observation that lymphatic glandular kysts are at the same time purulent and tubercular, it is possible that in many of such cases the suspected tubercles are merely collections of concrete pus.

Another view may be taken of the origin of the kyst of L. R.—, although I am myself, as I have stated, inclined to attribute it to a lymphatic gland. It might, for instance, be considered that it had its beginning in an ordinary abscess which gradually became enkysted. An abscess, you may remember, is described to be a pseudo-membranous kyst, the walls of which gradually become organized and isolate the pus from the surrounding parts. According to this doctrine the kyst is formed later than the pus, and has been named by Delpech the pyogenic membrane. Cruveilhier observes that strictly speaking the distinction may be drawn between the abscess and the purulent kyst, but that the name of *kyst* should be reserved for the purulent collection of a certain age, and whose walls well organized have no manifest tendency to open outwards, and are with difficulty the seat of a new purulent secretion; and reserve the name of *abscess* for purulent collections whose walls, imperfectly organized, are constantly the seat of a purulent secretion, and have a constant tendency to open outwards.

CHRONIC ABSCESS, LIMITED TO THE INFRA-SPINOUS FOSSA, APPARENTLY HAVING ORIGINATED IN CARIES OF THE SPINE OF THE SCAPULA.—REMOVAL OF EXFOLIATIONS.—IODINE INJECTIONS.—RECOVERY.

Case 2.—M. H.—, æt. 13, a delicate looking girl, was admitted into the Hospital on the 6th of June, 1865, to be treated for a swelling over the left shoulder-blade.

So far as we could ascertain from her account, its history was as follows:—In the beginning of last April she, for the first time, felt pain in the left shoulder-blade. At that period there was no perceptible swelling. But after the pain had continued for about three weeks, tumefaction commenced, and gradually increased until a tumour was formed of the proportions it had when she was admitted.

She thought that after the swelling appeared she began to lose flesh, and about a week before her admission she commenced to perspire more than natural.

She had not any rigors since the swelling formed; and she was free from cough.

Her appearance and symptoms, on admission were as follows:—Complexion delicate; pulse, 112; tongue clean and moist; bowels regular; appetite good.

Corresponding exactly to the whole of the infra-spinous fossa of the left scapula, and having the contour of that space, as represented in this illustration by Mr. Oldham, there was a tolerably elevated, but flattened, fluctuating tumour, having its superjacent integument slightly discolored from previous applications of tincture of iodine. It was somewhat painful in its centre, and its temperature, if any thing, was a little higher than that over the right infra-spinous fossa.

The margin of the swelling gave to the finger a sensation of thickening, and this was most decided and distinct in the situation of the scapular spine, where also there was tenderness when pressed.

There was little doubt, from the local symptoms, that the swelling was an abscess, and that most probably it had its origin in disease of the spine of the scapula. I determined, therefore, to empty the abscess by means of M. Chassaignac's drainage trochar and tubing, and to make the upper opening near the spine of the scapula, to facilitate the exploration of the state of that process, and the removal of exfoliations, if necessary to do so.

June 10th: I drew through the abscess a piece of ordinary perforated drainage tubing, by means of Chassaignac's trochar, having a notch a short distance behind the point for catching the tube. In fig. 3 the trochar is re-

presented in the abscess, the tube being attached near the point ready for drawing through the abscess.

After the tube was passed, both its ends were tied together, which secured it from slipping out of the abscess. The matter of the abscess was thin, not whey-like. It flowed freely through the tube. She was ordered wine in addition to her full diet.

11th to 13th: The abscess discharged freely through the tube, and she was free from constitutional disturbance. To take half an ounce of the following mixture three times daily:—

R. Sulph. quinae, grs. xvi.
ferri, grs. xx.
Acid. sulph. dil., ℥i.
Syrup. flor. aurant. ℥ss.
Aque ad. ℥viii. Misc.

Ft. mistura.

15th: The tube having become obstructed, I directed Mr. Maxwell Reilly, our resident pupil, to pass a stream of tepid water through it, by which some shreddy pus was brought away.

16th: Discharge very trifling and whey-like in appearance. The abscess was again washed out this morning. Scarcely any discharge.

23rd: I removed the tube, having previously fastened a string to one end of it, for facility of reintroduction, if necessary. The cavity was found to be much diminished in size. A probe having been passed through the upper opening to the spine of scapula, this process was found, as anticipated, to be extensively denuded, rough and manifestly exfoliating.

The floor of the infra-spinous fossa did not afford any evidence of being stripped of its periosteum. I threw some tepid water into the abscess, and a few purulent flocculi were thereby brought away. Tube replaced.

27th: I removed the tube to-day, as I fancied it might be acting the part of a seton.

Continued taking the iron and quinine mixture.

30th: Discharge again lessening.

Notwithstanding the nearness of the upper opening to the diseased bone, it has diminished much in size, whereas the lower one has rather increased, probably in consequence of the gravitation of the discharge towards the latter for facility of escape. Spine of scapula felt as it did when last examined. Loose bone could not yet be detected.

June 9th: Calibre of abscess about the same. Injected it that day with the following iodated solution with the view of facilitating exfoliation:—

R. Tinct. iodinii, ℥i.

Aque destillat. ad. ℥viii. Misc.

Ft. injectio.

11th: No unpleasant result after the injection. Repeated it.

12th: Scarcely any discharge since the injection of yesterday.

13th: Discharge increasing. I injected the abscess again this day. Two minutes after doing so, I tested the urine for iodine with the starch and nitric acid test. The result was negative. Tested another specimen passed in ten minutes after the injection, when a light violet-coloured iodide of starch was formed. She had not partaken of any food for five hours previous to these experiments.

14th: Abscess discharging a more laudable pus. Exfoliation of a portion of spine of scapula progressing. I injected the iodine solution again this day, the patient being at the time, four hours without food. In four minutes afterwards I tested the urine for iodine, but failed to detect it. Tested again in nine minutes after the injection, and found the iodine reaction most characteristic.

21st: The abscess was evidently much smaller, as it now held considerably less fluid than heretofore. I injected it with iodine this morning, and tested the urine in five minutes afterwards. The iodine reaction was most decided. She breakfasted four hours previous to the injecting. In five hours after the injection the urine gave a very dark violet reaction to the starch test for iodine. Ordered half an ounce of cod-liver oil three times daily.

August 3rd: Exfoliation of scapular spine looser than when last examined.

10th: Enlarged the upper opening, and removed a large exfoliation from the spine of the scapula.

17th: Abscess has contracted into two fistulae which discharge but little pus. The skin is becoming puckered at the seat of the upper opening. She was now so much improved in general health that I allowed her to return home.

March 24, 1865: She visited the hospital to-day. The site of the abscess is perfectly consolidated, and, with the exception of a little integumental puckering where the exfoliation was removed, and a very small cicatrix at the seat of the lower opening, there is no other evidence of morbid action having occurred in the infra-spinous fossa.

It is scarcely necessary to remind you that the instrument above figured, is not absolutely necessary for introducing the tube; indeed, Chassaignae himself states, that it may be conducted through an abscess by means of a stylet carrying a thread to which the tube is attached. An opening having been made into the most depending portion of the abscess, the stylet is there introduced, passed on to where we wish it to emerge. At this spot the skin is to be raised with the point of the stylet; on the raised spot an incision is made, which allows the stylet to pass out.

Chassaignae recommends the drainage treatment in a large variety of affections. Thus, he has treated by this method—Diffused abscess under the scalp; peri-articular phlegmon of the hip; suppurating arthritis of the knee; urinary fistula; abscess of the iliac fossa; abscess of the lower jaw; deep abscess of the metacarpal region; suppuration of trochanteric bursa; large bloody effusion under the calf, the result of accident; abscess of the calf; suppuration behind the ear; abscess in the groin; hygroma of the knee; abscess of stump after amputation; abscess in iliac fossa; syphilitic tumour of tibia; necrosis of lower jaw; hydrocele.

You will find the drainage tube an excellent tent for placing in an acute abscess after opening it. Before the perforated tube was introduced into surgery, plugs of lint or pieces of prepared sponge were usually placed in the opening, which had the effect of confining the matter, unless ulceration enlarged the opening. A piece of drainage tube passed into the abscess not only keeps the opening patent, but also allows matter to pass through it almost as fast as it is formed.

You saw how well it did this duty in two cases.

lital abscess which were recently in our wards, in both of which cases I inserted a piece of tube instead of a tent of lint. As Chassaignac truly remarks, the ordinary plug in the treatment of acute abscess has often quite a contrary effect to that for which it was intended, being a veritable obturator of purulent orifices.

M. Chassaignac seems to think that the drainage trochar only separates our tissues and does not cut them. I hardly think he will get many to accede to this opinion. When we recollect the number of cutting edges to its sharp end and the minuteness and intimate connexion of the component structures of the punctured part, it is difficult to comprehend how they could escape cutting or laceration.

In the white tumour of the knee in Chassaignac's list of cases treated by drainage, not only was tincture of iodine thrown into the joint, but likewise the articulation was frequently washed out.

In the case of M. H.— I did not think it necessary to introduce the tube *par adossement*, as Chassaignac calls it, having resolved to remove the carious bone as soon as I possibly could do so. He considers it the best way of treating caries and necrosis. It is carried out as follows:— The tube is passed to, and so as to touch, if possible, the diseased bone, then the end being brought out at a certain distance from this point, the bent portion of the tube forms a tangent with the diseased osseous structure.

In addition to the diseases above enumerated as having been treated by Chassaignac after the drainage method, he also mentions he has used it in fistula lacrymalis, ranula, ascites, and pleuritic effusions, including empyema. Some persons might hold that the drainage tube is merely a seton, to which Chassaignac would reply, that it is a conducting tube for leading outwards the fluids with which it is in contact. After all, is not a seton tape a solid conductor of the fluids, as soon as the opening made for it enlarges? Indeed, the opening for the tube will also do so, and then the tube is not only a hollow, but likewise acts the part of a solid conductor. Be this as it may, I believe the tube to be an excellent auxiliary in the treatment of many collections of fluid; but it should be carefully watched, and if you suspect it to be maintaining the discharge you had better remove it.

In my experiments with the view of ascertaining how soon the iodine would appear in the urine after the abscess was injected with the iodated solution, I did not detect the iodine sooner than five minutes after the injection:—

Thus the urine was tested in two minutes after the injection	Result negative.
In ten minutes	
Do. do.	Iodine detected.
In four minutes	
Do. do.	Result negative.
In nine minutes	
Do. do.	Iodine reaction well marked.
In five minutes	Do. do.
In five hours	Urine turned almost black with iodine tests.

In the *London Medical Gazette* there are some interesting remarks and experiments recorded by Mr. Erichsen, connected with this subject. In Mayer's experiment, alluded to by Mr. Erichsen, a solution of ferro-prussiate of potash was injected into the lungs, and was detected in the urine in eight minutes.

Westrumb's experiment was more precise, because he took the precaution of obtaining the urine immediately after it entered the ureters. Having divided the ureters, and fixed tubes in them, and having obtained the urine as it flowed, he found the ferro-prussiate in the urine in two minutes after it was introduced into the stomach. Itchberger, on the other hand, who experimented upon a boy with ectopia vesicæ, did not find the ferro-prussiate in the urine until an hour after it was swallowed.

Mr. Erichsen experimented upon a boy similarly malformed as Itchberger's boy. The substances he selected for his experiments were—prussiate of potash; infusion of galls; of rhubarb; of madder; of uva ursi, and of log-wood. The citrates of soda and potash; the tartrate of soda, and the acetate of potash.

As in Itchberger's case, the stomach was the medium by which the substances were introduced into the system. In these experiments the earliest period the prussiate of potash appeared in the urine was one minute, and the longest time that elapsed before its presence was revealed, was thirty minutes, this great difference in the rapidity of absorption by the stomach, Mr. Erichsen thought, seemed to depend upon the condition of the digestive process at the time the experiments were performed; being slow when the stomach was full, and more rapid when it was empty.

Erichsen's next experiments were made with the vegetable infusions; but, the condition of the stomach being as far as possible the same as it was with the prussiate of potash experiments, he found that they took a much longer period to appear in the urine than in them. The earliest period at which it could be detected in the urine being sixteen minutes, and the latest thirty-six minutes. He now endeavoured to ascertain how soon the urine, acid at the time of each experiment, would become alkaline, after the administration of some of the salts of the fixed alkalis. In one of these cases, twenty-eight minutes were required for the urine to become alkaline; in another forty-seven minutes elapsed before the alkaline reaction was evident; and, in two other instances thirty-four and forty minutes respectively elapsed. Although the experiments I tried were not analogous to any of those alluded to, as in one case the fluid was injected into the substance of the lung, and in the others, the absorbing surface of the stomach was selected for the experiments, yet it is interesting to observe that the iodine was detected in the urine in five minutes after the abscess was injected with a weak solution of that substance. Indeed, the iodine reaction was so well marked on that occasion, it is probable the iodine would have been detected sooner had it been looked for.

Some of you may ask why the experiments were performed while the girl fasted, as the stomach was not selected for introducing the iodine into the system? It is well known that an over-distended state of the veins interferes very much with their absorbing functions, and therefore it was thought advisable she should not take breakfast until each experiment was concluded.

In none of my experiments, as I have stated, did I detect the iodine in the urine sooner than five minutes, but it was mentioned by Dr. Maurice Collis, at a meeting of the Surgical Society in the Session of 1864-5, that Professor Macnamara tested the urine after he had injected the tunica vaginalis with tincture of iodine, and detected that substance, Dr. Collis having with his watch timed the experiment, in forty seconds. Now, allowing a few seconds, say ten, for the passage of the urine into the bladder and through the urethra, the iodine must have passed through the kidneys in about thirty seconds, just half the time the ferro-cyanide took to reach the orifices of the ureters in the shortest of Erichsen's experiments!

From what I have just stated, it must appear to you, that in deciding a question of this kind, more accuracy is insured by obtaining the urine direct from the ureters than from the urethra, owing to the delay attendant upon the process of micturition.

THE CHARTERHOUSE.—Mr. C. R. Nicoll, Battalion Surgeon of the Grenadier Guards, has been elected medical officer of the charterhouse. There were originally eighteen candidates, one of whom did not go to the poll. Amongst them were two army surgeons, one retired militia surgeon, one or two physicians, and the rest were general practitioners. The appointment has for many years been considered the great prize for the general practitioners,

Hospital Reports.

MATER MISERICORDIE HOSPITAL.

REMARKABLE CASE OF THORACIC ANEURISM.

(Under the care of Dr. HAYDEN.)

Reported by Dr. BELCHER.

I AM indebted to Dr. Hayden, not only for the complete manner in which he exhibited to me the chief features of interest in the following case at the time of my visit, but also for his kindness in placing at my disposal his case-book, from which I have compiled the following record, mostly in his own words:—

W. R., aged 33, a native of Carrick-on-Suir, admitted 12th February, 1866, at the request of Dr. Fitzgerald. The patient is by occupation a cab-driver; has been a hard drinker, though he is a hale-looking man. He is married, the father of three children, and up to the occurrence of this attack, his health has been generally good. About two years ago he was knocked down by his own cab while under the influence of drink, and received a blow on the back. Subsequently he enjoyed apparently good health until about three months since, when he began to suffer from pain in his chest. This pain was at first of a *knitting* character, but afterwards felt as if shooting thence to the back, and down the right arm. About six months since he, for the first time, observed a swelling in front of the chest on the right side, and about the same time he became troubled with "beating" in that situation.

When the pain first attacked him, he was in the habit of relieving himself by forcibly extending his back. He never spat blood, nor has he at any time experienced difficulty in swallowing, or loss of voice, or even hoarseness. The pain which he now suffers is so excruciating on the right side of the chest as to deprive him of sleep. His appetite is bad; his bowels are confined; his pulse, which ranges from 84 to 96, is regular and of moderate volume, but is slightly dicrotous, while it is equal on both sides. The pupils are of normal size and equal.

On the right side of the chest, anteriorly, is a semi-globular prominence about an inch and a-half in advance of the level of the left side. It is about three inches in vertical and also in transverse diameter, and extends from half an inch below the clavicle to the nipple, and from the right margin of the sternum about three inches outwards. The hand placed on this tumour, however lightly, causes pain, and experiences a double shock; the first strong and coincident with the cardiac impulse, or a little posterior in time to it; the second disturbing or elevating the tumour less, and, apparently, a back stroke received by the wall of the sac in the act of recoiling. Over this tumour a double sound is heard.

Both sounds are remarkably clear and synchronous with those of the heart, but entirely *without murmur*. The shock is felt more strongly over the outer than over the inner portion of the tumour, and is diastolic. From the clavicle for four inches downwards, there is complete dulness and total absence of respiratory sound. The same condition prevails to an equal extent transversely from the right margin of the sternum.

Elsewhere over the right side percussion and respiration are normal, as likewise over the entire of the left side. The apex beat of the heart is discernible in the sixth intercostal space, and half an inch externally to the nipple, or rather to a perpendicular line from the nipple; and from the apex point outwards, for about three inches in the sixth intercostal space, a pulsation is likewise observed synchronous with the cardiac impulse.

Over the seat of this, however, percussion yields a clear sound. There is no increase in the area of precordial dulness, nor cardiac fremitus. The first sound, as heard over the apex, is somewhat soft and prolonged, but there is no

distinct murmur attending it in this situation. Over the base, however—*i. e.*, to the inside of the nipple—a sharp "whiffling" murmur is heard accompanying the first sound. This murmur is loudest over the pulmonary artery—*i. e.*, over the second left costal cartilage, at its junction with the sternum; and is, moreover, universally diffused over the left side anteriorly.

This murmur, wherever heard, is audible only during the latter part of expiration and the first part of inspiration—*i. e.*, when the lung is only partly distended with air. It is not heard at the acme of inspiration, nor for a brief period before and after this. The murmur is not transmitted in the course of the aorta; nor is it heard to the right of the mesial line of the sternum. Posteriorly the resonance is universal, and equal on both sides. Respiration is likewise normal, but a little louder on the left side than on the right, while over both sides a double sound is heard. This sound is synchronous with the sounds of the heart and of the tumour, and is unattended with murmur. Impulse is not perceptible behind; nor is there local tenderness in any direction on pressure.

March 10.—Since last report the tumour has advanced, inclining slightly to the right. It is now rather conical, and at least two inches in advance of the corresponding part of the left side. It is *soft* and *yielding* all over, with the exception of a very small portion next the sternum. Manifestly, the ribs and costal cartilages have been entirely eroded over the greater portion of it. The double pulsation and sound are remarkably strong and loud over the tumour. There is visible pulsation of the carotids, and there is a double sound, but no murmur, audible in these vessels.

The act of placing the patient on his back with his head on the same level with the trunk does not in any degree modify the sounds or pulsations in the tumour.

Since last report the patient has occasionally suffered from pain over the tumour, in the right scapular region and in the right shoulder, extending down along the inner side of the arm as far as the elbow. These pains somewhat varied in situation, and were frequently so urgent as to deprive the patient of sleep, having been usually most severe at night. They were, however, invariably and effectually removed by the application of two leeches to the affected part, followed by a warm poultice. No leech has, however, been applied to the tumour itself, but in its vicinity, owing to the proximity of the sac to the cutaneous surface. The patient has been taking, twice daily, a draught containing 40 minims of the liquor morphiae hydrochloratis, and a tablespoonful thrice daily of a mixture consisting of tincture of the perchloride of iron and chloric ether, of each three drachms, in eight ounces of infusion of quassia. Enemata and castor oil draughts were given to keep the bowels free. He has been taking strong beef-tea and meat, with as little fluid as was found sufficient to allay his thirst, which was urgent. The pulse has varied from 78 to 96; is regular and equal on both sides. The pupils are normal and equal. He complains of no dysphagia or dyspnoea, even in the recumbent position. The patient lies almost constantly on the right side, and it was probably owing to this cause that slight œdema appeared some weeks ago in the right axillary region, but it disappeared in the course of a few days, and has not returned.

Pressure with the stethoscope over the abdominal aorta, or the femoral artery, readily gives rise to a loud arterial murmur, but there is no murmur in these, or in other vessels, in the absence of pressure. The appetite, sleep, and general health of the patient are good.

March 14th: He now experiences much pain in the tumour, which is manifestly increasing forwards and likewise outwards towards the right axilla. He also feels pain in the right scapular region. In this latter situation the application of two leeches relieved him. There is slight œdema in the axilla, and down the arm, in which situation, also, in the forearm, much pain is complained of. Pulse 96, with bounding action in the tumour. Stop the

iron, and instead give ten drops of tincture of digitalis every fourth hour; also an enema.

March 15th: The bowels have been freed by the enema. The two leeches applied in the axilla and the tincture of digitalis completely removed the pain. Much swelling is now observable in the axilla and arm.

March 19th (the date of my visit): For the last few days he has suffered much pain and has perspired copiously whilst sleeping. There is much œdema over the right side, from the axilla to the crest of the ileum; the breathing is embarrassed when he sits up, and to-day, for the first time, he notices some difficulty in swallowing. The greater portion of the anterior wall of the right side of the chest, above the nipple, is now raised about two inches somewhat uniformly, not as before in a limited space and conically. Continue morphia draughts twice daily; each draught to contain forty minims of the liquor morphiæ hydrochloratis to an ounce of water.

22nd: For the last three days the systolic bruit has ceased to be heard over the left side, and, coincidentally, the tumour has pulsated less distinctly; it is likewise firmer to the touch. Yesterday he frequently took $\mathfrak{m}i.$ of creosote in a table-spoonful of water to relieve thirst, with good effect. Pulse 96.

23rd: Pulse 96, rather weak, but regular; much swelling in the left supra-clavicular fossa, where cervical vessels are felt and heard to pulsate. He complains of much difficulty in breathing; the right side of the chest is comparatively dull, posteriorly and inferiorly, where, likewise, respiration is rather feeble and bronchial in character. On both sides posteriorly a double sound and a single impulse is perceived, louder and stronger on the left. $\mathfrak{z}iss.$ vin. ipecac. , to be added to digitalis mixture.

Proceedings of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY OF LONDON.

MARCH 1ST, 1866.

Dr. ALDERSON, F.R.S., President.

ANNIVERSARY MEETING.

THE PRESIDENT declared the ballot for the election of officers and members of Council for 1866-7 open for one hour, and nominated Dr. Markham and Mr. G. Gaskoin, scrutineers.

The Auditors' report was then read.

Dr. WEBSTER moved the adoption of the Auditors' report. He said the financial condition of the Society was most satisfactory, and remarked on the minuteness with which the accounts were kept. There was an item of 8s. for fines, and one of 10s. 6d. for old brass. Dr. Webster spoke with approval of the fact that half the expenditure for books was for foreign books.

Mr. PARTRIDGE seconded the motion.

Dr. PITMAN said that Dr. Webster had probably forgotten that comparatively little was spent on English books because (from the liberality of authors) many were presented to the Society.

The Report of Council was then read. After congratulating the Society on its prosperity, and on the unusually large number of Fellows elected, the Report gave an account of the present number of Fellows, stating changes by death, elections, and resignations. The financial condition of the Society appears to be very satisfactory. The Society has funded £500, and has carried £190 to the next year's account. The sum now standing in the names of trustees is £4816 11s. 5d. There have been large additions to the library—350 books, exclusive of continuations—182 presented, 168 purchased; 191 of these were English, 159 foreign. Dr. Ashburner had given 61 volumes on the early and later history of Mesmerism. Mr. Curling,

who, to quote the words of the Report, has repeatedly laid the Society under similar obligations, had presented a rare and beautiful medallion executed in ware in 1788 of Dr. Joseph Black, the Professor of Chemistry in the University of Edinburgh. The thanks of the Society were also due to Sir Rutherford Alcock for a portrait of his father—an oil painting by Haydon—and for an oil painting by Mr. Inskipp, a portrait of Sir Rutherford himself. After speaking of special additions to the library, the Report says:—"The librarians, however, report with regret, and in the hope that this notice may attract the attention of the Fellows, that very few additions have been made to the Society's collection of photographic portraits of its Fellows, and to the photographs of pathological specimens." Two committees had been appointed,—one to report on the subject of "Hypodermic Injections," and the other on "Electricity in the Treatment of Disease."

The result of the ballot for officers and members of Council was then announced by the President:—President: James Alderson, M.D., F.R.S. Vice-Presidents: *Patrick Black, M.D.; *Henry Beece Jones, M.D., F.R.S.; *Prescott Gardner Hewett; *Charles Hewitt Moore. Treasurers: Henry Alfred Pitman, M.D.; *George Busk, F.R.S. Secretaries: *Henry Hyde Salter, M.D., F.R.S.; *George Green Gascoven. Librarians: Alexander Patrick Stewart, M.D.; *Charles Brooke, F.R.S. Other Members of Council: Andrew Whyte Barclay, M.D.; Edmund Lloyd Birkett, M.D.; *John Clarke, M.D.; *Patrick Fraser, M.D.; *Richard Quain, M.D.; *James Dixon; *Edwin Humby; *John Abernethy Kingdon; *John Marshall, F.R.S.; Alfred Poland. Those gentlemen to whose names asterisks are prefixed were not on the Council, or did not fill the same office, last year.

Mr. CHARLES HAWKINS moved the adoption of the Report. He said that, unlike Dr. Webster, he was not enamoured of large balances, and did not think that the present members of the Society should save money for people who came after them. After taking away the sum received for letting lodgings, there was a balance of five hundred pounds for books. He thought more ought to be laid out on English books, and he added the Society was quite rich enough to buy them. He thought the library ought to be not simply a medical library, but that it should also contain books on science, and books bordering on scientific subjects. Again, he could see no reason why the present members should remain stewing in that room in order that those who came after might find a large balance. In latter years, Mr. Hawkins said, the Anniversary Meeting had been held in the evening; he thought it would be better to hold them, as they used to be held, in the afternoon. It was only fair to do this, in order to ensure a proper attendance as a compliment to the President.

Dr. FRAZER, in seconding the resolution, said that he quite agreed with Mr. Hawkins that the Society was rich enough to buy English books, and ought not to depend on the generosity of authors.

The PRESIDENT remarked that the observations of the speakers would be borne in mind by the Council. He added that a small balance would prevent the Society from ever leaving its present room, as the sum asked for a larger place was much greater than their present balance.

Dr. PITMAN then moved the alteration of one of the bye-laws, the resolution being "That the words Fellows, Members, and Licentiates be inserted in the place of the words Fellows and Members." The law, as it stood, excluded Licentiates, and the object of the resolution was to enable them to be proposed as members.

The resolution was seconded by Dr. BARNES.

Mr. PARTRIDGE asked if the rule thus altered would not include these who might be licentiates in special branches only, as for instance licentiates in Dental Surgery, Midwifery, &c.

Dr. PITMAN said it was not contemplated to include those who were licentiates in special branches merely.

Dr. SANKEY asked if Masters in Surgery were included?

Mr. CHARLES HAWKINS thought such an alteration ought to have been brought forward by the Council, and that the law should be so worded as to include all legally qualified medical men. He remarked, too, that he thought the rule limiting the number of general practitioners to one-third should be abrogated. He thought any one on the Register should be allowed to be a candidate.

Mr. PARTIDGE would second Mr. Hawkins' proposal.

Dr. PITMAN said that many medical men did not think it worth while to register, and that there were many Fellows of the College of Physicians whose names were not registered. Mr. Hawkins' proposal, therefore, would exclude some properly qualified candidates.

Mr. HAWKINS meant to say that any one, either properly qualified or registered under the Act, should be eligible. He thought, however, that Dr. Pitman's motion might be taken as a step.

Dr. Pitman's motion was then carried.

THE PRESIDENT'S ADDRESS.

The PRESIDENT said he had first to fulfil the melancholy duty of speaking of the Fellows who had died during the past year. He selected the more prominent characters and grouped them, so as not only to bring forward their merits, but to deduce lessons from their career which might be useful to the living. He mentioned especially Dr. Ferguson, Physician Extraordinary to the Queen, his extensive practice and his general accomplishments, which made him welcome in the best society. Somewhat as an antithesis, he mentioned Dr. King, of Eltham, who was also a highly successful practitioner, and who was the object of the deepest attachment, and was satisfied with no more brilliant reward. Among the honorary Fellows he particularly mentioned Mr. William Hooker and the greatly lamented Mr. Brande, and concluded his notice of the departed by referring to the obituary, paying a tribute to those whose less prominent career may not have less useful and less happy and their loss not less deeply regretted. He then referred to the Congress to be held at Constantinople to inquire into the circumstances connected with the introduction of cholera into Europe, and trusted that the investigation might throw some light on the epizootic now present, and proceeded as follows:—"Many will be sorry to observe how this visitation is being treated under a sort of panic by the Legislature, with less regard than might have been desirable to the amount of knowledge which we already possess, or to the sensible deductions thence to be derived. I have no doubt that you, the members of this Society, are too enlightened to fall into the peculiar notions adopted by the general public about this cattle disease, or plague, as they are pleased to call it; that you all perceive the futility of hunting for specifics, of trying to identify it with diseases of the human constitution, and of believing in its importation and propagation by contagion as the only cause. All these fallacious views seem to blind the Legislature as well as the public to facts which are clearly established. These facts are, that the cattle disease, like cholera, follows a certain course, which is undeviating in its direction, though the visitation skips over some localities; that the disease also, like cholera or any other epidemic, abides only for a certain period in each locality, and that it is most virulent and unmanageable at the beginning of each outbreak, and becomes amenable to simple treatment, or any treatment not positively injurious, towards the end of its presence in each place, whilst the ultimate cause of the disease and the law of its progress are unknown to us. All these facts display the fallacy of pretending to stop or exterminate—that is, in the presumptuous phraseology of the day, 'to stamp out' the disease by means of preventing contact; and the same facts testify to the sad want of judgment in sacrificing stock, and adding inconvenience to the farmers' loss, in order to obtain an end, which, according to the knowledge which we possess, is obviously impossible. None will, of course, deny that there is a certain amount

of power to communicate the disease by what is termed contagion or infection, and that moderate precautions to avoid needless contact are wise and good; but it is plain that when the best is done in this direction the laws of transmission and duration will defy all Orders in Council and all Parliamentary enactments either to obtain immunity or to effect 'stamping out.' It is strange that certain French journals should have boasted of their immunity from cattle disease as a merit, and have even taunted us that, while they are spared, we owe it to our ignorance; whereas they might perceive as well as we do that the course of the visitation is no more to be arrested than the course of a cyclone or that of any other atmospheric phenomena; and we might, if we chose, respond to the rebuke by observing that France has been spared the murrain whilst they have had the cholera." The President then congratulated the Society on the success of the past session, and on the character of the communications as well as of the discussions which followed—discussions which had been conducted with the utmost amenity as well as advantage to medical knowledge. He expressed a hope that more papers would be introduced on scientific subjects collateral to medicine, and hinted that many of those which were laid before the Royal Society would find a more appreciating audience in the Society he was addressing. He concluded by referring to the committees established in 1862, and on the valuable matter contained in the Reports of these of 1862 and 1861. He did not doubt that the two now sitting would be equally successful; that the records of these committees would prove enduring memorials of the Society's vitality. He congratulated himself on having the honour of being President of a Society which is animated with the true spirit of inquiry, and follows out its object with willing and united feeling.

Mr. CURLING moved a vote of thanks to the President for his able address, with a request that it should be printed. To one point Mr. Curling said he might be permitted to refer. The President had spoken of the reputation of the late Mr. James of Exeter. For his (Mr. Curling's) part he should have pointed out the present Mr. James, the father of the Mr. James lately deceased, as the surgeon whose reputation had made the name James famous.

Mr. C. H. MOORE cordially seconded Mr. Curling's motion. He remarked on the genial personal influence of the President in the Council as well as in the Society.

Mr. BROOKE proposed and Dr. GIBB seconded, a vote of thanks to the retiring Hon. Secretaries—Dr. Fuller and Mr. Birkett.

Dr. FULLER said the work had been a labour of love; they had both endeavoured to do their duty. He was pleased to be able to refer to the flourishing state of the Society. In leaving his office he wished to bear testimony to the very valuable services of the Sub-Librarian. It would, Dr. Fuller said, be very difficult for the Secretaries to get through their work were it not for the efficient aid of Mr. Wheatley.

Mr. BIRKETT had had great pleasure in performing the duties of the post he was about to leave. There was one point on which he would take the opportunity of commenting. He thought a little change was required in the manner of conducting the meetings of the Society. He thought it would be well to hold exhibitions of instruments. This would encourage instrument makers to send instruments.

A NEW Institution called the London Infirmary for Epilepsy and Paralysis, has been opened at No. 19, Charles-street, Portman-square, W. The president is Lord Wharncliffe. The vice-presidents and committee include some well-known philanthropic names, and the services of Alexander Ure, F.R.C.S., have been secured as Consulting-Surgeon, and of Dr. Julius Althaus, as Physician. "Confirmed cases of epilepsy and paralysis," says the prospectus, "are excluded on principle from the general Hospitals, as causing a great deal of trouble, and expending in vain the funds of those charities."

SURGICAL SOCIETY OF IRELAND.

Professor HARGRAVE in the Chair.

COMPLICATED RESULTS OF SEVERE EXTERNAL INJURY—
LIFE PROLONGED FOR TWELVE HOURS—APPEARANCES
ON DISSECTION—WITH REMARKS.

By Dr. GEOGHEGAN,

SURGEON TO THE CITY OF DUBLIN HOSPITAL.

AN elderly man was crushed by the fall of a mass of masonry. He was brought to hospital in a state of collapse, and lived twelve hours. Previously to death there was some, but not considerable, difficulty of breathing. Throughout there was much thirst, which was freely indulged.

The following injuries had been sustained:—A compound fracture of the left ulna, about one and a half inches below the olecranon, with a large wound on the inner aspect of the forearm, communicating with the front of the elbow-joint. The superior fragment of the ulna was displaced considerably backwards. 2nd. Comminuted fracture of the lower end of the left femur. 3rd. Fracture of fifth and sixth ribs of same side. 4th. A small and shallow rent of the right lobe of the liver on its superior aspect. The torn surface was granular and slightly smeared with blood. The organ was in an early stage of cirrhosis. Blood had been effused in moderate quantity in the retro-peritoneal cellular structure, investing the ascending colon and right kidney. 5th. There was a somewhat ragged rent, about two inches long, in the posterior part of the left fleshy expansion of the diaphragm, on the thoracic aspect of which a thin stratum of blood was effused between the serous and muscular layers. Through the rupture, the stomach and about eighteen inches of the transverse and descending colon had passed into the cavity of the left pleura, pushing the left lung forwards and to the right side. The stomach (enormously distended with mixed solids and liquids) lay across the cavity, completely rotated on its transverse axis, so that its great curvature presented upwards embraced by the protruded colon. Owing to the above disposition of parts, the lower portion of the œsophagus was necessarily abruptly doubled on itself at a very acute angle. The left lung was normal, the right rather congested. The heart cavities were empty; the organ healthy.

When the stomach was opened some days after death, its lining membrane afforded an excellent example of the dark blackish-brown staining and softening which result from the imbibition of the acids of digestion by a surface whose minute vessels had been previously injected with blood; a condition which occasionally simulates in no slight degree, even to the experienced eye, the effects of the sulphuric and oxalic acids, and which I have known in one instance to have apparently masked pre-existing inflammatory appearances resulting from a criminal administration of arsenic.

Whilst experience attests the remarkable fact that lacerations and gunshot wounds of the diaphragm, even with protrusion of the stomach and colon into the left chest, are compatible either with the maintenance of life for long and indefinite periods, or even with final recovery, the present example is, notwithstanding, of interest from the circumstance that existence was prolonged even for twelve hours, notwithstanding a long and formidable array of accompanying lesions, both internal and external.

The unimpaired facility of swallowing which existed under the altered conditions of the œsophagus and the inverted state of the stomach, together with absence of vomiting, are also worthy of attention. The locality of the rupture deviated from that assigned as the usual one by Devergie*—namely, the tendinous centre where it adjoins the left muscular expansion.

* *Medicine legale.*

CANCER OF THE PENIS.

Dr. GEOGHEGAN presented a well-marked example of cancer of the penis.

The subject was a rather healthy fresh-coloured man 50 years of age, who had laboured under the disease for four months.

No hereditary taint was traceable. The malady had commenced as a superficial sore at the left side of the glans, from whence it spread considerably along the urethral aspect and towards the frænum, leaving the corpora cavernosa untouched. There was considerable discharge of a thick yellowish-brown inodorous pus, untinged at any time with blood. The disease has been unattended by pain throughout. There was no phymosis, although latterly, owing to the slightly increased bulk and induration of the diseased mass, retraction of the prepuce was difficult. The sore on the glans was of a healthy red colour, the granulations large, and the margin of the ulcer formed a flattened indurated ring. The urethral portion of the ulceration and the glans generally were of the consistence of cartilage; the orifice of the urethra was narrowed, and surrounded by an hardened rim.

The inguinal glands of both groins were perhaps slightly enlarged—those at the pubic end of the right inguinal range more distinctly so.*

Although the prospect in amputation of the penis for cancer is but little encouraging on the whole, no alternative besides removal presented itself.

The troublesome hæmorrhage, both primary and consecutive, which sometimes attends on the operation, induced me to employ the chain ecraseur, the integuments having been previously divided by a circular incision about an inch and a half in front of the scrotum. Chloroform was employed. Although the instrument was very slowly worked, still, on removal, the dorsal arteries sprang as if they had been divided with the knife, and were at once ligatured. Those of the corpora cavernosa and that of the septum did not bleed, although there was a slight diffuse weeping from the divided surface of the first-named bodies. The urethra was slit up for three quarters of an inch, and the retracted angles attached by points of suture to the neighbouring integuments. The section of the separated portion of the member appeared quite sharp, that of the stump a little irregular. The case has since progressed most favourably, but with a single and trivial consecutive bleeding. The patient, however, as commonly occurs in such cases, was for some time rather desponding. The stream of urine (now a month since the operation) is ample, and discharged in an arch. A full-sized bougie is daily introduced by the patient, and the wound has quite healed.

A section of the removed mass showed that the disease had pervaded almost the entire thickness of the glans. Its surface was greyish-white and non-vascular. Typical nucleated and caudate cells of schirrhoid cancer, with large eccentric nuclei and with nucleoli, were clearly visible on a microscopic examination kindly made by Mr. Cunningham, L.R.C.S.

COMPLICATED HEMATOCELE—PECULIAR CHARACTER OF THE CONTENTS, ETC.

Dr. GEOGHEGAN exhibited a well-marked specimen of hematocele, presenting some peculiarities of interest.

The subject, a man above 70 years of age, and generally healthy, had laboured for many years under hematocele at the right side. More lately he became the subject of double inguinal hernia, and when admitted into hospital was suffering from retention of urine, the result of enlarged prostate. The hematocele had attained the volume of a good-sized melon, and the penis was absorbed into the

* As these latter continued enlarged, and were moreover indurated, I removed them by incision about three weeks after the operation on the penis. One of them, deeply seated, proved to be of the size of a small walnut. Cancer cells were distinctly visible under the microscope.

general bulk of the swelling, the preputial orifice presenting, on its front, as an elevated ring. The tumour was nearly spherical, opaque, painless, tense, and distinctly fluctuating; the cord was free, and the hernia above it readily reducible. As a good deal of difficulty had been encountered in manoeuvring the catheter through the pendulous portion of the urethra, owing to the pressure of the swelling, it was determined to attempt the diminution of the bulk of the latter by tapping. Accordingly, about six ounces of bloody fluid (sp. gr. 1020, abounding in albumen, and depositing red hæmamine on standing) were withdrawn through a fine canula. The operation was repeated in a few days, and was shortly followed by erysipelatos inflammation of the scrotum.

The volume of the tumour had now increased somewhat, and the latter was soon afterwards found resonant on percussion, there being, in addition, a good deal of serous infiltration in the cellular structure of the scrotum. Some constitutional disturbance was also present. A grooved needle introduced at the seat of the tapping gave exit to very fetid gas and a little reddish fluid. As it seemed clear that the contents of the sac had entered into putrefaction, a bistoury was passed along the groove of the needle and a free opening made, with copious escape of the gas and fluid already noted. After a little, the erysipelatos inflammation continuing to spread, the opening was further enlarged, and the interior of the sac directed to be washed out with tepid water, slightly impregnated with chlorinated lime. Next day a material, strikingly resembling faeces in colour, consistence, and odour, was observed oozing in coils from the opening.*

This material, on microscopic examination, exhibited beautiful polarizing rhomboids of cholesterine, admixed with a greasy amorphous granular matter, in which no blood cells were visible. It yielded a dirty greenish solution to caustic potass. The patient finally sank under his complicated ailments. The anterior wall of the tumour was found much thicker than could have been anticipated from its distinctly fluctuating character. About one and a half ounces of the feculent-looking matter still lay in the bottom of the sac, into which projected the slightly enlarged testicle. The structure of the latter organ was red throughout, and its natural texture apparently a good deal altered. No spermatozoa were discoverable by the microscope. The interior of the sac was nodulated, uncoated by fibrine, and partly of a dark green, elsewhere of a grey colour. Above, and quite distinct from the cavity, lay the empty hernial sac.

Whether the putrefactive changes in the sac contents (sometimes a spontaneous process) were the result of the escape of a little fresh blood into its cavity when tapped, or were due to the erysipelas which had attacked the scrotum, must remain matter of speculation. The striking, and almost startling similarity of the contents in their sensible properties to feculent matter, is an additional evidence (were such required) of the importance of the microscopic examination of such matters as an element of diagnosis.

* Doubtless altered colouring matter of the blood.

THE DODO.---At a meeting of the Zoological Society, on the 9th of January last, Professor Owen read a paper giving a full account of the discovery, and describing in detail some bones of this wonderful extinct bird, the *Didus ineptus*, which formerly belonged to the Mauritius. During the past autumn, a small morass, the "Mare aux Songes," has been drained for agricultural purposes, and during the operation these bones were discovered and collected by a gentleman residing near the spot, by whom they were sent to England for disposal. This was done by Mr. Stephens, on Tuesday last, at his auction rooms, where they were submitted in nine lots, the first of which was knocked down for £15. Mr. Flower, the conservator of the Hunterian Museum, secured the next most interesting lot for £10. The University of Oxford purchased another lot for the same amount, and a small portion went to Dublin. Altogether, the nine lots realised £83.

Foreign Medical Literature.

MEDICAL AND SURGICAL HISTORY OF THE LATE AMERICAN WAR.

THE *Philadelphia Medical and Surgical Reporter*, in its number for February 24, commences an abstract of the statistics of the military surgery of the late war, from which we select the following extracts:—

GUNSHOT INJURIES OF THE HEAD.

The number of gunshot injuries of the head so far reported is 5046. These are divided into two classes; all gunshot fractures and injuries of the cranium, and contusions of the skull resulting in lesions of the encephalon, and the simple contusions and flesh wounds of the scalp. In the first class, of 604, of which the results have been ascertained, 505 died, and 199 recovered. In 107 of these terminated cases trephining was performed, of which 60 died, and 47 recovered. In 114 cases fragments of bone or of foreign substances were removed by the elevator or forceps, without the use of the trephine, and of these 61 died, and 53 recovered. When operative procedures were instituted the recoveries were 45·3 per cent. "But," says the report, "it must be apprehended that this favourable exhibit will be materially modified when a larger number of results are ascertained, and that a great proportion of the field operations of trephining, in which the results are stated to be undetermined, were lost sight of and terminated fatally. In the 483 cases treated by expectancy, the ratio of recovery is only 20·5 per cent. But the latter group of cases includes nearly all of the penetrating and perforating fractures, and it would be unwise to base on these figures an argument in favour of operative interference."

Of 3942 gunshot wounds of the scalp, 103 terminated fatally. As far as ascertained, the fatal results have depended upon concussion or compression of the brain, or upon the formation of abscesses in the liver or lungs, in consequence of inflammation in the veins of the diploë. Compression has resulted either from extravasation of blood, inflammation of the brain, or meninges, or suppuration. The museum possesses eight examples of that rare and interesting variety of gunshot fracture of the cranium, in which the external table is unbroken, while the vitreous table is fissured and sometimes depressed. In one of these specimens, without any apparent lesion of the external table, a fragment of the vitreous plate of the frontal bone was found to be completely detached and depressed upon the dura mater. This accident is believed to result in most instances from a small projectile striking the cranium very obliquely, or from a comparatively slight blow from a body with a large plane surface.

The occurrence of hernia, or fungus cerebri, is mentioned in connexion with 18 cases of gunshot fracture of the skull, complicated by lacerations of the dura mater and brain. In four of these cases recovery took place without operative interference with the protruding fungous mass, which in these instances gradually contracted, was then covered by granulations, and finally cicatrized. In those cases in which bandaging and compression were resorted to, cerebral oppression was soon manifested, and stupor and coma eventually supervened. In those in which the tumour was sliced off, as usually recommended, at the proper level of the brain, it was commonly speedily reproduced, and death from irritation ensued.

In looking over the registers of gun-shot injuries of the head, two general facts are noticed: first, that in the after-treatment of scalp wounds a multitude of surgeons did not consider spare diet, perfect rest, and antiphlogistic measures as of essential importance; and secondly, that in the treatment of cranial fractures, the general tendency was to the practice recommended by Guthrie, in regard to operative procedures, rather than the more expectant

plan insisted upon by the majority of modern European writers on military surgery.

GUNSHOT WOUNDS OF THE FACE.

Of 4167 gunshot wounds of the face, so far transcribed, there were 1579 fractures of the facial bones, and 2588 flesh wounds. Of the former 891 recovered, 107 died, and the terminations are still to be ascertained in 581 cases.

Secondary hæmorrhage has been the principal source of fatality in these injuries. It is a frequent complication in gunshot fractures of the facial bones, and the difficulties in securing bleeding vessels in this region are very great. Recourse has often been had to ligations of the carotid, with the result of postponing for a time the fatal event. Gunshot wounds of the face, owing to the great vascularity and vitality of the tissues have commonly healed rapidly, and many plastic operations for the relief of deformities following such injuries have been accomplished. Such operations are illustrated at the Army Medical Museum by numerous casts and photographs.

GUNSHOT WOUNDS OF THE NECK, BACK, AND SPINE.

Of 1529 cases entered on the records, the ultimate results have thus far been ascertained in 546 cases, the mortality being 14 per cent.

There are eight examples of gunshot perforations of the larynx or trachea among the specimens in the Army Medical Museum. Several instances are recorded in which large grape-shot, on striking the hyoid bone, were deflected and buried themselves in the supra-spinous fossa of the scapula or among the muscles of the back. These patients died from laryngitis or œdema of the glottis, suddenly, when surgical assistance could not be immediately procured and tracheotomy performed, which might perhaps have saved them.

Of 187 recorded cases of gunshot fracture of the vertebrae all but seven proved fatal. Six of these were fractures of the transverse or spinous apophyses. The seventh case is that of a soldier wounded at Chickamauga, Sept. 20th, 1863, by a musket-ball, which fractured the spinous process of the fourth lumbar vertebra, and penetrated to the vertebral canal. The ball and fragments of bone were extracted at a Nashville hospital. The patient was transferred to Louisville, thence to Jefferson Barracks, Missouri, thence to Madison, Indiana, and finally, on July 26th, 1864, to Quincy, Illinois. The last report states that he was likely to recover.

Five thousand one hundred and ninety-five gunshot flesh wounds of the back have been recorded, of which a large proportion are injuries from shell. Troops being often ordered to lie down under a shell fire, this region becomes particularly exposed.

GUNSHOT WOUNDS OF THE CHEST.

Of 7062 gunshot wounds of the chest transcribed thus far, 2303 either penetrated the thoracic cavity or were accompanied by lesions of the thoracic viscera. The results have been ascertained in 1272 of these, and were fatal in 930, or 73 per cent. The 4759 flesh wounds presented a very small ratio of mortality, but were commonly long in healing, in consequence, no doubt, of the mobility of the thoracic parietes.

In the treatment of penetrating wounds of the chest, venesection appears to have been abandoned altogether. Hæmorrhage was treated by the application of cold, perfect rest, and opium. These measures seem to have proved adequate generally, and no instances are reported of the performance of paracentesis, or of the enlargement of wounds for the evacuation of the effused blood. Hæmorrhage from the vessels of the costal parietes or from the intercostal arteries has been exceedingly rare.

It has been the common practice to remove splintered portions of fractured ribs, and to round off sharp edges that were likely to wound the pleura or lung. After this with the exception of extracting foreign bodies whenever

practicable, and performing paracentesis when empyema was developed, it has been usual to leave these cases to the natural process of cure.

The records of the results of the so-called method of "hermetically sealing" gunshot penetrating wounds of the chest are sufficiently ample to warrant an unqualified condemnation of the practice. The histories of the cases in which this plan was adopted, have been traced, in most instances, to their rapidly fatal conclusion. Only one recorded exception can be found, in which, about a week after the receipt of the injury, much to the relief of the patient, the hermetically sealed wounds were opened, and profuse discharges of clotted blood and purulent matter escaped, after which the patient continued to improve steadily to complete recovery.

Few examples of recovery are recorded where the track of the ball passed near the root of the lung. The cases in which there was a fracture of the rib at the wound of entry, were very dangerous. The established opinion, that penetrating wounds with lodgment of the ball are more fatal than perforating wounds, was amply illustrated.

Only four cases are recorded of gunshot wounds of the heart that came under treatment. These cases are all preserved in the Army Medical Museum. The patient that lived longest after a gunshot wound of the heart, survived twelve hours, a small pistol-shot having entered the left ventricle and passed out through the right auricle.

Several most remarkable instances are quoted to illustrate recovery from wounds involving both the thoracic and abdominal cavities. We give the synopsis of one:—

Capt. Robert S., Co. A, 29th N. Y. Vols., wounded at Chancellorsville, May 2nd, 1863. A round musket-ball, fired at a distance of 150 yards, entered the eighth intercostal space of left side, nine and a half inches to the left of the extremity of ensiform cartilage, fracturing the ninth rib. Ball passed through diaphragm and entered some portion of the alimentary canal. Capt. S. walked a mile and a half to the rear, and entered a field-hospital. There the surgeons found a protrusion of the lung, of the size of a small orange, which they unavailingly attempted to reduce. The wound was enlarged, and still it was impracticable to replace the protruded lung. On May 3rd, the field-hospital lay exposed to the enemy's fire, when he walked another half a mile to the rear, was placed in an ambulance and brought to one of the base-hospitals across the Rappahannock. Here fruitless efforts were again made to reduce the hernial tumour, after which a ligature was thrown around its base and tightened. A day or two subsequently, the patient passed into the hands of Surgeon Tomaine, who removed the ligature. A small portion of gangrenous lung separated and left a clean granulating surface beneath. May 7th, the ball was voided at stool. May 8th, he was visited by Surgeon John H. Brinton, who found him walking about the ward, smoking a cigar. Entire absence of constitutional symptoms, no cough, no dyspnoea, no abdominal pain, bowels regular, appetite good. The protruding portion of the lung was carnified, and there was dulness on percussion and absence of respiratory murmur in a zone an inch and a half in width around the circumference of the base of the tumour. Hernia had been gradually diminishing in volume; it was at this time half the size of an egg, and covered with florid granulations. June 2nd, Capt. S. was transferred to Washington. There was an elastic partly reducible tumour, over which an oval granulating surface, an inch and a half by three quarters of an inch. Vesicular murmur perfect throughout the lung, except in the immediate vicinity of the tumour. Compression of the tumour was advised. After a furlough of sixty days, the wound had entirely healed; respiratory sounds were normal; there was still a slight hernia of the lung. General health of the patient excellent.

PHAROAH'S SERPENTS.—Three young workwomen entered the service of a Paris manufacturer of these toys, and, after a few days were seized with alarming illness, and removed to the Lariboisière Hospital. Their lives have been saved, but their health is for ever gone.

AN ARTIFICIAL VAGINA.

By WILLIAM H. HINGSTON, M.D., L.R.C.S.E.,

SURGEON TO ST. PATRICK'S DEPARTMENT OF THE HOTEL DIEU.

Being a Paper read before the Medico-Chirurgical Society of Montreal.

GENTLEMEN,—A recent number of the *Boston Medical Journal* furnishes details of a case of congenital absence of the vagina, in a young person of that city, which has justly been deemed of sufficient interest to obtain admission to the columns of the *Gazette Médicale*. Dr. Collins of Boston, had been consulted by a young girl, 22 years of age, who had never menstruated, and who, on examination, presented no trace of a vagina. The meatus was at the normal place, and a slight depression below it indicated the *locale* of the os externum. An examination, per rectum, established the existence of an uterus, and the report concludes thus: "The case was deemed irremediable." In reading the above report—which I have here much condensed—it is like that of a case which occurred in my own practice here, with this difference, however, the case was not deemed irremediable: and as the details may interest some of the members of the Society as they did me, I shall briefly narrate them:

In the summer of 1859, I was asked to see Miss — of this city, aged 23, who, I was informed, had never menstruated, and who suffered greatly in consequence. Miss — was a stout, red-faced girl, with bloated swollen face, and presenting an appearance of general plethora. She told me her sufferings were almost incessant, but were more severe for a few days in each month; and this condition of things had continued from the age of 11, with gradually increasing severity. Her days were passed in pain and her nights in troubled and disordered sleep, in feverish dreams, or wakefulness. Seven years before, she had, by the advice of her physician, commenced taking morphia, which she had rapidly increased in quantity, without being rendered oblivious to her sufferings; and the sleep into which she would sometimes fall, was so laboured, and her breathing so stertorous, as frequently to oblige her parents to arouse her. Several physicians had been consulted during the long course of her sufferings, and as my patient had retained a list of the medicines employed by each, it presented a most formidable array of emmenagogues, cathartics, sudorifics, and special derivatives and stimulants. As the potent armaments of the materia medica had already been pretty fairly exhausted, I proposed a tactual examination. To this, however, there were objections, until the very intelligent midwife who had been instrumental in having me consulted (and who, at my request, made an examination), had informed the patient she was unlike the rest of womankind. On inspection, the *mons veneris* was very scantily supplied with its usual covering, and the cushion of adipose tissue over the symphysis pubis was neither thick nor firm. The meatus urinarius existed at its normal site, and a little below there was a slight depression marking the place of the vagina. But there was no preputium clitoridis—no clitoris—no labiæ or nymphæ—no vestibule. An examination, per rectum, established the existence of an uterus, but, with the catheter at the same time in the ureter, no interposed vagina could be felt. I at once proposed to remedy, surgically, this anomalous state of things, hoping a division of the skin, which seemed to be thin, would lead to something like a vagina. Consent having been obtained, I made the first incision on the 23rd June, 1859, from within three lines of the meatus, to within the same distance of the rectum.

Here and there, in the line of the incision, I met with condensed areolar tissue, but no vestige of a vagina. I now made up my mind that there existed no natural passage, and that it was necessary to hew one out of the soft tissues. A day was named for the purpose, and in the meantime a large fine Turkey sponge was immersed in a thick solution of gum acacia, and submitted to enormous pressure for a few days, by which it was reduced to the thickness and hardness of sole leather.

On the 27th of June, the patient was placed under the influence of chloroform, and an incision, the length of the first, was made in the mesian line; a three-valved speculum was introduced, and through it, several narrow strips of hardened sponge. The hæmorrhage during the operation was somewhat alarming; but, after my departure, the quantity of blood lost was so great as to soak through the bed, run in a stream upon the floor, and induce frequent syncope. When hastily summoned to the bedside, I removed the thickly swollen slices of sponge by strings, which had, previous to their introduction, been attached to each piece; and employed astringent injections. The hæmorrhage gradually ceased; not, however, till I had time to reflect that Simpson's fate—under somewhat similar circumstances—was to be mine, with a *renommée*, however, less able to bear a shock which had almost unseated the advocate of hysterotomy. Two days after the removal of the sponge, I reintroduced fresh pieces through the speculum—the patient being under the influence of chloroform—and repeated this proceeding, without chloroform, every second day for a fortnight, when, by coaxing and urging, I induced the patient to submit to the knife again—assuring her friends and herself that the hæmorrhage on this occasion would be inconsiderable, as I could feel the uterus at a short distance from the wound already made. On 15th July, another and a deeper incision was directed upwards and backwards, and still in the mesian line, when the os uteri was reached—full, thick-lipped, and pouting. No discharge or secretion of any kind escaped, though an elastic bougie was made to enter the interior cavity to the usual depth. I had now a vagina formed, suited to any purpose, and the compressed sponge still increased its capacity. The sponge was removed, and fresh pieces introduced every second day for several weeks, when the speculum, covered with lint, was substituted—introduced in the ordinary way, and the handles secured together. A fortnight after the last operation a very moderate secretion took place, which increased at the succeeding menstrual periods, with complete relief to all those distressing symptoms for the relief of which she had consulted me. The morphia was laid aside, and sleep, without it, was sound and refreshing; and the patient, from a bloated, swollen, and apoplectic-looking object, became as slender and as genteel as she could have desired. The dilating process was continued several months. Some time ago, I was asked my opinion concerning her marriage (then on the *tapis*), and, after an examination, unhesitatingly counselled it. (The smooth walls of the artificial vagina were now lubricated with a secretion, and the organ was of the ordinary capacity.) The marriage took place, and now I have to mention what to me appears the most remarkable circumstance in the case. Previous to the operation there was no sexual desire, but when menstruation had been fairly established there was a difference in that respect. The patient has not become pregnant. These are briefly a few of the more salient points of a case which had much interested me. I have consulted every work within my reach for details of a similar one, but could find none, till the report of that of Dr. Collins, above-mentioned, attracted my notice.—*Canada Medical Journal*.

PLACENTA PREVIA.

The Transactions of the New York State Medical Society for 1865 contain an elaborate paper "On the Anatomy, Physiology, Pathology, and Treatment of Placenta Previa," by Prof. Isaac E. Taylor of Bellevue Hospital, illustrated by diagrams and drawings. He concludes with the following propositions:—

1. The perfect integrity of the cervix uteri during utero-gestation in its whole length, without developing from above downward, or from below upward, but modified by physiological softening to prepare it for the office of expansion at the time of labour, and not before, for the exit of the child.

2. That the placenta previa centralis is over the so

uteri internum, and not in the cervix uteri at all, before labour commences, as is believed or demonstrated.

3. That the limit of spontaneous detachment of the lower polar circle, the boundary line of Dr. Barnes, is not the zone of safe attachment after separation of the placenta.

4. The cause of arrest of the flooding in general is the limit of expansion of the os uteri internum to the extent of twelve or fourteen inches in circumference, and three and a half to four in diameter, and three inches long.

5. That the boundary line thus reached by nature is only safe so far as separation occurs by the contractions of the uterus.

6. That the hæmorrhage comes from the uterus as seen and not from the placenta.

7. That the flooding is diastolic, not systolic.

8. That the method of separation of the placenta by the uterine contractions is from the centre and not from the margin.

9. That the method of Dr. Simpson is preferable in cases of extreme exhaustion to version, until nature can be restored in some degree to perform it.

10. That external version should be adopted first in transverse presentations of the shoulder, neck, or face, before rupturing the membranes; if not successful, then internal and external version together, then true version, but not rapidly, if the other methods fail.

11. That the former and usual methods are confirmed by these investigations in their value, such as tamponing and rupturing the membranes, and giving ergot.

STATISTICS OF THE CONFEDERATE STATES ARMY, ON AMPUTATION, DISARTICULATION, AND RESECTION.

AMPUTATIONS of the thigh, whole number, 507; primary, 345; recovered, 213; died, 132; 38 per cent.; secondary, 162; recovered, 43; died, 119; 73 per cent.

Amputations of the leg, whole number, 464; primary, 314; recovered, 219; died, 95; 30 per cent.; secondary, 150; recovered, 76; died, 74; 49 per cent.

Amputations of the arm, whole number, 434; primary, 294; recovered, 252; died, 42; 14 per cent.; secondary, 140; recovered, 87; died, 53; 37 per cent.

Amputations of the fore-arm, whole number, 114; primary, 69; recovered, 61; died, 8; 12 per cent.; secondary, 45; recovered, 35; died, 10; 22 per cent.

Disarticulations, whole number, 135; primary, shoulder-joint, 79; recovered, 54; died, 25; 31 per cent.; primary, elbow-joint, 4; recovered, 3; died, 1; primary, wrist-joint, 7; recovered, 5; died, 2; primary, hip-joint, 3; recovered, 1; died, 2; primary, knee-joint, 5; recovered, 2; died, 3; secondary, shoulder-joint, 28; recovered, 8; died, 20; 71 per cent.; secondary, elbow-joint, 3; recovered, 2; died, 1; secondary, knee-joint, 6; died, 6.

Resections, whole number, 130; primary, shoulder-joint, 41; recovered, 28; died, 13; 27 per cent.; primary, elbow-joint, 25; recovered, 22; died, 3; primary, wrist-joint, 2; recovered, 2; primary, knee-joint, 2; died, 2; secondary, shoulder-joint, 26; recovered, 19; died, 7; 21 per cent.; secondary, elbow-joint, 29; recovered, 23; died, 6; secondary, wrist-joint, 1; recovered, 1; secondary, hip-joint, 2; recovered, 1; died, 1.

Amputations of the foot: primary—Chopart's, 16; recovered, 13; died, 3; Symes's, 2; recovered, 2; Pirogoff's, 4; recovered, 2; died, 2; secondary—Chopart's, 8; recovered, 7; died, 1; Symes's, 4; recovered, 4 (1 unsuccessful, requiring subsequent amputation above the ankle-joint).

A vast number of additional operations are received, but without positive results, and therefore they have not been included in the above list.

We may well be satisfied with the results of these statistics, which, carefully excluding all doubtful cases, are compiled from those operations only that have reached a positive conclusion. A general summary of the above table shows that the mortality after 1814 operations, in-

cluding amputations, resections, and disarticulations, amounted to 632, giving a death ratio of 34 per cent.

The only statistics on this subject from the Federal army we find in the "United States Army and Navy Journal," for November, 1863, which gives the amputation statistics for September, October, November, and December of 1862, as follows:—Whole number, 1342; deducting 516 under treatment January 1, 1863, 826. Of this number 336 died; a mortality of 40 per cent.

The journal to which we owe the above observation gives the following table: Whole number, 1342; returned to duty, 100; furloughed, 25; deserted, 11; discharged, 350; died, 336; secondary operation, 34; under treatment Jan. 1, 1863, 516.—*Confederate States Medical Jour.*

THE ICE-BAG TREATMENT OF CHOLERA.

DR. MACLEAN, in a lecture at Netley, thus speaks of the ice treatment of cholera:—

"I had the pleasure of meeting Dr. Chapman in Southampton when he came down to put his ice treatment to the test of experience, and I had the advantage of hearing him expound his views at a meeting of one of the Southampton Medical Societies. I took the liberty on that occasion to say that, although I differed materially from Dr. Chapman as to the mode in which the disease is propagated, I would gladly give his method a fair trial; and had the disease appeared in the Royal Victoria Hospital, I was prepared to do so. I do not think that the result of the trials of this method at Southampton were sufficiently extensive to warrant any confident opinion one way or the other. I have had too much to do with cholera to rush into large conclusions as to the effects of remedies in ten or a dozen cases. Every person smitten with cholera does not, as a matter of course, die; but judging from recent cholera literature, in every case where death does not occur, the fortunate issue is, without hesitation, put down to the remedies used; and if we have regard to the variety and number of these remedies, to say nothing of their opposite qualities, the result is very puzzling to those who do not reflect on the fact, that a certain number of people recover under every variety of treatment not positively hurtful, and, I may add, quite as many where no 'treatment' in the shape of drugs has been used at all. Dr. Chapman has since, I understand, had an opportunity of trying his method on a larger scale in Paris. I am quite prepared to hear that this more full experience has tended to lessen the confidence with which Dr. Chapman was inspired when I had the pleasure of meeting him here. The powerful action of ice to the spine on the uterus has been pointed out by Dr. Chapman. It was well illustrated in one of the cases of cholera at Southampton. The application of ice to the spine of a woman profoundly collapsed brought on the menstrual discharge, which had ceased for ten or twelve days. This, as Dr. Chapman has himself shown, should be kept in mind, as otherwise in pregnant women unpleasant consequences might result from the application of the ice-bag low down on the spine."—*Brit. Med. Jour.*

AUTOMATIC REGISTERING AND PRINTING BAROMETER.—The *Philadelphia Medical Reporter* says:—"We have received an account of this remarkable invention by Prof. G. W. Hough, Director of the Dudley Observatory, Albany, N. Y. We have not space to give a description of the machine. Suffice to say, that it is operated by means of electro-magnetism, and makes a continuous and permanent record of the fluctuations of the barometer or thermometer. We have such a record before us, showing the fluctuations of both instruments during the cold term, Jan. 7th and 8th, 1866, when the thermometer fell to 18° below zero, and the barometer reached the extraordinary height of 31.10. It is a noticeable fact that the fluctuations of the two instruments are in opposite directions—for every elevation of the barometer there is a corresponding depression of the thermometer, and vice versa. Thus, when the barometer stood at 31.10 as above, the thermometer was at—18°.

COLOTOMY (AMUSSAT'S OPERATION)

FOR THE RELIEF OF
CANCER OF THE RECTUM.

PROF. G. C. BLACKMAN, in the *Cincinnati Journal of Medicine*, relates a case of cancer of the rectum, in which Amussat's operation for Colotomy was performed by him with success. Dr. B. strongly argues in favor of the operation, spite the objections raised by many eminent surgeons.

The patient was a coloured man, 35 years of age, patient of St. John's Hospital, Cincinnati, whose rectum up as far as the finger could reach (some three or four inches), was filled with a fungous mass, bleeding freely from the slightest touch, and giving rise to a sanious discharge, with the characteristic odor of malignant disease. Some time before the operation, his bowels had been extremely costive, and unable or unwilling to take solid food, he had rapidly emaciated.

October 15th, 1866, he was operated on; the left descending colon being exposed in the lumbar region, and secured by means of a ligature, an incision was made into the bowel of about one and a half inches. The intestine was then fastened to the lips of the wound by several interrupted sutures. On incising the colon, neither feces nor flatus escaped, but with the finger the solid contents of the bowel could easily be reached. The stitches were not removed until the ninth or tenth day, when a dose of castor oil was administered, and fecal matter passed freely, both by the artificial anus and the rectum. From that time until the date of reporting (Dec. 26th) the fecal matter has passed altogether through the artificial opening. The patient has used freely of solid food, and gained rapidly in flesh and strength. Has had two attacks of hæmorrhage from the fungous mass within the rectum, one of which requiring persulphate of iron to arrest it; otherwise his improvement has been gratifying. Since the operation he has occasionally, from imprudence in eating, been troubled for a day or two with diarrhoea and incontinence, but as a general rule, the artificial anus gives him no trouble. He suffers no more from the excruciating tortures which rendered him, before the operation, so miserable, and threatened to terminate his existence; and he declares that, even if his life should not be prolonged another day, he has been amply repaid for submitting to the operation.

FISTULA IN ANO: OPERATION BY LIGATURE MODIFIED.

DR. A. W. THOMPSON of Northampton, Massachusetts, communicates, in a recent number of the *Boston Medical Journal*, a modified mode of operating for fistula in ano by ligature, which he has successfully used in cases where, by complicating circumstances, the ligature promises better results than the knife. It is described as follows:—

"A ligature of four lengths of saddler's silk having been introduced and left as tight as could be borne, on the first evidence of its advance toward the surface—slackness in the portion outside—a C-spring of thin rubber, notched at its extremities that it might be held in place, was inserted under the loop of the cord, its convexity directed toward the skin, and its notched ends receiving the cord, strained into them by the action of the spring. As much strain was thus applied as the patient could endure. From day to day new springs were added, or longer ones substituted, as more and more of the ligature appeared outside, until in a few hours short of eleven days it dropped away and the cure was complete." The spring is easily cleaned, absorbing no fluid, and admits of the application of poultices which may be required.

FATAL ACCIDENT TO A PHYSICIAN.—On the 16th ultimo, Dr. Mount of Cincinnati was struck behind the ear by the pole of a carriage driven at an illegal rate of speed along the street, and died the next day.

RETROSPECT OF MEDICAL JOURNALS.

THE *Lancet*, in very flattering terms, draws attention to the condition of the Jewish poor in London, regulated as they are by a Board of Guardians of their own, and depending on their own race for charity. It is very creditable to find this race, in the midst of aliens, in every country preserving their ancient customs so distinct that they would rather not eat food with their neighbours, and yet living peaceably among them—a pleasing contrast with other countries, where, from the evils of mixed resident races, the most disastrous consequences have ensued, as evidenced by the late outbreaks in India and Jamaica.

A good deal of notice is now being taken of the smoke nuisance, which in a great measure could be obviated by the adoption of smoke sewers; even in an economic point of view it is to be warded against, as it has been computed that over one-fourth of the fuel is wasted by the unconsumed carbon passing into the general atmosphere, there to form a nuisance.

Dr. B. Jones' lectures on Diseases resulting from Peroxidation, are continued. On the subject of lemon juice he has the following:—"Of all the acids lemon juice is perhaps the best which can be used. Many years since Mr. Witt made the following analyses of lemon juice for me (see *Quarterly Journal of Chemical Society*, vol. vii., p. 44):—One ounce (480 grs.) of lemon juice contains only 1.728 grs. of inorganic constituents; of which potash, sulphuric and carbonic acids constitute three-fourths; phosphoric acid, soda, and lime, with traces of silica, and iron and magnesia, constitute the other fourth. Hence water and citric acid constitute by far the largest part of the lemon juice, the citric acid being, on an average, about 40 grs. to the ounce of juice. It is highly probable that citric acid and other vegetable acids have an anti-inflammatory action (lessening the oxidation that is going on) wherever they are carried, and they not only pass to the kidneys, but probably diffuse into every part of the mucous membrane of the bladder; to a small degree lessening the alkaliescence of the textures in which the peroxidation is going on." This he uses in cases of ammoniacal urine, drawing off the urine several times daily by a catheter.

Dr. Tilbury Fox mentions a preparation, termed the wheat phosphates, as very useful in many diseases the result of mal-assimilation. It is obtained from the husk or bran, and contains phosphates and other important matters which are deliberately rejected in the best flour. He has tried it in rickets marasmus, chronic diarrhoea, eruptive diseases of the scalp.

Dr. Morrel Mackenzie's paper on Dysphagia is an excellent practical dissertation on a subject but little treated of in text books; we would recommend its perusal to every medical man. The symptom he treats of is one met with in many diseases; and, as the part engaged is within view, or at any rate can be got at by the surgeon, it is comparatively more manageable than Dyspnoea.

The "Entozoa" have been rearranged in the Hunterian Museum, under the superintendence of Dr. Cobbold, whose labours in this field have gained for him a world-wide reputation.

It turns out that the statement as to the bleeding of Mr. Gibson the sculptor, at Rome, is incorrect.

Dr. Herapath, at the Mountain Ash murder trial, was able to aver that certain stains on a hatchet were blood stains. He used the microspectroscope in the investigation.

The University of London has held a convocation, at which a resolution was come to that Parliament should be petitioned for the privilege of sending two representatives on behalf of the University to the House of Commons. The constituency is about 1800.

A correspondent draws attention to the many instances of fraud practised on young men purchasing practices.

In the *Medical Times and Gazette* Mr. Hutchinson's admirable lectures on Fractures and Dislocations are continued. The method he adopts, in effecting reduction of

a dislocation into the axilla, is that of drawing the arm straight away from the side, and then suddenly bringing it towards the body, across the surgeon's knee, in the axilla. He also gives the particulars of a case in which suppuration of the shoulder and death followed his attempts to reduce an old dislocation.

Mr. Rundle describes a very interesting case of gunshot wound, in which a bullet was lodged in the abdomen for seven years and a half. It subsequently made its way into the alimentary canal and caused strangulation of the intestine.

Mr. S. Wells has had a case in which he performed ovariectomy. After the operation it was ascertained that the tumour and peritoneum were a mass of cancer.

Mr. Lane was obliged to apply a ligature to the femoral artery, having previously failed to cure the aneurism by compression and forced flexion. The ligature came away on the 20th day.

The *British Medical Journal* very justly remarks on the discontent of the army and navy medical officers. It fears that their openly-avowed opposition will in a great measure prejudice their cause:—"From a full knowledge of the history of army and navy medical grievances, we have no hesitation in saying that, if the recommendations alluded to fail to give contentment, there is little hope that anything which can be done by the authorities will ever satisfy the discontented. We believe that the complaints in question are the complaints only of the few. We should, indeed, be paying a very bad compliment to our army and navy medical brethren, as a body, if we supposed them capable of making such unreasonable objections. What must and will authorities naturally say, when they find that recommendations of the removal of every grievance heretofore complained of by army and navy medical officers, and, in addition, of a very considerable increase to their pay, are received with marked signs of discontent? We believe these expressions of the

operate very seriously to the injury of both services. We candidly confess that, if the very best intentions and very liberal efforts of the authorities are received in this wise, no one can blame them if, in settling the recommendations made in the reports, they take these expressions of discontent as a sign that it is useless for them to attempt to satisfy the demands of the army and navy medical services. It must be remembered, that the Reports have not yet been discussed and settled by the authorities; and we leave every man of common sense to reflect upon the feelings of those authorities, who sit down to discuss the reports with a foreknowledge that the very liberal terms contained in them are already stigmatised as unsatisfactory. Most assuredly, the profession at large can have no possible sympathy with such unreasonable and most unseasonable expressions of discontent. Comments on the reports such as are contained in a pamphlet just issued by Dr. Brown will, we fear, prejudice the minds of the Admiralty Lords when they come to consider the Committee's most liberal recommendations. The Lords may say: It is evident that no efforts of ours will satisfy these gentlemen."

Dr. A. Smith has analyzed some air collected from the Court of Queen's Bench during a sitting. He has found that it is far inferior to any collected during the same day in any inhabited place above ground, and that it closely resembles the atmosphere of metalliferous mines.

Reminiscences of a Four Months' Stay with Prof. Von Græfe at Berlin, is a very interesting paper by Dr. Samuelson. Communications like it are instructive, and relieve the monotony of a scientific journal.

Meetings of Scientific Societies.

ENTOMOLOGICAL.—Feb. 5.—Sir J. Lubbock, Bart., President, in the chair.—The prize awarded by the Council for an essay, "On Ailanthiculture," was presented to the author, Dr. A. Wallace.—Prof. Westwood exhibited a pair of the dog-tick, *Ixodes plumbeus*, which he had kept without food in a glass tube for twelve months, having taken them

away with him from the meeting of this Society held in February, 1865, when they were produced by Major Cox; shortly afterwards a number of young ones were observed in the tube, which, however, soon died; but the tube was now again thronged with young in the hexapod state; the female parent was no longer living. Prof. Westwood also exhibited a larva with long filaments at the sides of the body, which he at first thought to be Neuropterous (*Sialis*) and afterwards Lepidopterous (*Hydrocampa*); but which, from an examination of De Geer's figures, he believed to be in truth Dipterous, and to be the larva of *Tipula replicata*; it was found in damp moss, in Derbyshire, and there could be no doubt that the filaments were branchial respiratory organs.—The President exhibited magnified coloured drawings of two larvæ, one Lepidopterous, the other probably Coleopterous.—Mr. F. Smith said that the doubt he had expressed at a former meeting as to the tapping noise alleged to be made by the "death-watch," *Anobium*, had induced Mr. Doubleday to write him a letter, which showed that his doubt was unfounded. Mr. Doubleday stated that the beetle produces the sound by raising itself up on its legs as high as it can, and then striking the head and under part of the thorax against the substance on which it is standing; the noise was evidently a call-note from one individual to another, and he had rarely heard its without its being immediately answered. He had repeatedly kept an *Anobium* in a card pill-box, and if the sound was imitated by tapping any hard material with a pointed pencil, the prisoner would instantly reply.—Mr. Wallace mentioned, that on recently repairing the oak roof of an old church at Colchester, which had been attacked by *Anobium*, it was found that the damage was chiefly confined to the south side, the other side being but slightly affected.

THE Entomological Society of Philadelphia have set themselves to propagate information on practical entomology, with a view to induce agriculturists to study the insects in their several neighbourhoods, and thereby discover a way to prevent or mitigate the mischief occasioned by what is generally described as "blight," or "the fly." "It is a singular fact," remark the Society in their preliminary circular, "that some of our commonest and most injurious insects are least known. Our cotton, hop, and various other crops suffer at times immensely from insects whose habits we little understand." And they seek to bring out the true history of each and all of the noxious insects of the States, believing that when this is accomplished, simple remedies will suggest themselves, which in certain cases may prove to be burning the stubble, and ploughing vigorously in the fall (autumn). Perhaps there is something in this from which British entomologists may take a hint.

RINDERPEST IN SHEEP.—The murrain caused in Scotland by the alleged outbreak of rinderpest in sheep has been to some extent mitigated by the investigations into the circumstances of the cases. In the Fifeshire cases undoubtedly the testimony of the professional inspectors as to the disease being rinderpest is distinct and decided, but great reluctance is shown on the part of practical men to accept their opinion without further inquiry. Into the Forfarshire cases a very careful investigation is being made by the Chamber of Agriculture, and an interim report has been issued stating the symptoms and circumstances. In these cases the local inspector was unable to pronounce that the disease was rinderpest, and, on being questioned by the committee of the Chamber, he acknowledged that he had seen similar symptoms in other diseases. Professor Strangeway, of Edinburgh, has been appointed meantime to go and examine the flock said to be affected, while the head and intestines of a sickly sheep, slaughtered for the purpose of the inquiry, have been already examined by him, and said by him to show much less distinct appearances of rinderpest than the Fifeshire cases, although the symptoms were such as might indicate an early stage of that disease. Meantime, the Chamber suspend the expression of their own opinion; but, looking to the mortality usual at the lambing season the severe snowstorms prevailing in Scotland for the last fortnight, the mildew in the turnips, and the change in the diet of the affected flock lately brought from Berwickshire, it seems to be the opinion of those who have examined the circumstances that the disease in the flock may be otherwise accounted for than by ascribing it to rinderpest.

Reviews.

HANDBOOK FOR YELLOW FEVER AND PESTILENTIAL CHOLERA, AND A METHOD OF CURE. By Dr. THOMAS ANDERSON. 1866.

THE author of this little book does not expect much commendation from the profession, appealing rather to the community at large in its favour. We leave it to his own reflection, is not this rather an unusual course, and one not likely to enlist professional men in his behalf. We are disposed to agree to his claim for it of originality, as certainly in some respects it is so. However, we think we will be able to give it a degree of commendation, notwithstanding the Doctor's slight estimate of his own profession, which we to some extent attribute to his 50 years' West India life.

Dr. Anderson must excuse our passing over information as to his studentship and as to his testimonials.

Yellow fever, Dr. Anderson thinks, may originate in the first instance from atmospherical causes, fostered in instances by local impurities, and in concentration emitting mephitised effluvia, which, once engendered, may and do acquire an infectious property. The persons principally subjected to attack are those of rigid fibre, recently arrived in the tropics, such as unacclimated soldiers and sailors, "abounding in rich glutinous blood," &c. He regards yellow fever as, under certain circumstances, taking on an infectious property.

Bleeding may, as a general rule, be dispensed with. However, "there are cases," says the Doctor, "where it may be resorted to in moderation—in the early onset, that is to say, where there is much plethora, or an inflammatory or rheumatic tendency, but not so as to weaken the circulation, but only to ease it; not to impair the reactive powers of the septum, always the result of inordinate detraction of the vital fluid."

Calomel^o and quinine, not used heroically but in moderation, constitute a rational mode of treatment. Instances of fatal results, apparently from enormous doses of each, are given. The evil of large doses of calomel, especially when combined with the use of acids, is forcibly shown by what occurred in the Doctor's experience.

Castor oil has been found by our author as a severe irritant, and he now only uses it as an enema, and then with caution, suspended in mucilage or albumen. We find, however, that in the treatment followed by Dr. Anderson and Dr. Littlepage, in cases of yellow fever on board H.M.S. *Hightyer*, in 1852, calomel in a ten-grain dose and castor oil constituted part of the treatment which was considered as very successful. This does not altogether agree with what we have already quoted. In no case of the epidemic of 1852 was bleeding employed; in some cases no calomel was taken, and wine and porter were given with due caution from first to last. "No prescribed line of practice can be applicable to all cases," &c.

In the early stage of cholera cases—those that did not prove rapidly fatal without premonitory symptoms—where cramps and vomiting existed, Dr. Anderson found a mustard emetic acted well, and he followed it up by a drachm dose properly diluted, of ammoniated tincture of opium; if rice-water stools begin, he abandoned all forms of opium and trusted to ammonia: a fluid drachm of aromatic spirit of ammonia—or some carbonate of ammonia—with a glassful of Seltzer water, given at once and repeated hourly in half the quantity till the frequency of the discharges is checked. This commonly takes place in a few hours, if given early; but if cholera stools should have been some time present, he gives the remedy every half hour. If rejected by vomiting, he perseveres, nevertheless, when the stomach generally gets settled. Thus treated, I have seen (says Dr. Anderson)

numerous cases rally even from collapse and permanently recover.

We have thus briefly reviewed Dr. Anderson's little work, which bears the impress of a man of straightforward purposes; and when we consider his large experience after half a century in the West Indies, we have no hesitation in recommending it to those of our readers who are likely to encounter climates resembling that of Trinidad. We do not, however, agree with the Doctor in his statement that he had discovered a certain and effectual remedy (in ammonia) for cholera, early in the disease and often successful even in its advanced stages.

TRANSACTIONS OF THE OBSTETRICAL SOCIETY OF LONDON. Vol. VII. for the year 1865. Pp. 335. London: Longmans. 1866.

THE Reports given from time to time of the proceedings of the Obstetrical Society in the Medical Journals have kept the profession acquainted with the general features of the subjects discussed at the periodical meetings; but the publication of the Transactions in a separate volume is of enduring value, by presenting at one glance the whole of the topics introduced during a given year, and so copiously illustrated with plates that any deficiency in the descriptions is amply supplied by the visible representation of the parts or objects described. The volume now before us contains, as usual, a faithful record of patient work performed by the members of the Society during the year 1865, and is quite equal to its predecessors, which is no small praise when we recollect the former excellent year-books produced by the Society. We are happy to find that the finances of the Society are in a very flourishing condition; that a profit is obtained from the sale of the "Transactions," over and above their distribution to the members; that a library has been established at Mr. Hardwicke's, in Piccadilly, where books may be taken out for perusal under certain regulations; and that the present number of fellows amounts to no less than 512, some of whom are dwelling so far away as Australia, New Zealand, and Madras.

SOME EFFECTS OF THE CLIMATE OF ITALY. By THOMAS KING CHAMBERS, M.D., Consulting Physician and Lecturer on the Practice of Medicine at St. Mary's Hospital. Pp. 95. London: Churchill and Sons. 1865.

DR. CHAMBERS having been compelled, in consequence of a very serious illness, to relinquish his practice for a considerable period, he repaired to Italy for the purpose of renovating his health, and the small volume with the above title contains the substance of a short course of lectures delivered at St. Mary's Hospital, and lately published in the pages of a contemporary journal. The first part contains some interesting but painful particulars of Dr. Chambers's own illness—which, however, we are glad to find that his sojourn in Italy has dissipated,—and a few general remarks on degenerative disease, and the best methods of treating this condition. The second part contains a collection of statistical facts relating to the proportionate prevalence and to the greater or less gravity of chronic diseases in Italy as compared with England, and to other similar questions; the results being that chronic diseases are more fatal and probably more prevalent in London than in an Italian town similarly circumstanced to our own metropolis. The third part explains the powers of the Italian air over the human constitution; and the fourth part is devoted to the practical application of the principles laid down in the preceding chapters. Thus the most eligible spots are pointed out for the visits of the invalid, and the time of the year when the visits should be made; and due precautions are laid down for his special guidance under the various conditions of his disease. Altogether, this little book is a very readable one

for all classes, and will doubtless be found particularly useful for those who are induced to repair to Italy for the restoration of their health.

A MANUAL OF MINOR SURGERY AND BANDAGING, FOR THE USE OF HOUSE-SURGEONS, DRESSERS, AND JUNIOR PRACTITIONERS. By C. HEATH, F.R.C.S., Assistant-Surgeon to and Lecturer on Anatomy at the Westminster Hospital. Third Edition. Pp. 249. London: Churchill and Sons. 1866.

THE fact that this manual has reached a third edition sufficiently testifies the estimation in which it is held by those for whose instruction it was written. It is in fact a very useful little book, and contains a great amount of information not generally to be found in large treatises on surgery; and not only will its precepts be found available for the subordinate members of the surgical staff at the hospitals and for junior practitioners, but many a surgeon engaged in the full performance of the duties of his profession will find a great number of valuable hints, which he may turn to advantage in his daily avocations.

AN INTRODUCTION TO PRACTICAL CHEMISTRY, INCLUDING ANALYSIS. By J. E. BOWMAN, F.C.S., late Professor of Practical Chemistry in King's College, London. Edited by CHARLES L. BLOXAM, F.C.S., Prof. of Practical Chemistry in King's College, London. Fifth Edition. Pp. 316. London: Churchill and Sons. 1866.

THIS excellent little work having rapidly run through four editions, a fifth is now presented with such alterations and additions as the advance of the science renders expedient. But in the preface Mr. Bloxam, after adverting to the recent changes which have been adopted by many teachers in the formulæ of chemistry, states that he does not introduce them into his present edition, in order to avoid theoretical explanations in what ought to be a purely practical work. He has therefore omitted these and other symbols and equations, leaving the student to refer to them in systematic treatises embracing the whole science of chemistry.

ON HIP-JOINT DISEASE, with reference especially to Treatment, by Mechanical Means, for the Relief of Contracture and Deformity of the Affected Limb. By Wm. CURTIS HUGMAN, F.R.C.S. Second Edition. Pp. 95. London: Churchill and Sons. 1866.

ALTHOUGH this work gives a general account of the nature, pathology, and treatment of hip-joint disease, its chief object, as expressed in the title-page, is to recommend a particular mode of mechanical treatment, with the object of preventing the lameness and distortion which often follow the primary affection. The plan consists principally in placing the patient upon a prone couch having a horizontal plate for the support of the head and chest, and an inclined plane for the lower extremities, so divided as to be capable of extension on the affected side; and then, by attaching weights to the frame of the sliding mattress, causing traction to be made on the contracted limb in such a manner as to cause its elongation. Mr. Hugman records several cases in which this plan has been successfully pursued, and he illustrates the treatment and its results by means of several plates.

RICHMOND MEDICAL JOURNAL. No. 1. January, 1866.

NEW YORK MEDICAL RECORD. No. 1. March, 1866. New York: Messrs. Wood & Co.

THE issue of these journals, one from the Federal chief-town and the other from the Confederate head-quarters, are a practical evidence of the recovery of our transatlantic friends from the war paralysis which had so injuriously affected medical journalism, in common with all other business excepting war contractors and ministerial jobbers.

Hardly a single medical journal lived out the struggle, and there is therefore a wide field for the new competitors. The *Richmond Journal* is a monthly of 80 pages, and opens its issue with a very fair programme. Amongst the original matter is an interesting paper on the "Relation of the Periosteum to Osteo-genesis," by Dr. Gaillard. No. 1, however, depends a good deal on its Retrospect and Eclectic Department, and future issues may be reasonably expected to show an improvement in the original division.

The *New York Medical Record* is bi-monthly, and more like our weeklies. Its matter is extremely good on the whole, with a slight dilution of what printers call "filling-up stuff." Here is its programme of original matter:—

"On Centric Hypertrophy of the Prostate. By W. H. Van Buren, M.D., Professor of Anatomy in the University of New York. A Case of Complicated Double Hare-Lip and Cleft Palate. By Gurdon Buck, M.D., Surgeon to the New York Hospital, &c. &c. Cases of Aphasia with Hemiplegia. By Austin Flint, M.D. The Gutta-Percha Shoe in the Treatment of Talipes. By Alfred C. Post, M.D. Blepharitis Ciliaris and Phlyctenular Conjunctivitis. By E. Williams, M.D. A Lecture on Accidental Puerperal Hæmorrhage. By T. Gaillard Thomas, M.D."

It has also a good series of Hospital Reports. On the whole, the journal bids fair to be a reliable representative of American Surgery, and as such it has its place.

THE ANATOMICAL REMEMBRANCE, or Complete Pocket Anatomist, containing a concise Description of the Bones, Ligaments, Muscles, &c. &c. Sixth Edition. London: J. Churchill and Sons, New Burlington-street. 1866.

IN recommending the sixth edition of this admirable little work to the notice of the Profession, we would warn our readers against trusting to it alone; it is only intended as an epitome, and a very short one too, of a subject requiring long and patient labour. To make use of it, it should be learned off by heart. It is useless in the dissecting-room or the study, but is a most invaluable pocket companion in a railway carriage, or while waiting for lecture. The descriptions are so short that it puts us in mind of a dictionary. Its successful career through five editions already is an evidence of its reputation.

TUMOUR OF THE BRAIN: INTERMITTENT EMPROSTHOTOSIS.—Dr. Gemma relates the case of B. C., aged 5, the offspring of parents affected with pellagra. She had always enjoyed good health, when her catamenia were arrested without apparent cause. One day she was suddenly seized with violent pain in the forehead, and uttered a cry; her jaws then became closed, and her head bent forward. She indicated by gestures that she understood all that was said, but could not open her mouth. The attack lasted about three hours, at the end of which time the symptoms ceased, leaving only slight confusion of intellect, which disappeared the next day. These attacks recurred every fifth or sixth day; her health in the interval being apparently perfect. Four months passed in this way without any change, during which time she was bled, and took purgatives and iodide of potassium. At last an attack took place which was attended with loss of intelligence, sensation remaining. The pulse was hard and slow. At the end of an hour, the patient made some movements with her arm; then sank and died. At the post-mortem examination, the arachnoid was found to be much congested. The left cerebral hemisphere was very soft; and there was a similar lesion, but less marked, in the corresponding hemisphere of the cerebellum. In the middle of the left hemisphere was found a tumour of the size of a hen's egg, formed of a gelatinous matter with a nucleus as hard as fibro cartilage in its centre. The right hemispheres of the cerebrum and cerebellum, the corpus callosum, and the medulla oblongata, presented no change. The intestines were slightly injected; the other viscera presented no signs worthy of note.—*Gaz. Med. Ital. Prov. Vnet.*

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 28, 1866.

THE CATTLE PLAGUE AND ITS LESSONS.

It is an old saying that we ought not to exult till we are out of the wood, and in the present rather uncertain position of the returns relating to the cattle-plague it would be perhaps premature in us to declare that we have seen the worst of the recent epizootic pestilence; but still we have reason to rejoice that, whether from the actual decline of the disease or from the abundant contributions we are obtaining from foreign sources, the supplies of meat to the community are sufficient for its wants, and the price of the article is not materially affected. Indeed, if we are to believe the reports we receive, the wholesale price of meat has diminished in the chief metropolitan market, although the traffic in live beasts is entirely or almost entirely suspended, and the supply is derived mainly from the carcases of the animals brought by the steamers or the railways. The principles of free trade and their practical application have therefore succeeded in averting from our homes a calamity only inferior to a dearth of corn, and in attracting from distant regions of our own empire and from foreign countries a supply of food-material, in which, for the time, the soil of England is unfortunately somewhat deficient. We qualify the word "deficient," because we think that the deficiency has been relative rather than absolute throughout the whole country; and although some of the English and Scotch counties have suffered very severely, others have been very lightly visited or not at all, as in the case of the metropolis itself, in which the disease has made but very little progress.

It would appear that, as regards the operation of the Cattle Diseases Act, very few people have any valid cause of complaint, and many, perhaps, may find in it subjects of congratulation. The wonderful alacrity with which the Bill was passed, almost without opposition, in both Houses of Parliament, was obviously due to the personal property of the landowning and farming interests being compromised by the ravages of the plague, while any contingent animosity to the measure would be more than conciliated by the clauses ordering compensation for the cattle destroyed. In fact, it seems at present that the farmers and others are showing an almost unnecessary zeal in promoting the slaughter of their cattle for the sake of the rewards to which they are thereby entitled, while some of those who are obliged to contribute to the payment of the compensations are beginning to grumble at what appears to be a superfluous waste of bovine life. The butchers, again, have no cause to complain, but probably the reverse, for they raised the price of meat on the first

threatening of the pestilence; they maintained the prices on the ground that an actual scarcity would soon arrive, and now they delay the reduction in the rates, although the wholesale price of meat has been diminished.

We have already stated that the cattle plague has its lessons; and one which it has taught to all practical men is, that the members of the British Legislature are quite alive to their own interests. If the question had been, whether some fifty thousand paupers were sickening, and many of them dying from typhus fever, it is very likely that the Lords and Commons would have thought the matter beneath their notice, and would have left it to the tender mercies of the local guardians, and other such authorities. We know that the small-pox is allowed to perpetuate its ravages on the human race in our islands, because, forsooth, it is alleged that a compulsory system of vaccination would interfere with the liberty of the subject, and would tend to encourage centralisation. But because the pockets of many of the Lords and Commons are affected by a sporadic murrain among the horned cattle, stringent measures are at once taken to stop the transit of the beasts, to override the authority of local boards, to slaughter animals either actually diseased or supposed to be so, and to compensate the owners for the losses thus occasioned. The bugbear of centralisation becomes at once an antiquated and obsolete myth, and the community are compelled, under the most severe penalties, to comply with the Act of Parliament, however onerous its provisions may be to individuals or to local governments. Why, if one half, or one-tenth, of the energy and decision shown in this matter, had been exhibited in promoting the efficient performance of vaccination, small-pox might have been exterminated from the British soil, as it has been from some other countries, where local government is not so excessively worshipped as it is in our favoured country. So too if the principles of salutary centralisation had been brought to bear upon the suppression of typhus fever, or the improvement of the condition of the sick poor in the workhouses, an immense amount of human suffering would have been spared; thousands of valuable lives might have been saved; and even taking a low pecuniary estimate as the basis of calculation, a large sum of money in the shape of allowances to pauper widows and orphans, might have been economized for the country.

But there are other lessons which have been taught, if not to the scientific world, to the public at large, and to those who take upon themselves the duty of instructing the masses through the medium of the periodical general Press. Regarded as a philosophical question, and examined by the light of history, the cattle plague would appear to be one of those periodical calamities which have befallen mankind in all ages of the civilized world, and which in ancient times were frequently attributed to the wrath of an offended deity. Every classical scholar knows that the plot of Homer's "Iliad" turns upon the quarrel of Agamemnon and Achilles, arising out of the plague supposed to be inflicted by

Apollo upon the cattle of the Greek army, and afterwards upon the Greeks themselves, and which was allayed by compliance with the will of the God; and it is unnecessary to allude particularly to the records of sacred and profane history for authentic details of similar visitations. We have no desire to insist upon the existence of physical causes for these epidemics, for all theories invented to explain their origin have been equally unsatisfactory. We therefore leave any speculations of the kind to such learned Thebans as are permitted to ventilate their folly in the columns of the *Times* and other newspapers, only regretting that their lucubrations appearing in those pages are estimated at much more than they are worth, which is really nothing at all, and that by diffusing erroneous and groundless doctrines, they really effect an enormous amount of public mischief, and retard or prevent the adoption of useful measures.

All that we seem to know at present is that such visitations upon mankind, and upon the animal and even vegetable kingdoms, have been permitted at various periods by the scheme of Providence, and that drug medication offers but very small chances of success in curing individual cases. The great principle to be observed is to isolate the diseased bodies from those which are sound, and thus to arrest the progress of the contagion. While ordinary treatment, therefore, offers at best but a doubtful chance, prophylactic measures are of the greatest possible importance, and are of undoubted efficacy; but even now in the nineteenth century the members of the Medical profession find a difficulty in impressing this truth upon persons in authority, either in the senate, among the press, or in the general public. The homœopathic quacks, and the advocates of the onion-and-garlic treatment, have all had a fair opportunity of trying their hands in the suppression of the cattle plague; and if the Medical Profession has no triumphs to record, it has no false pretensions to withdraw, and it may at any rate affirm, that from the first it foresaw the danger, and at the earliest possible period recommended the only available means of diminishing the mortality—namely, preventing the spread of the disease.

THE PLEA OF INSANITY IN CRIMINAL CASES.

A CASE of murder has just been disposed of at Brighton, which has terminated in a verdict of guilty, and a sentence of death, after an ineffectual attempt to procure the prisoner's acquittal on the ground of insanity. The facts of the case were plain enough and were not disputed, the accused having deliberately shot his sister-in-law with a revolver loaded with four bullets, two of which he fired into the body of the deceased, and then threatened to shoot with the other two anyone who attempted to arrest him. Nevertheless the attempt was made, and the capture was effected, fortunately without further bloodshed, and under circumstances most highly creditable to the captors. It appeared that the prisoner had led a most irregular life, being in the habit of drinking large quantities of spirits, which however did not make him drunk, although he had attacks of delirium tremens. When he was

in prison and deprived of the use of spirits, it was shown that he was perfectly quiet. It seems, therefore, that the paroxysms of violence which he exhibited were due to the excessive use of ardent spirits, and the law very justly holds that crimes committed under such circumstances are punishable. But it also appears that he gave abundant intimation to those around him of his murderous intentions, and that, although infuriated by drink or by delirium tremens, he was allowed to carry with him loaded firearms. A great amount of evidence was adduced to prove the man's outrageous and dangerous behaviour, as well as his wasteful, destructive, and extravagant disposition. We have no desire to offer any excuses whatever for the conduct of such a person, or to save him from the fate which awaits him; but we would humbly inquire whether society ought or ought not to be protected from the acts of such a person, whose ferocity has deprived one innocent person of life, and very nearly sacrificed a second victim. The *Times*, as is its wont, sings an *Io Paxan* that this criminal is to be hanged, and shows what a deterrent effect capital executions exercise over persons of similarly brutal propensities; but its illustration of Forward's case is an unlucky one, for Forward was hanged at the end of December, and the Brighton murder, which is admitted to be an analogous crime, was committed a month afterwards. It is quite evident, therefore, that Forward's fate did not deter the Brighton murderer from the accomplishment of his purpose. But we consider it a very great pity that the law, which prescribes the hempen rope for murder, does not endeavour to prevent the commission of that crime. Here is a man who is allowed to commit the most extravagant and dangerous actions, to carry about with him loaded weapons, and whom the Law and the *Times* newspaper declares to be perfectly in his senses, but who at last commits a murder and is duly sentenced to be hanged. This consummation may satisfy an "idea" of abstract justice, but it cannot recall the dead to life; and we are very doubtful whether it exercises any deterrent effect whatever upon persons with similar murderous propensities.

THE ST. PANCRAS WORKHOUSE INFIRMARY.

THE public mind has again been horrified by one of these occurrences in a Metropolitan Workhouse Infirmary, which have lately figured so prominently in the general newspapers. The penny-a-liners of the daily journals must, in fact, be making a capital harvest just now, because workhouse abuses are abundant enough, and as luck will have it, the papers find it to their interest to publish them; so that details which would have formerly been contemptuously flung into the waste-paper basket, are now willingly accepted and eagerly read. The last article in the "sensation" line has been the laying out of a poor little helpless illegitimate infant in the St. Pancras Workhouse, before it was dead, and although no great harm was done, as the child did die soon afterwards, yet the circumstance attracted the notice of a clerical gentleman who is called, we know not why, an "Evangelist," and who, having observed the circumstance when visiting the workhouse, forthwith reported it to the Poor-law Board, and the story, somehow or other, was published in the *Times*. The whole subject has been now thoroughly investigated, and only awaits the decision of the Poor-law Board; but the inquiry has revealed the state of affairs in the St. Pancras Workhouse, which will strengthen the

hands of those who are promoting a reform in this and similar establishments. The indefatigable Mr. Farnall, C.B., had a capital opportunity of baiting the Medical Officers of the Workhouse, and he amply availed himself of the chance. It appeared that the Medical Officers had not visited the deceased infant from the Monday until after its death on Thursday, and that they had not entered the children's nursery for a whole week previously. It also came out that, although wine and milk were ordered for the infant, no written memorandum was made of the orders; and it was very doubtful whether either of these articles had been given; and it was shown that the execution of medical orders was intrusted to pauper nurses. Without in any way presuming to give any opinion upon the manner in which the medical duties are carried out in the St. Pancras Workhouse Infirmary, we may observe generally that the Medical Officers are enormously overworked, and it is only lately that one of them died from fever contracted in the discharge of his duties. But it is a safe game to make the Medical Officers the scapegoats to answer for the defects of a bad system, and the opportunity of doing so is never thrown away by the Poor-law Board.

CHANGES IN THE EXAMINATION SYSTEM IN IRELAND.

OUR advertising columns to-day announce two highly interesting and important alterations in the present system of Examination for Medical Qualifications in Ireland, which, we think, cannot fail to meet at the same time the wishes of the student and the requirements of the profession. The Royal College of Surgeons has hitherto retained a system peculiarly its own, of examining each candidate for its Diploma separately on two separate days, for two hours each day. The interviews of each student face to face with his seven Examiners, was an ordeal which few candidates, however confident in their own attainments, could anticipate unmoved, and while the system entailed vastly greater labour on the Examiner, it did not afford any special security for the candidate's proficiency. By the ordinance which we publish to-day, the Council have resuscitated one of their bye-laws which had fallen into disuse, and have established two separate Sessional Examinations for which students can present themselves at stated periods, and the passing of which will qualify for the Licence of the College. The subjects of these Examinations are stated in the advertisement, and are arranged so that the objects of study may be taken separately. We congratulate the Council on the adoption of this system, from which we anticipate many good results, not the least important being to remove from the minds of individual students the very unjust impression that they may be dealt with with exceptional severity, or in any respect differently from their fellows.

Our readers will see from the second advertisement that the College of Physicians, following the example of Trinity College, has abolished examinations in the French and German languages, and has substituted for them English History and Modern Geography in the Preliminary Arts Examination. The necessity of a moderate acquaintance with the modern languages, in the case of any reading medical man, is so great in the present day, that, at first sight, the alteration above noted may seem injudicious; but we are informed that it was made for this reason—that, while the students

will, for their own advantage sake, acquire the modern languages, they will not have the same inducements to acquire the no less necessary but equally important parts of a liberal education. In other words, many a student will learn French and German, who will not voluntarily learn geography and history. The Examiners for 1866 are: In English, Dr. Steele; in mathematics, Dr. Ringland; and in classics, Dr. Belcher—all Fellows of the College.

BILLS FOR THE IMPROVEMENT OF THE DWELLINGS OF THE WORKING CLASSES.

THERE is no subject which is at present attracting in a greater degree the attention of sanitary reformers than the measures to be adopted for the improvement of the dwellings of the humbler classes, as is evident from the fact that there are now two bills for the object before Parliament, with every prospect of becoming law.

The first brought in by Mr. CHILDERS of the Treasury, the CHANCELLOR of the EXCHEQUER, and Mr. BRUCE, is entitled the "Labouring Classes Dwellings Bill," and is an amendment to the similar measure passed in 1851.

It provides for the granting of loans to any corporation, company, or estated person for the erection of such dwellings, the interest being 4 per cent., and the sum to be repayable within 30 years. The measure passed through committee on Thursday last, but not before Sir C. O'LOGHLEN, watchful of the interests of his country, obtained a promise that the advantage of the Act would be extended to Ireland "in a bill which the Government was about to introduce for amending the Public Works (Ireland) Act."

The second act was introduced by Mr. M'CULLAGH TORRENS, Mr. LOCKE, and Mr. KINNAIRD, and is less of a permissive nature; indeed, under flagrantly unsanitary circumstances, it is compulsory. It proposes that, if the death rate of any town for three successive years shall exceed 30 per 1,000, on petition of 20 ratepayers the Home Secretary shall send an inspecting architect to examine the state of dwellings of the humbler classes, and to report on the repairs necessary to render them habitable and wholesome, or whether they require to be altogether removed.

This report shall be sent to the local authority, and by it published; and if it cannot be shown that the repairs are unnecessary, the Home Secretary shall order the local authority to execute them within a reasonable time.

If any houses require to be demolished, they are to be replaced by dwellings fitted with sanitary requirements, and affording 350 cubic feet of air space for each inhabitant.

For such purposes the Loan Commissioners are to advance sums at the low interest of $3\frac{1}{2}$ per cent., to be repaid within 30 years from the borough rates.

When it is remembered that improved dwellings have paid as much as 14 per cent. on the capital expended in their erection or renovation, a gain instead of a loss to the borough fund may be expected, especially as the rate of interest is so low. The bill further pro-

vides for the taking of land for sites and houses due compensation being granted to the owners, and for investing the ownership and management of the dwellings in the local authority, who may appoint officers and make by-laws. One of such by-laws must prohibit subletting by the occupier of a separate tenement, for in this way the evil of overcrowding—which it is the object of the bill to prevent—would be reproduced.

The bill has been sent to a special Committee, consisting of the following members:—Mr. TORRENS, Mr. GOSCHEN, Mr. KINNAIRD, Mr. LOCKE, Mr. HUGESSEN, Sir C. O'LOGHLEN, Mr. M'LAREN, Mr. AKROYD, Mr. ABEL SMITH, Mr. HENLEY, Lord R. MONTAGUE, Mr. ADDERLEY, Sir M. FARQUHAR, Mr. GRAVES, and Mr. GREENE.

It may be trusted that the members for Edinburgh, Liverpool, and Halifax, as well as other members of the committee, will not allow the enactment of any clauses which are not necessary for the preservation of the public health in towns where a frightful mortality shall have prevailed for three years, or any which would unfairly bear upon the ratepayers.

The distinctive feature of the bill, and that wherein it is truly valuable, is that it will render it *incumbent* on local authorities to effect the improvement of the homes of their working populations, and not merely *allow them* to do so, if so disposed, which the Government Bill provides for.

Public bodies in Scotland have petitioned for the extension of the "Artizans' and Labourers' Dwellings Bill" to that country, and we think our Medical corporations and the Municipal councils of Dublin, Cork, Belfast, Waterford, and other large towns are called upon to do likewise. The corporation of the last-named city has already the credit of having procured promises of improved legislation for this country in regard to lodging-houses and the removal of nuisances.

DUBLIN HOSPITALS OF THE HOUSE OF INDUSTRY.

On Friday last the election of a physician to these important hospitals took place, in order to fill the vacancy created by the retirement of Sir Dominic Corrigan, Bart. As a partly incorrect version of this election has already appeared in one of the local newspapers, we deem it right that the facts should be placed before the profession.

There were three candidates, all well and favourably known practitioners in Dublin:—Drs. Lyons, Frazer, and De Ricci.

The voting was as follows:—Dr. Lyons, 5; Dr. De Ricci 3; Dr. Frazer, 1.

Dr. Lyons was accordingly declared elected.

We congratulate the public, the profession, and the hospitals in question, on the election of Dr. Lyons to this office, for which he has every requisite of an accomplished physician. Himself a man of academic education; a fellow of his college; an hospital physician of standing; a well-known and well-read author; an examiner in medicine in two collegiate bodies, and a medical lecturer in a third; he needs no commendation, save that to which true merit and hard work justly entitle him. He will be found "*aptus moribus*" by his colleagues; and as to the general issue we say "*quod bonum, felix, faustum que sit.*"

THE CONVERSAZIONE OF THE OBSTETRICAL SOCIETY OF LONDON.

THE Conversazione of the Obstetrical Society of London, and the Exhibition of Obstetric Instruments, will be held this evening, March 28, at the Royal College of Physicians. The contributions already received are, we understand, very numerous, and several eminent obstetricians from Russia, Germany, France, Italy, and other parts of the Continent, have signified their intention to be present. To-morrow (Thursday) the foreign professors attending the *soirée* are invited to a dinner at Willis's rooms, at which it is expected that a large number of the Fellows of the Obstetrical Society and others will be present.

MEDICAL COUNCIL PUNISHMENTS.

THE following are the names of the delinquents who have been struck off the Medical Register, a list of whom has been delivered to all Medical Examining Boards, in order to prevent a re-examination and obtaining other qualifications, viz.:—

Abercrombie, Robert, well-known in connection with the notorious Strand Museum.

Barrett, John Carter, having been convicted of felony.

Barton, John, his name erased, "having been fraudulently or incorrectly made."

Broatch, John, for having obtained the entry of his name by a false declaration.

Brown, Hugh, his diploma having been obtained by a false statement of his age.

Cumming, William John, having been convicted of felony.

Dougal, Daniel, his diploma having been obtained by a false statement of his age.

Gomley, Daniel de la Cherris, having been convicted of a misdemeanour.

Jordan, Robert Jacob, of the notorious museum in George-street, Hanover-square.

Jones, David Griffiths, having been convicted of a misdemeanour.

Kearney, John, for "infamous conduct in a Professional respect."

La Mert, Samuel, "for infamous conduct in a Professional respect."

Organ, Richard, "for infamous conduct in a Professional respect."

Protheroe, John Edward, the entry of his name "having been fraudulently obtained."

Thomas, Evan, having been convicted of perjury.

Whalley, Thompson, having been convicted of a misdemeanour.

Wrixan, Robert, having been convicted of perjury.

It is stated that other names will be submitted at the next meeting of the General Medical Council for removal from the Register.

HOSPITALS FOR NATIVES IN ALGERIA.—The Emperor of the French has just directed that the subscription which had been opened to erect a monument in commemoration of his journey to Algeria with the Empress in 1860, should receive another destination. The money is to be employed in creating in the hospitals a certain number of wards for the reception of Arab patients exclusively. These measures are being carried out at Algiers, Constantina, and Bona.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—At the meeting of this Society, held on Tuesday, March 13, in the Hall of the Faculty of Physicians and Surgeons, the following gentlemen were elected office bearers for the present year:—*President*: Dr. Allen Thompson. *Vice-Presidents*: Dr. Robert Paterson; Dr. John Coats. *Council*: Dr. Naismith, Hamilton; Dr. W. T. Gairdner; Dr. Yeaman; Mr. Robertson, Renfrew; Dr. Dewar; Dr. Tindal. *Secretaries*: Dr. James Adams; Dr. Robert Perry. *Treasurer*: Dr. Howatt.

Correspondence.

✂ We are not to be assumed to agree with the views of our Correspondents whose communications we insert for the purpose of affording opportunity for the enunciation of all shades of opinion in things medical. Our revision of letters is, therefore, confined to the removal of statements or expressions which we consider unsuitable or irrelevant to the subject in hand.

THE VALUE OF ALBUMINOUS URINE AS A DIAGNOSTIC.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Among the many fallacies and exaggerations in the practice of medicine, I do not know one more hurtful than the undue importance which is now attributed to the occasional presence of albumen in the urine, or albuminuria as it is called. As for myself, I have ever considered the exit of albumen to be analogous to vicarious hæmorrhages, which denote totally opposite characters in the system, both sthenic and asthenic. Of the former, a good example may be found in pneumonia, and of the latter, the bleeding from various organs in the latter stages of severe small-pox, of fevers, and of scurvy; and therefore in the treatment of disease, the presence or absence of albumen has never deterred me from combatting the more salient symptoms that have shown themselves. Where albumen has escaped in large quantities or is of long continuance, the patient, as I have found, becomes exhausted, suffering also from great thirst; in fact, very similar to those who have suffered from severe loss of blood, or exhausting diseases, as diabetes. I have not myself had the time or inclination to analyze the urine of the patients—it would be, in my opinion, to prove a negative. Those who attach so much importance to albumen ought to have satisfactorily proved that its presence in the urine *invariably* indicates the granular kidneys or disorganization of the system. A friend of mine who followed the teaching of his professors in this respect for some years till a most erroneous prognosis that he gave, on the detection of this albumen in urine, induced him to carefully investigate the subject; and he has assured me that he often finds it in cases of totally diverse natures, that it is often present one day and absent the next, and that it ceases to escape altogether, and that he concludes that the mere presence of albumen in the urine, without other symptoms, does not indicate organic disease or a breaking up of the constitution.

I will briefly relate two cases in which the presence of albumen in the urine was the entire foundation of the treatment, to the exclusion of other far more important indications. One who had severe congestion of the lungs with spitting of blood; this patient was relieved by antimony and the usual remedies. Another in a patient who might be fairly termed an athlete, and who up to the time of his attack (pneumonia) had been engaged in occupation requiring a large amount of bodily and mental exertion. This gentleman had never been seriously ill; whatever deviations from health he suffered from had been of a sthenic and part of an asthenic nature; his condition of body was excellent; he neglected himself and would not submit to the necessary treatment to reduce inflammation; the consequence was effusion into the ventricles of the brain. I proposed to use mercurial frictions, believing that if the patient lived long enough for the mercury to act it would afford a good chance for the absorption of the fluid. An eminent hospital physician was called in, who, on applying a test for albumen in the urine, and succeeding in detecting a small quantity, at once protested against the use of mercury. He could suggest no remedy at all likely to cause absorption of the fluids but a blister and aperients. As it was a matter of great doubt whether the patient could survive long enough for the

mercury to act and other reasons, I reluctantly acquiesced, and had the mortification to see the case terminate in death in thirty hours after the consultation, feeling assured that no adequate measures had been adopted for the removal of the fluid.

It may be fairly asked what can be the difference between a learned physician who thus acts, and the water doctors who were in vogue about a century and a half ago, and who were learned quacks? Indeed is there much difference between them and Sangrado, the creation of Le Sage to illustrate the narrowness of views of physicians in his day; and surely physicians who close their eyes to obvious facts and adopt one particular view merely because it is in vogue, are equally as absurd as Sangrado, who could only think of bleeding and warm water. There is an anecdote related of a physician who, on a tailor's wife bringing a bottle of her husband's urine for the purpose of his prescribing for him, sending a bottle of his own, and telling the wife that it was as reasonable for him to expect her husband to make him a coat by the examination of his urine, as it would be for him to prescribe by that alone.

It is far from my wish to undervalue the importance of the indications shown by urine and other excretions; my only object is to induce practitioners not to trust solely to one symptom; and I feel assured it would well repay the trouble if practitioners who have time and opportunities were to investigate this subject, and I doubt not but that they would arrive at the same conclusion as my friend has done, that albumen may be often present in the urine without organic disease in the body, and that to give too much importance to its presence is likely to lead them into serious errors.—Yours, &c. A PHYSICIAN.

THE FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I quite agree with "A Militia Surgeon," who wrote on the Fellowship in last week's impression, "that the highest position in the College should be thrown open to a certain grade in the profession;" but the determination of the characteristics of this grade is a most important question, on which I have hitherto been silent, because I felt that there were many other Fellows far better entitled to speak than I.

Everything which has as yet been published on the subject has been in favour of doing away entirely with an examination, and conferring the Fellowship on the following grounds—viz. :—

- 1st. The number of years spent in practice.
- 2nd. The payment of £20 or more.
- 3rd. Professional character.
- 4th. Moral and social reputation.

Now, let us for a moment conceive these conditions to have become law—a candidate applies; the first and second conditions are easily settled, but how as to the third and fourth? Who are entitled to judge, and who will do it? Plainly none but those professional men amongst whom he lives and practises; but which one of those will be bold enough to give any but a most favourable report of his professional, moral, and social character? If any one did so, he would expose himself either to the charge of having acted on professional jealousy, on the one hand, or an action at law on the other; hence, as a rule, every man who had spent a certain number of years in practice and could pay £20 would be entitled to the Fellowship, although perchance those twenty years have been spent in a species of professional or social vegetation which has just saved him from reproach, while many of his brethren have gone to their long home worn out at an early age, perhaps, by their efforts to benefit their fellowmen and the profession of their choice;

but efforts, alas! which their College had refused to reward because they had not lived long enough.

If all feelings unworthy of so grave a subject be cast aside, I cannot think that the voice of the Fellows of our Irish College will be in favour of such a course. I, for one, would not think of retaining the Fellowship under such circumstances. Indeed from what has been already written on the subject, the junior Fellows are placed in a very anomalous position, as they have been plainly told that hitherto the Fellowship has been conferred on a wrong class of men—viz., those who have been barely five years in practice and have passed a strict practical examination. Amongst this class my name appears. I procured the Fellowship in 1863, after five years' steady work (for I had always kept the Fellowship before me as a reward for industry in practice), and an expense of nearly fifty pounds. In the name of my junior brethren, in the services and at home, I ask our college to reflect and be just to her junior Fellows before she is generous to her senior Licentiates.

The sale of over two hundred and thirty Fellowships in 1844, to any one having any surgical qualification, has been a blot which Time only could wipe away. He has nearly done his work, and the Fellowship will ere long have recovered from the blow, which has been the *real cause* of so few having sought its honours since. Let us beware how it receives another even more disastrous. If the senior Licentiates are anxious to become Fellows, let an examination of such a practical character (on the operating table and in the hospital) be instituted as will entail no further study than a good surgeon's every-day practice requires, and no more dexterity than any man entitled to call himself a Fellow of a College of Surgeons (especially our Irish one) should possess. Or if the College wishes to confer a mark of distinction on age and literary attainments in an exceptional case, let an honorary Fellowship be bestowed; while the examination for those five years and upwards in practice remains as before, or is made more practical.

By these means the Fellowship of the Royal College of Surgeons in Ireland will remain a title which an honest man will not hesitate to assume, while no injustice will be done to men who otherwise may feel it right to resign a title which, by close practical study, a severe examination, and no small cost, they thought they had won for life.

I am, Sir, yours very truly,

H. R. HADDEN, F.R.C.S.I.

Clonakilty, March 22, 1866.

INDOOR CLOSETS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Believing that you require but a very slight apology for troubling you on so important a subject (which I now beg to offer), I venture to address you with reference to the important letter of Dr. Henry MacCormac, in your impression of the 31st ult.

First,—Considering it absolutely necessary as the preliminary step on the subject of "health of towns," that the urine should be kept as separate as possible from the fæces, I have in every house I have occupied in this country contrived to effect this object completely by erecting the out-door privies on sloping ground, thereby leaving the former rapidly to be evaporated and absorbed, and the latter hardening in a few hours, so as to be removed to a distance and used for gardening purposes. Our in-door closets have pipes leading down to a similar sloping ground; but where natural sloping ground is unattainable, it might very frequently be made artificially, I conceive; and the further contrivance of fitting a piece of board in common privies lengthwise under the seat, to go low down, so as to let the urine run down into a receptacle by itself, and the fæces to fall down on the other side into another separate receptacle by itself—a similar

arrangement being practicable for indoor closets, I am led to believe.

I at the same time beg leave to mention, in regard to ventilation referred to by Dr. MacCormac, the very good effect of fitting bedroom windows with portable *buntin* covered frames (at a cost of less than 1s. each), which my friend Dr. T. Caddy, R.N., recommended for the purpose. They freely admit as much fresh air as required, while their outsides are found often saturated by the dampness or moisture which could not penetrate through the *buntin*.—I am, Sir, your most obedient servant,

W. H. BROWNE, J.P.

Antigua, 27th February, 1866.

ON CATTLE PLAGUE, ITS PREVENTION AND TREATMENT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I do consider that well-timed and moderate ventilation, and the use of iodine as a disinfectant, in the byres of owners of stock, are highly necessary and serviceable where the cattle rinderpest prevails. And to those which I formerly suggested in your journal, I may add two other medicines—viz., henbane and nux vomica, in suitable and proportionate doses for the disease, in its second or low stage; and in the intervals warm drinks of flour-meal gruel and strong sweet ale, given three times a day at least, with external mustard poultices to breast and neck repeated until relieved.

G. K. H. PATERSON, L.R.C.P.L., L.R.C.S.Ed., &c.

Balbeggie, Perth.

TRIPLETS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—An interesting case of the above having occurred in my practice last week, I will feel obliged if you record it in the next issue of your widely read journal.

About eleven o'clock on the morning of the 13th inst., I was called on at the workhouse to visit the wife of Sub-Constable Keeshan, about six miles from this, who, the messenger stated, was in labour for the last three days, "that one child was born at four o'clock the preceding day, and that the midwife suspected she had another child." I proceeded at once, and on arriving at the residence of the patient went to her room. I found a very pale, delicate, and anæmic woman, lying on her back, the "old woman" holding the funis untied since the birth of the first child. Having placed the patient in the usual position, I made an examination, but could not make out the presentation. It was not a head or breech, but I could feel ribs through the membranes, yet unbroken and high up. I at once ruptured the membranes and delivered the infant, the uterus assisting as soon as I got the breech into the hollow of the sacrum. So soon as the infant was expelled, I passed my left hand over the abdomen to feel the state of the uterus, and was more than surprised to find a third child still in utero. Having tied the funis and separated the infant, I at once made an examination but could feel no presentation. I passed my hand into the uterus, and having ruptured the membranes I turned the child, and with great difficulty delivered the infant, which was very large. There were two large placentas which I had to remove. As there was a disposition to hæmorrhage, I put on a large pad and binder, and gave stimulants. The children are strong and healthy, the first and last larger than the second—two females and one male.

I reported this case in the proper quarter, and got on yesterday from the "Keeper of the Privy Purse," the usual Queen's donation of £3, to assist the mother after her confinement of three children at one birth." This woman, Mrs. K., has now eight children, the eldest under ten years—that is ten in family living on something over £2 per month. I had a case of twins within the month in the same locality; mother

very small and weak, children large and strong.—I am, dear Sir, yours very truly,
 THOMAS BURKE, M.D.,
 Sheriff, March 23rd, 1866. Medical Officer, Workhouse, &c.

FEES TO MEDICAL WITNESSES IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Perhaps you may consider the enclosed communication worth a place in your next issue.—I am, yours, &c.
 W. O'NEILL.

Mitchelstown, March 23, 1866.

[Copy.]

"Dublin Castle, 19th March, 1866.

"SIR,—I am directed by the Lord Lieutenant to inform you, in reference to your letter of the 14th instant, that Mr. Gilman, Crown Solicitor, has been instructed to pay you two guineas—£1 1s. for medical examination of Juliana McCarthy, charged with infanticide, and £1 1s. for attendance at Petty Sessions in the above case.—I am, Sir, your obedient servant,
 THOS. LARCOM.

DR. RICHARDSON ON LOCAL ANÆSTHESIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Richardson has done me the honour to notice my communication on the subject he has brought before the profession. I am glad to find that his instrument has not been patented; my information to that effect was derived from the instrument-maker to whom I applied here, in the first instance, for the necessary apparatus. I was obliged at first to use Dr. A. Clark's spray producer for the larynx, and I found it answer very well. I have since used Dr. Richardson's own instrument and found that they are equal in their performance as far as a single jet is concerned; but I now see with Dr. R., that the little glass instrument which I have used is incapable of adaptation for a compound jet. If any one will try to produce the effect just short of the freezing point, and then prick the part with anything sharp, he will find the phenomenon which I have alluded to—viz., the sudden accession of the blanching due to the freezing of the tissues. I operated on myself and on one of my pupils in this way, pricking the hand with a brass pin, and I found that a considerable amount of inflammation followed; in two days the part presented the same appearance as a burn of the second degree; and even now I can show the mark on my hand produced in the above way on the 24th February. I argued, that if this was the effect produced on sound skin, what would be the effect produced on a raw surface; and I ventured to suggest the use of chloroform in this latter instance, as having an anæsthetic property of its own, independent of that caused by rapid co-operation: it would be less liable to do mischief. I have operated now on several cases, and find that Dr. R.'s method gives the patient complete immunity from suffering, if applied with proper precautions in those cases suited for it. At the first operation for phymosis in which I assisted, the patient complained of a good deal of pain, as the incision was performed too rapidly; since then I have performed this operation painlessly, but I occupied nearly five minutes in the removal of the prepuce. No matter what instrument is used, the principle remains the same; and it is to the researches of Dr. Richardson that the public are indebted.—I remain, your obedient servant,

GLASCOTT R. SYMES.

7, Hume-street, Dublin, 24th March.

NOTE FROM EBEN WATSON, M.D.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—You have published in your columns two papers of Dr. Morell Mackenzie's against me, and only one of mine in reply. I therefore sent you a second article which I thought was of scientific interest, at least equal to its predecessors, but in that you differ from me, and I bow to your decision.

I have, however, neither time nor inclination to put my ideas in any other shape for your journal, and therefore the

controversy must stop, so far as I am concerned. Indeed I have been advised by friends, both in London and in Glasgow, that it is unnecessary for me to continue it, as my statements have commended themselves to the truth-lovers of our profession, while those of Dr. Morell Mackenzie are easily estimated at their proper value.

For the rest I have little concern—I can afford to smile at his personal vituperation of me, though I must say it was both very needless and very rude.—Your obedient servant,
 EBEN WATSON.

2, Newton terrace, Glasgow, 23rd March, 1866.

Parliamentary Intelligence.

HOUSE OF LORDS.—MARCH 20TH.

Earl GRANVILLE, in reply to questions by the Duke of Montrose and the Duke of Marlborough, said the order of Council allowed healthy cows to be moved a limited distance in the metropolis with a licence. With regard to the effect produced by the stoppage of the movement of cattle by railway, the Government had been overwhelmed with complaints on the subject, and he was of opinion that the prohibition could not be long continued. It was intended to allow the carriage of cattle by railway in certain districts, and under certain restrictions, so as not to come into contact with the cattle plague. Notice would be given of these changes, and the existing prohibition would be enforced until the new order came into operation. The Government intended to bring into the House of Commons this day a Bill to confer enlarged powers upon the Privy Council.

HOUSE OF COMMONS.—MARCH 15TH.

CATTLE CONTAGIOUS DISEASES.

Colonel EDWARDS asked whether it was the intention of her Majesty's Government to introduce any permanent measure for the prevention of contagious diseases among cattle, and whether the Orders in Council now contemplated were, under any legislative enactment, to be submitted within any given time for the consideration of Parliament.

Sir G. GREY replied that it was very important to have a permanent Bill, similar in principle to the Government Bill, for the purpose of checking the spread of contagious diseases among the cattle, chiefly in respect to those which were brought to this country and their removal into the interior. The Government had not yet had time to consider the subject sufficiently to enable them to frame a Bill, and probably the better plan would be to submit the matter to a committee before any measure was brought into Parliament. The Orders in Council would be laid before Parliament—the Act of Parliament rendering this imperative.

CONTAGIOUS DISEASES BILL.

Upon the motion of Mr. CHILDERS, leave was given to bring in a Bill for the better prevention of contagious diseases in certain naval and military stations.

MARCH 16TH.

FLOGGING AND BRANDING IN THE ARMY.

Mr. TAYLOR moved an address for returns of the number of men flogged in the army and militia of Great Britain and Ireland in the years 1863, 1864, and 1865 respectively, specifying the offence, the regiment, the place of station, whether at home, in India, or the Colonies, the sentence, and the number of lashes inflicted on each person; and of the number of men marked with the letter D or with the letters B C during the same years.

Agreed to.

MARCH 19TH.

MORTALITY OF TROOPS IN CHINA.

Colonel NORTH gave notice that to-morrow he should move the appointment of a Select Committee to inquire

into the mortality among the troops in China and the causes which led to it, and the conduct of the department of the Government whose duty it was to administer to the wants of those troops.

MEDICAL OFFICERS.

Colonel NORTH asked whether it was the intention of Government to carry out the recommendations as regarded increased pay, &c., of the committee which was appointed to inquire into and report upon the grievances of medical officers of the army and navy.

The Marquis of HARRINGTON said the report had only been received a short time since, and it was impossible at present to state how far the recommendations of the Commissioners would be carried out.

Colonel NORTH said he would repeat the question after the recess.

MARCH 20TH.

DISEASE IN SHEEP.

Mr. B. COCHRANE asked what rules were to be applied to Scotland with respect to the slaughter of infected sheep. It was stated the other night that the same rule would apply to sheep as to cattle; but if that were so, what would take place if the rinderpest broke out on a large hill farm?

Sir G. GREY said if the hon. gentleman would refer to the Act he would see that it directed the slaughter of all infected animals.

Mr. COCHRANE wished to know whether, if on a large farm the disease should break out, the inspectors would have the power of ordering the slaughtering of any number of sheep.

Sir G. GREY said the hon. gentleman should have put the question when the Bill was under discussion. The interpretation of the Act was not left to the Government, but to the judicial authorities.

TRANSIT OF CATTLE BY RAILWAY.

Mr. READ asked if the transit of cattle by railway would be prohibited after the 24th of March.

Sir G. GREY thought that it would be desirable to continue the prohibition until the issue of the general order in council which was now under consideration. It would probably not be issued in time to come into operation on the 25th inst. Some time should be allowed in order that its effect might be generally known.

MORTALITY OF TROOPS IN CHINA.

Colonel NORTH moved for the appointment of a select committee to inquire into the mortality among the troops in China.

Sir H. VERNEY and the Marquis of HARTINGTON agreed with Colonel North's motion, which was then carried.

MARCH 21ST.

SHEEP, ETC., CONTAGIOUS DISORDERS PREVENTION ACT AMENDMENT.

Sir G. GREY obtained leave to bring in a Bill to amend the Act of 11 and 12 Vict., cap. 107, to prevent the spreading of contagious or infectious disorders among sheep, cattle, and other animals.

MARCH 22ND.

FRESH OUTBREAK OF THE CATTLE PLAGUE IN LONDON.

The Earl of LICHFIELD asked his noble friend the President of the Council whether it was true that the Cattle Plague had been reintroduced into several parts of the metropolis by means of a cargo of animals imported from Holland.

Earl GRANVILLE—I am sorry to say there is no doubt whatever that within the last day or so a cargo of Dutch cattle arrived, affected as the noble earl has stated. I am told that the disease was not sufficiently visible, being only in a state of incubation, and that the Custom-house authorities did not detect its existence, but admitted the cattle into the metropolis. I may add that information having been received yesterday by the Secretary of State for Foreign Affairs that proper precautions were not

taken in Holland for the prevention of diseased cattle coming to this country, Her Majesty's Ministers have asked Her Majesty to appoint a Council to be held this week with a view to the issue of an Order prohibiting the importation of cattle from Holland until further notice.

Lord DENMAN urged the Government to establish a dead meat market. He was sure it would cause no inconvenience to the trade, and would tend much to prevent the spread of disease among the cattle.

VACCINATION BILL.

On the order of the day for going into committee on this Bill,

Mr. BRUCE begged to postpone the committee until the Wednesday after the Easter recess, but he wished to take that opportunity to remove a misapprehension which had created a great deal of alarm, and that was, that re-vaccination was made compulsory by the Bill. That was not the case. The object of the Bill was to remove a doubt whether the public vaccinator could be paid for re-vaccination, and it would enact that if any person desired to be re-vaccinated the public vaccinator might receive two-thirds of the ordinary fee for his services.

The committee was then postponed.

CONTAGIOUS DISEASES BILL.

Lord C. PAGET, in moving the second reading of this measure, explained that it was intended to renew an Act passed in 1864 for the health of our soldiers and sailors in the various ports, with additional powers recommended by a committee of medical men. It was proposed to refer the Bill to a Select Committee.

Mr. HENLEY described the measure as a very queer Bill upon a very queer subject. Its object was to preserve the health of Her Majesty's troops, and its endeavour was to remove all the penalties which a higher Power had imposed upon sin, and to give the opportunity of sin without the punishment. He must appeal to the Chancellor of the Exchequer whether they could expect any blessing upon their legislation if they took these unhappy women, freed them from disease, and then turned them loose to follow the same wretched courses, without any attempt to reclaim them. Inspectors were to be appointed for their bodies, but it was not proposed to take any advantage of the opportunity afforded by the curing of disease to induce them to lead a better life on their discharge. The principle of the measure had been in operation since the middle of 1864, but its effect did not appear to have been very satisfactory, for in the last report on the navy the medical gentlemen made the following note:—"Little or no diminution of disease in the home ports on account of this legislation." He regarded this legislation as vicious if unaccompanied by any attempt at reclamation, and he hoped the right hon. gentleman would introduce in committee provisions with that object.

Mr. AYRTON said his objections to the measure were still stronger than on the introduction of the original Act. Even in France a flimsy veil was thrown over these proceedings, by the suggestion of something being done to reclaim these unhappy creatures, but in this country the Government assumed no cloak of decency or morality by proposing anything for their benefit. It was simply a Bill for keeping public women at the public expense for the gratification of our soldiers and sailors.

The CHANCELLOR of the EXCHEQUER observed that it was hardly possible this subject could be discussed then with the fulness which would be desirable. His noble friend, in proposing the second reading of the Bill, had merely proposed the continuation of a system which had received the sanction of Parliament. Neither his noble friend nor Her Majesty's Government was desirous of flinching from a full consideration of the numerous difficulties by which this matter was surrounded; and the noble marquis had announced his intention, at the proper time, to propose that the Bill be referred to a Select Committee. It would be desirable that those gentlemen who had charged themselves with the painful duty of looking

into this question should serve on that committee. They wished the matter to be examined free from prejudice of any kind. He therefore hoped there would be no objection to having the Bill read a second time.

The Bill was then read a second time.

SCOTTISH REGISTRAR-GENERAL'S REPORT.

THE death-rate of the year, 225 in every 10,000 persons (in England 234), though much above the average, was lower than in the two previous years. In the towns the ratio was 274, in the rural districts 170. During the whole year the epidemic of typhus fever prevailed, but if it follows the usual three years course of epidemics it will die out with the setting in of the summer of this year. The mean temperature of the year, 46·9°, was nearly 1 deg. above the average—a result produced mainly by the high temperature of June and July, and more especially September. September was close, dry, and sultry, particularly in its first half, with little or no wind; and during the latter half of the month a thick mist, or fog, settled over the ground, favouring the development of mildew, which attacked the turnips to a large extent, while the Russian cattle plague spread over the country, but the mortality of the population was at its lowest rate. The natural increase of the population of Scotland, the excess of 113,126 births over 70,821 deaths, was 42,305, but 13,277 of the emigrants of the year were of Scottish birth, and the amount of the migration to England, Ireland, and the Continent of Europe is unknown. The Registrar-General has the satisfaction of reporting that small-pox almost disappeared from Scotland in the year 1865. The compulsory Vaccination Act came into operation in 1864, and in that year more than 95 per cent. of the children who lived long enough were successfully vaccinated under the Act. Of the residue 0·67 per cent. proved constitutionally insusceptible, in as many more instances vaccination was postponed, others had been vaccinated by clergymen or midwives, and the rest were lost sight of through removal. The deaths from small-pox in the year 1864-5 will not be known for many months, except so far as relates to the eight principal towns in which more than half the deaths occur, and there they fell from 816 in 1863 to 679 in 1864, and to 67 in 1865. But small-pox comes in epidemic waves; a very high wave flowed over the country in 1863, slightly falling in 1864, but attaining a very low trough indeed in 1865. We must wait to see to what extent the disappearance of small-pox from Scotland may be owing to unknown atmospheric influence. Scotland is not a country where vaccination was previously neglected; the great majority of the children were vaccinated either by a surgeon or by a midwife, or the clergyman. But it can scarcely be doubted that the general adoption of vaccination under the new Act has already had considerable effect in reducing the mortality, notwithstanding the proportion of adults who remain unprotected, and the allowance of six months before the vaccination of infants is required by the law. The payment of the medical fee under the Act is a very heavy burden to some classes.

LIVE CATTLE AND DEAD MEAT.

THE chief entrance to the filthy dead-meat market of the metropolis is so choke full of carts and horses, dogs, butchers, live cattle dealers, and dead cattle, that even the stout policemen can scarcely keep order among the surging mass of men and beasts, and have to work hard to prevent absolute riot. We notice here that the worst-behaved of the crowd are not the drivers of the railway vans, among whom there seems to be a fair amount of discipline, but the men in charge of a number of small carts, the meat of which is packed in queer-looking hampers, of no particular colour, and certainly not particularly clean. These men, we are told, are "Whitechapel butchers." It appears that the greater quantity of foreign cattle and sheep—amounting to no less than 2855 oxen, 323 calves, and 8847 sheep, or above 12,000 head, in the week ending Saturday last—which is imported from abroad is sent

into the mysterious regions of Whitechapel, there to be converted into meat. It is here, in Warwick-lane, not wide enough for two donkey-carts to pass each other, that we meet the tides of food supply for the great metropolis—the foreign tide from Whitechapel, and the railway-borne tide from Land's End, the Irish Channel, and John O'Groat's. Steam by sea and steam by land have carried the life sustenance of the three million inhabitants of London, thus far, with the precision of clockwork—it is not more than 12 hours ago since yonder waggon-load of prime beef left Scotland; but here, in this wretched lane, the whole wonderful system of traffic comes to an ignominious standstill. Is there anything more disgraceful to city management than this so-called metropolitan dead-meat market? The reply to the question which we ask ourselves, here in Warwick-lane, at 5 a.m., is in volleys of hideous oaths, worthy of Newgate. In his examination before the Cattle Plague Commissioners, Mr. James Allport, traffic manager of the Midland Railway, speaking modestly, declared that "to regulate the supply of meat for London from the country would involve an amount of organization which, much as railway men are accustomed to that sort of thing, he should shrink from." As far as we have been able to learn from our visit to Newgate-market, and inquiries made on the spot, we must say that the "railway-men" are certainly doing their duty, and, perhaps, more than their duty in this extraordinary emergency; but that the men to whom the local government of the metropolis is intrusted, the "fathers of the City" in the first instance, are shamefully neglecting their business. This dead-meat market at Newgate is nothing less than a public disgrace. Even before the breaking out of the cattle plague there were sent into that dark and dirty hole, dignified by the name of a market, not less than 120,000 tons of meat annually, or above five millions of pounds per week, and the quantity at present has probably tripled or quadrupled. From all the nooks and corners of these islands, and even from the farthest end of Europe, food is gathered to supply the wants of the greatest assemblage of human beings in the world, and when it has been gathered at so much trouble, and an infinite expenditure of skill and ingenuity, and after it has been carried to the very heart of the big city with marvellous speed, there is not so much as a decent shed to shelter the valuable stores. Oh, that but "railway man," so much abused in our days by philanthropic talkers, could take the matter in hand for a single year or even only a single month! For half a generation the "dismarking of Newgate-market" has been talked of in the City, and still there is nothing but talk. And there seems no likelihood that the thing will ever be done unless by one of our great public companies. The Great Northern Railway already has commenced market building, and others, we hope, will follow in the path. Nothing but a good market-place fit for the requirements of London is wanted to complete the revolution in the traffic from "live cattle" to "dead meat"—a revolution desirable in many respects, and one which will benefit the railway companies who carry dead meat instead of live stock to the London and other great markets of the country.—*Railway News.*

SCURVY AND ADULTERATED LIMEJUICE.

MR. C. J. CARTER, Coroner for Kent, last week resumed and concluded an inquiry relative to the death from scurvy of Henry Griffiths, one of the crew of the *St. Andrew's Castle*. The sufferings of the crew of this ship on her voyage home from Shanghai to London have already been made public. An inquest was held before Mr. Humphreys on the body of one of the men who died of scurvy in the Thames, and it was satisfactorily shown that the ship's provisions were good, and that the captain had done his duty with great humanity, not only towards his men, but in respect of a lady passenger who lost her reason during the voyage. Samples of the limejuice were handed round to the jury, and practical men pronounced it to be of good quality. Several of the crew were now examined, and they spoke well of the provisions on board, which were above the average quality. With respect to the limejuice, they stated it was excellent, and better by far than that usually served out on board ships, but they never took it unless they wanted it. Captain George McBane said that the *St. Andrew's Castle* was of 659 tons burden, and was a well-found vessel. They placed thirty gallons of limejuice on board in barrels. He served out half an ounce of it daily to each of the crew, and also three ounces and a half of sugar to be mixed with it. The men were,

many of them, prejudiced against the limejuice, it was so tart. It was not his duty to see the men drink it. Mr. Coleman, who appeared to watch the proceedings for the Board of Trade, stated, in answer to the coroner, that in the Royal Navy the men were called up at noon daily and made to drink the limejuice in the presence of an officer. It was mixed with rum. In the merchant service the captain was only bound to serve it out, not to see it swallowed. Captain M'Bane said he believed that what he served out was good limejuice. Mr. Harry Leach, medical officer on board the *Dreadnought*, said that the cases of scurvy brought under his care on the 16th inst., from on board the *St. Andrew's Castle* were the worst he had ever seen. The man Griffiths died the next day. He had analyzed some of the so-called limejuice from on board that ship. He was assisted by a chemist of high standing. They found that the fluid was not limejuice at all. It was either citric acid and water or weak lemonjuice and water, but they believed that it was merely citric acid and water. The mixture was quite inert and useless as an anti-scorbutic. If mariners had good limejuice on board ship, and if it were taken regularly, eighty per cent. of the cases of scurvy which occurred would never take place. A juror said that he considered the case one of manslaughter. The coroner said that the firm which supplied the ship were liable to a penalty of £20 under the Merchant Shipping Act—a fine far too small a punishment for such an offence. It should, however, be borne in mind that the provisions put on board by the same firm were of excellent quality. It was a case which he hoped the Board of Trade would take up, but the offence did not amount to one of manslaughter. The jury returned a verdict—"That the deceased died from scurvy; and the jury further say that the juice shipped on board the *St. Andrew's Castle* was a chemical decoction perfectly useless as a preventive of scurvy." The coroner said the case of this ship would be brought under the notice of the House of Commons.

THE SICK POOR IN ST. PANCRAS.

In a report presented lately to the St. Pancras guardians, it was stated that during the past three months the cost of the cod liver oil disposed of by the district medical officers to out-door sick-poor was £3 2s., and of quinine dispensed by them £3 12s. 10d. The total cost was £6 14s. 10d., being an average expenditure of about 2s. per week by each district medical officer. The value of medical extras supplied during the period was £89 13s. 4d., showing a decrease of £4 7s. 4d., compared with the preceding quarter. The result was considered in the report as "highly satisfactory." There was, however, an increase of £2 7s. 4d., as to cod-liver oil and quinine. It was also stated in the report that the supplying of nourishments by the relieving officers, instead of by the medical officers, had been attended with good results, and the system is found to answer well. In proof of this it was stated that "during the thirteen weeks ended the 23rd of February last the number of medical orders issued was 4097, which was a decrease of 534 as compared with the thirteen weeks ended the 1st of December, 1865." Having regard, therefore, to the superior administrative powers of the relieving officers, the report concludes by recommending "that in cases of great emergency only that may occur during the hours the relief offices are closed, the medical officers be authorized to give an order for meat in the first instance only, and that such cases shall be afterwards referred to the relieving officer to be dealt with in the usual manner. Also that the district medical officers shall furnish to the Stores Committee every Monday a return of the meat so ordered, setting forth the name, residence, and nature of the illness of each patient, and the date and hour on which the meat was ordered." There is also a further check placed on the medical officers in order to avoid extravagance on their part. Cod liver oil and quinine are to be supplied to them at the workhouse infirmary only. The quantities to be supplied at any one time to each district medical officer are one Winchester quart of cod liver oil and 1oz. bottle of quinine, and they are required to be particularly careful to report weekly the quantities they supply to each patient. After a discussion the report was unanimously adopted by the Board.

PAID NURSES IN WORKHOUSE HOSPITALS.—The guardians of the Strand Union have decided upon appointing paid nurses in their workhouse infirmary.

THE CATTLE PLAGUE IN BELGIUM.

THE *Nord* states that the rinderpest rages with such intensity among the horned cattle in the district of Merxem, near Antwerp, that the Belgian Government has found it expedient to send there two veterinary surgeons from Brussels, who ordered that 36 diseased animals belonging to one herd should be immediately slaughtered. The population of Merxem assembled the same night, opened the trenches in which the diseased cattle were buried, and carried off the carcasses. A guard of soldiers was sent from Antwerp to prevent a repetition of the act. The cattle-market in that district is suppressed. The slaughtering of diseased cattle at Merxem continues. Of 136 head on one farm, 96 were slaughtered on Sunday last. The civil and military authorities of the place, supported by a strong body of gendarmes, and attended by two veterinary surgeons, remain constantly on the spot. The Belgian *Moniteur* publishes a Royal decree announcing that the compensation allowed to the owners of cattle slaughtered in consequence of the rinderpest will not be paid unless the diseased animal shall have been one month in the owner's possession. This measure is adopted in consequence of the authorities having been convinced that the re-appearance of the rinderpest at Antwerp is the result of neglect on the part of the farmers, who, counting on the indemnity allowed by the Government, pay no attention to the health of the animals they purchase.

BIRTHS, DEATHS, AND MARRIAGES IN SCOTLAND FOR FEBRUARY.

THE following is the monthly return (omitting the tables) of the births, deaths, and marriages registered in the eight principal towns of Scotland during February last, published by authority of the Registrar-General:—During the month of February 1866, there were registered in the eight principal towns of Scotland the births of 3023 children, of whom 1533 were males, and 1475 females. Of that number, 2709 were legitimate, and 319 illegitimate, being in the proportion of 10.5 per cent. of the births as illegitimate, or one illegitimate in every 9.5 births. The proportions of illegitimate births in the several towns were as follows:—In Greenock 6.7 per cent.; in Perth, 7.5; in Leith, 7.6; in Glasgow, 9.7; in Edinburgh, 11.3; in Paisley, 11.5; in Aberdeen, 13.6; and in Dundee, 13.7 per cent. 599 marriages were registered during February, being the largest number registered in the month of February during the last eleven years. The deaths of 2178 persons were registered in the eight towns during the month, of whom 1103 were males, and 1075 females. This number is very much below that for the same month in 1864 or 1865, and is also about 200 below the average of the month for the ten previous years. Of the 2178 deaths recorded during the month, 875, or 40 per cent., were of children under five years of age. In Paisley, 30 per cent. of the persons who died were under five years of age; in Edinburgh, 32 per cent.; in Perth, 34 per cent.; in Glasgow and in Dundee, 41 per cent.; in Aberdeen, 43 per cent.; in Greenock, 47 per cent.; and in Leith, 50 per cent. The zymotic (epidemic and contagious) class of diseases proved fatal to 518 persons, thus constituting 23 per cent. of the mortality. The combined prevalence of measles, scarlatina, and typhus in Aberdeen, and of typhus in Paisley, caused this rate to be exceeded in each of these towns. Typhus was the most fatal epidemic, having caused 193 deaths, or 8.8 per cent. of the mortality. In Paisley it caused 19.4 per cent. of the deaths; in Dundee, 11.4; in Glasgow, 8.6; in Aberdeen, 7.8; in Edinburgh, 7.5; in Perth, 7.3; in Leith, 6.1; and in Greenock, 2.8 per cent. of the deaths. Of the 193 deaths tabulated under typhus, 144 were registered as typhus, 19 as enteric or typhoid fever, 5 as relapsing, 3 as continued, and 22 as gastric fever. Hooping-cough was the next most fatal epidemic, having caused 93 deaths, or 4.2 per cent. of the mortality. Scarlatina caused 64 deaths, measles, 54; diarrhoea and dysentery, 37; croup, 23; diphtheria, 14; metria, 6; and erysipelas, 12. Apoplexy caused 32 deaths; paralysis, 39; and diseases of the heart, 93. The deaths from inflammatory affections of the respiratory organs (not including consumption, hooping-cough, or croup) amounted to 427; those from consumption alone numbered 261. 59 deaths were attributed to violent causes, of which three were suicides. Three deaths were caused by intemperance, and one by delirium tremens. One male and six females were aged 90 years and upwards, the oldest being the widow of a serjeant, aged 100 years.

THE CATTLE PLAGUE.

THE *Mark-lane Express* states that the cattle plague recovery rate in the last week of February was, for the whole of Great Britain, 13.377 per cent. At the commencement of November it was only 5.235 per cent.

A report published in the same journal says that at the Horncastle Petty Sessions some days since Mr. Stanhope, M.P., was fined £20 and costs for having, on the 29th of January, removed two cows and sixteen bullocks from Revesby to Tattershall along a public highway.

J. J. Mechi, writing in the *Gardener's Chronicle* on this subject, says:—

"It is well known in Essex that nearly every case of an infected herd arose in the first instance from the purchase of an apparently healthy suckling calf. I know of many such instances in my own neighbourhood, although, fortunately, I have at present escaped, having declined to purchase my usual supply of calves. I believe the fact to be that if, immediately preceding parturition, the cow receives the germ of the rinderpest, the calf is also infected, and although for three to ten days after its birth it may appear vigorous and healthy, it then succumbs, and infects the stock with which it is mixed. Having had the experience of some 30 calves annually, either reared or bred here, I have observed the same result with ordinary fever, or other complaints of the cow."

A writer in the *Farmer*, who advocates the use of iodine as a disinfectant, gives the following extract from a letter which he received from a medical gentleman on the subject, instancing the results which it has accomplished, and pointing out the mode of using it:—

"I have now the happiness to tell you that iodine has been for three months under trial in this afflicted county of Cumberland, with the following result:—That in no farm where it has been fairly used has the cattle plague appeared; and that there are several farms which are surrounded by most virulent disease. These farms, where iodine was used to fumigate their byres, have for two months enjoyed complete immunity from disease. The mode of using the iodine is this:—To a byre of twelve cows take a common brick, place it upon the fire until it is quite hot, nearly red. Carry it into the byre, the cows all being in their stalls, close the doors and windows, then throw on the heated brick one-fourth of a wineglassful of iodine. Keep the doors and windows closed for ten minutes."

Mr. Panter, in giving evidence before the Commission, says, in reference to the London cowhouses:—

"The state of the London dairies themselves is not such as to encourage the propagation of disease. Forty or fifty per cent. of them are well managed and kept clean, and well ventilated and drained. There are exceptions which are grossly mismanaged. The usual mode of treating a cowshed in London with regard to replenishing the stock is that, as soon as a cow gets down to about five quarts of milk a day, the dairyman looks at her, and considers what she is worth the most for; and as they do not usually breed in London, she is sent to the butcher generally when the quantity of milk gets down to five quarts a day. The average time that a cow remains is not more than six months—hardly that. The moment she gets down to this low supply of milk she is sent into the market to be sold to the butchers, and very often the pleuropneumonias take them off long before that. The London dairies are never free from the pleuropneumonia for many weeks together. I think this is the result of the unnatural feeding. It comes from the artificial and heavy feeding upon brewers' grains in a great measure, that system being resorted to for forcing the milk to the greatest extent; and from the constant purchasing of animals in the market which introduces infection."

In reply to a question as to whether he thought it desirable for the health of cattle to do away with the London dairies, Mr. Panter said:—

"Certainly the London atmosphere cannot be a very wholesome one for the cattle to breathe; in a great many

parts of London at any rate. The trade could be carried on without having the dairies in London itself. The deficiency of milk is wonderfully met now by what comes from the country. Milk is brought by train, and London seems to suffer very little as regards the quantity of milk since the cattle plague has been in existence. I consider that the milk we have at Hendon is better than the milk that is produced actually in the cowsheds in London."

UNFOUNDED CHARGE AGAINST A PARISH SURGEON.

THE Brighton papers contain an account of a charge of neglect preferred by one Henry Davis of Essex Cottage, College-place, against Mr. George Geere, Medical Officer for the eastern district of the parish of Brighton. The proceedings were ordered by the Poor-law Board, and were conducted by the Poor-law Inspector of the district. The subject of the inquiry was the death of a woman named Fanny Hutson, who died on Tuesday, Nov. 21 last, at 11, Paradise-street, the property of Mr. Davis, who alleged that she had died in her confinement through the negligence of Mr. Geere. He called witnesses with the view of showing that Mr. Geere had not promptly attended to the case; but their evidence was of a hearsay character only, founded upon statements which were said to have been made by the husband of the deceased, who had died about a fortnight after the wife of typhus fever. Mr. Pocock, one of the District Surgeons of the Dispensary, who attended the deceased woman up to the period of her confinement, informed the Court that she was suffering from typhus fever, and there seemed to be no doubt that the fever produced a premature birth and death. The persons who were with the family before and after the woman died said they heard no complaint made by the husband against Mr. Geere. All that could be construed into negligence was the unsupported statement that he had been sent for three times on the day of her death, and that he did not attend till after she was dead. It appeared that deceased had been attended from Nov. 17th to 20th by Mr. Pocock for fever, but when he was told she was pregnant he (it being against the rules of the Dispensary to attend to cases of parturition) advised her removal to the Workhouse Infirmary, or the obtainment of a parish Surgeon. On Tuesday, Nov. 21st, the husband made application to the parish, and obtained a medical order from the assistant-overseer for Mr. Geere to attend to the case. This order was issued at a quarter past twelve o'clock, and, when left at Mr. Geere's surgery, he was not at home. The woman was confined very shortly after the husband got back, assisted by a midwife who had been sent for; and at two o'clock a little girl was sent with a note to Mr. Geere to tell him Mrs. Hutson was put to bed. He was still out, and the girl brought the note back about four o'clock, having gone to a cousin's in the meantime, and at six o'clock Hutson was going again to Mr. Geere, when he met him on the road. By the time he arrived the woman was dead. The assistant-overseer explained that, when the order was issued, the man made no reference to the case being urgent; that he never even said his wife was pregnant, or the order would have been endorsed "urgent;" but he merely applied for his wife to be removed to the Infirmary as suffering from fever. Mr. Geere, in reply to the Inspector, said, had the order been marked "urgent," his deputy would have attended to the case. It was proved that others of the family had suffered from fever, and the description of the house was horrible. There were only three rooms in it—a bedroom, kitchen, and washhouse; no back yard or back windows, and there was a stench so offensive that M. Pocock said he was compelled on one occasion to stand outside the house to talk to the husband. Mr. Barber, one of the parochial visitors, said he asked the eldest daughter from whence this stench arose, and she pointed to a copper in the corner of the washhouse, and said, "That is where the 'matter' runs from the copper across the kitchen." There was a mark where something

had been running from the copper, and had dried up; but in the area, close to the door, there was a privy, which was full and very offensive, and the bricks and mortar had fallen down. The daughter told him they could not use the privy, but were obliged to make use of utensils in the house, and she believed that what oozed from the copper came from the back yard of No. 10, next door. In this "house" there lived eight people! Its condition was reported to the Sanitary Committee of the Town Council, and Mr. Davis, who accused Mr. Geere of reporting it, admitted that he made no complaint against Mr. Geere till after the house was reported, and he gave as a reason why the complaint was so long deferred—six weeks after the death—that he could not obtain reliable information. At the conclusion of the inquiry the inspector said he had to make a report to the Poor-law Board, and had no doubt the guardians would receive it shortly with (which he had no doubt they would like) an expression of opinion upon the case.

REPRESENTATION OF THE UNIVERSITY OF LONDON.

At an extraordinary meeting of the members of Convocation of this University, held on Wednesday, Dr. Storrar in the chair, Mr. Jessel, Q.C., moved the following resolution:—"That a petition be presented to both Houses of Parliament praying that two members may be given to the University of London, such petition to be signed by the Chairman of the Convocation." He remarked that the number of constituents, supposing the University of London to be represented, would be 1729. In 1869, at which time any new Reform Bill might be supposed to come into operation, the constituency of the University of London would be 2000. It was clear, he thought, that there could not be a better constituency than a number of learned and accomplished men, for it was impossible that such a body of men would consent to be represented by a man who was inferior to the bulk of them in knowledge and education. Such a constituency, moreover, would be above all bribery and corruption, and beyond all suspicion of it. On these grounds he held that University representation would be a benefit not only to the University, but to the whole country. He should like to know what constituency could be named which would give 2000 persons equal in intelligence, experience, and knowledge, to say nothing of social standing, to those of the University of London. The members of the University who were entitled to vote were under fifty years of age and above twenty-four, so that all the voters would be in the prime of life. A representation of the University of London would also accomplish this, that every class of learned men would be represented, more especially the class of medical men, of whose accomplishments the University of London might justly be proud. The claims of the University had been recognized by three Governments, the Liberals, the Tories, and the Government of Lord Aberdeen, which might be supposed to represent the middle party between them. Under these circumstances he thought they had a claim to be put on an equality with the old Universities of Oxford and Cambridge. He hoped that the time would come when, the University sending two members to Parliament, the word "religion" would never be mentioned either by the electors or the elected.

The motion was seconded by Mr. R. N. Fowler (late a candidate for the representation of the City of London), who strongly urged the claims of the medical profession to have a voice in the House of Commons. Several gentlemen addressed the meeting in support of matters of detail, especially a recommendation of the educational franchise, and eventually the resolution was unanimously agreed to. It was then arranged that Dr. Storrar, the Master of Convocation, should take measures to secure the presentation of a petition to the House of Commons founded upon the resolution.

Medical Obituary Notices.

JOHN SPURGIN, M.D., F.R.C.P.

WE regret to announce the death of this well-known and estimable physician, and the sorrow with which the intelligence of his death has been received is increased by the circumstance that he himself attributed the fatal illness from which he has for some months been suffering to the injuries he received from robbers in Bishopsgate-street in September last. On one of the days in that month, between nine and ten in the evening, he had returned from visiting a patient at Wanstead, and had got only a few hundred yards from the Great Eastern Railway, on foot, when he was suddenly (to use his own expression) "buted" by a man, who threw himself head-foremost at Dr. Spurgin, striking him on the chin and breast, and falling on him as Dr. Spurgin fell. The ruffian, placing his knee on the pit of the stomach, snatched at a gold chain and valuable gold watch, and waving them hurriedly to some one behind, rose and commenced running in an opposite direction. After lying stunned for a moment, Dr. Spurgin rose and attempted to follow the garrotter, whom he still had in sight, when a man suddenly appeared at the corner of an alley, and exclaimed, "Halloo! What's the matter?" "Why," gasped Dr. Spurgin, "that man has just stolen my watch!" "Oh, has he?" was the reply, and in an instant the unfortunate gentleman was tripped up and fell prostrate on the flags, sustaining a second time serious injuries. Both miscreants got off scotfree; there was no policeman near or in sight, and no one to lend a helping hand till it was too late.

Dr. Spurgin obtained his degree at Cambridge in 1825, and became a Fellow of the Royal College of Physicians of London, in 1826, the custom at the College at that period being to admit almost immediately into the Fellowship all medical graduates of Oxford and Cambridge. For many years Dr. Spurgin held the honorary appointment of Physician to the Foundling Hospital, an office which he relinquished a few years since. He delivered the Harveian Oration in 1851, and in 1853 he delivered six lectures on *Materia Medica*, which he subsequently printed in a small volume; and among other works he wrote one entitled, "The Physician for all; his Philosophy, Experience, and Mission." Dr. Spurgin was a man of considerable general and scientific attainments, and was for many years a director of the Polytechnic Institution. He possessed a very good, though rather limited, practice. His religious tenets (those introduced by Swedenborg) having introduced him to many of the followers of that sect. He had passed through many vicissitudes of life, having at one time lost considerable sums of money by unfortunate ventures, but latterly he had again risen to affluence. He had also experienced some severe domestic afflictions. He was twice married, and was 68 years of age at the time of his death. He was held in great and deserved esteem by a large circle of friends.

J. WALLER NELSON, B.A., M.R.C.S.ENG.

WE are sorry to have to record the death of Mr. J. Waller Nelson, B.A., M.R.C.S.Eng., eldest son of Dr. Nelson of Birmingham. Mr. Nelson's death resulted from diphtheria, caught in the General Hospital, where he has for some time past been residing as one of the resident pupils, and lately as resident medical officer (*pro tem*). Some few months ago a former resident pupil of the hospital also fell a victim to the same malady. Mr. Nelson was a very distinguished student of Queen's College, Birmingham, and a graduate with high honours of the London University. His untimely death, at the early age of 23 years, and at the beginning of a career which promised to be more than ordinarily brilliant, has caused much regret among the profession in Birmingham.

THE PRIORITY OF INVENTION IN LOCAL ANÆSTHESIA.

THE application of ether as a local anæsthetic by RICHARDSON'S apparatus has met with much success, excited much interest, and secured for the inventor a celebrity which must be most gratifying to him. We should be sorry to detract from the credit which is certainly due to Dr. RICHARDSON for the practical application of an agent, the use of which had certainly not before been generally known or appreciated. Nevertheless, we must claim fair play for those to whose observation and judgment the principle of the application is due, and we are certain Dr. RICHARDSON will be as ready to do them justice as we are. The credit of the first suggestion as to the local application of anæsthetic vapour undoubtedly is due to Dr. HARDY of Dublin, who published in THE MEDICAL PRESS of November 15, 1854, an account of the instrument now known as HARDY'S Vapour Douche, by the use of which he hoped to obtain a condition of local anæsthetic without the inhalation of ether or chloroform. That instrument is still well-known in Dublin, and Dr. HARDY'S observations on it were republished by him and are in the hands of many of our readers. We don't set up Dr. HARDY'S claim to priority in Dr. RICHARDSON'S principle, because the refrigeration of the part by evaporation was not one of the objects of the Vapour Douche, but we notice it to show that the specific anæsthetic effect of vapourised ether was utilised years before Dr. RICHARDSON proposed it. Dr. RICHARDSON, of course, lays no claim to originality in the use of cold for allaying pain, and it is not therefore necessary to go into the details of ARNOTT'S or BLUNDELL'S inventions. What Dr. RICHARDSON asks credit for having done is, that he at once combined the principles of HARDY'S douche, ARNOTT'S congelation, and the well-known toy perfume vapouriser (the latter being only a simplification of the French fluid pulveriser), in the instrument which bears his name. The production of cold for anæsthetic purposes by the evaporation of ether, was on record long before Dr. RICHARDSON suggested his apparatus, and every effect which it is capable of producing was publicly anticipated long before the vapouriser existed at all. The following extract from a work entitled "A Treatise on Surgical Anæsthesia," by MAURICE PERRIN and LUDGER LALLEMAND, published in Paris in the year 1863, proves this fact:—

"Monsieur Guérard, instead of trying the inhalation of air charged with the vapour, or of making use of douches, formed the idea of bringing the ether to bear directly on the parts he wished to render insensible. By his instructions, M. Mathieu made him an apparatus calculated to realize the desired effect. The instrument is a small moveable syringe, which, when once filled with ether, is placed upon an elongated support, fitted with a spring. This spring, as it stretches, moves the piston of the syringe as soon as the cock, with which the latter is fitted, is opened. The whole apparatus is mounted on two split stems, on which the mouth-piece of an ordinary pair of bellows is placed, and which have to be blown whilst the jet of ether is being thrown on the skin. This modification of M. Guérard commenced a new phase of the question of local anæsthesia. The author announced to the hospital surgeon that he had in several cases obtained excellent effects from his method. Others have been equally satisfied with it, but nobody has studied the question with so much care as M. Richey, who made it the subject of a very interesting paper. The cases detailed by M. Richey are

fourteen in number and classed under three heads. The first comprises only one case, in which the evaporation of the ether was followed by no positive result; the second head embraces three cases in which the anæsthesia was complete enough to make the skin insensible, but not of sufficient duration to allow the operation to be completed without pain; lastly, under a third head are ten observations relative to the opening of a ganglionic abscess in the groin, two phlegmons in the arm-pit, an abscess on the breast, a phlegmon on the arm, to the cutting of an aneurism on the thigh, a suppurated hygroma, and lastly, two whitlows. In every one of these cases the anæsthesia was complete and sufficiently prolonged. The author has noticed that under the influence of ether rapidly evaporating the skin does not change colour to any great extent, and that the capillary circulation is in no way changed. Some patients complain of a disagreeable prickly sensation; others, and these the greater proportion, feel nothing but an agreeable freshness. Above all, localized etherization has never been followed by the slightest inflammatory symptom. The appliance used by M. Richey was sometimes that of M. Guérard, oftener a simple ordinary bellows. The ether was allowed to fall drop by drop on the part to be benumbed. An assistant, furnished with a pair of bellows, kept up the current of air."

But there has been a still closer approximation to Dr. RICHARDSON'S apparatus, and any of our readers who can refer to the source of our information will find that as far back as twelve years ago an apparatus was invented which effected exactly the same purpose as Dr. RICHARDSON'S instrument by almost identical means.

In the *Gazette des Hôpitaux* for April 1, 1854, there is a description and figure of M. MATHIEU'S instrument for producing local anæsthesia by congelation, which clearly and distinctly prove that it differs in nothing except in mere mechanical detail from that of Dr. RICHARDSON. Not only was the local anæsthesia produced by congelation, and the congelation by the evaporation of sulphuric ether, but to hasten that evaporation the ether was impinged upon the part to be frozen in the form of spray produced by a rapid current of air. To attain this object a reservoir of ether compressed by a spring piston was attached to a pair of bellows, in such a manner that a tube with a minute opening poured a small stream of ether right in front of the nozzle of the bellows, the current of air from which instantly converted it into fine spray, and in that form blew it upon the part to be frozen. In mechanical detail Dr. RICHARDSON'S instrument is twelve years in advance of MATHIEU'S, but in the principle upon which it is based it can hardly claim to be superior. We do not for a moment suggest that Dr. RICHARDSON knowingly appropriated the principle of MATHIEU'S instrument. He enjoys the credit of having planned the development of the fluid-pulveriser into a useful and practically convenient apparatus, the ready adoption of which is *prima facie* evidence of its superior efficiency.

POOR-LAW MEDICAL REFORM.

MR. GRIFFIN begs us to inform the Poor-law Medical Officers that the following subscriptions have been received by him towards the funds of the Association:—

G. Taylor, St. Faith's, 10s.; H. D. Ellis, Poole, 5s.; Haynes (New and Haynes), 21s.; F. Owen, Epsom, 10s.; A. Stedman, Epsom, 10s.; H. G. Hardy, Auckland, 5s.; Newman and Atkins, Cosford, 10s.; A. Roberts, Holborn, 10s. By Mr. Prowse—T. Odell, Hertford, 10s.; H. Jepson, Kingston, 10s.; A. Kirkland, Amersham, 10s.

BOOK RECEIVED.

On a New Method of Applying Remedial Agents to the Cavity of the Tympanum. By Ed. Bishop, M.D., M.R.C.S.E. London: Churchill.

Medical News.

UNIVERSITY OF LONDON.—The following candidates passed the late examination for the degree of Master in Surgery:—

Andrew, Edwin, M.D., University College.
Deas, Peter Maury, M.B., University of Edinburgh.
Examination for Honours.
Deas, Peter Maury, M.B. (Scholarship and Gold Medal), University of Edinburgh.
Andrew, Edwin, M.D. (Gold Medal), University College.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 15th inst.:

Ellis, William Henry, Swarcesy, Camb.
Ley, Richard, South Molton.
O'Neill, Patrick James, Canning Town, Essex.
Prince, Frederick Tickell, Sawston, Camb.
Pritchard, John Frederick, Southsea.
Smith, Henry Cecil, Kensington-park-gardens.

The following gentlemen also on the same day passed their first examination:—

Ash, Robert Vacy, St. Mary's Hospital.
Stainthorpe, Thomas Edward, Middlesex Hospital.

DR. GRAYL HEWITT has been elected Honorary Fellow of the Obstetrical Society of Berlin.

THE PERILS OF PEDESTRIANS.—From returns recently made to the House of Lords it appears that during the 14 months between January 1, 1865, and the end of February last, there were reported by the Metropolitan Police no less than 163 cases in which persons were run over and killed in the streets of London. There were, moreover, 1938 persons maimed or injured from similar causes. The city police report within the same period 17 fatal cases and 237 instances of bodily injury. As might be expected, the far larger proportion of disasters have occurred from vehicles in which the horses were driven, although even led horses have caused the deaths of 23 persons and the injury of 80 others.

ALLEGED POISONING BY MILK FROM A COW RECOVERING FROM RINDERPEST.—The *Pall-mall Gazette* states that the wife of Mr. Thomas Woolfe, of Standon Hall, in Staffordshire, was seized with the symptoms of irritant poison after tasting milk obtained from an animal recovering from cattle plague.

THE CHEMICAL SOCIETY.—At a meeting of the Chemical Society on Thursday week Dr. Frankland gave the results of his analyses of the drinking waters of London during the several months of the year; the said investigation having been made at the request of the Registrar-General. Dr. Frankland discovered that the amount of solid impurities in London river water is always greatest in wet weather; also that the organic matter it contains is greatly increased during rain. The water was purest during the long drought of last summer, and most contaminated during the rainfall in the latter part of October. This increase in organic matter he attributes chiefly to the flushing of the sewers of those towns which drain into the Thames above Teddington Lock, and in the case of the New River and the Lea to the flow of rain water over highly-manured fields.

ETHNOLOGICAL SOCIETY.—On the 13th inst. an elaborate paper was read "On the true assignation of the bronze weapons, &c., found in Northern and Central Europe," by Sir J. Lubbock and Mr. F. Lubbock. The authors maintained that implements and weapons of bronze were rarely, if ever, associated with remains of Roman origin. Considering the abundance of bronze weapons on the one hand, and of Roman remains on the other, it was to be expected that in some cases they would be found together. In order to show, however, the nature of the objects generally associated with bronze, a list was given of the contents of a large number of tombs opened by Sir R. Colt Hoare and Mr. Bateman, which contained bronze weapons, &c., and not one of which contained a single object which could be ascribed to the Roman period. The authors gave many reasons why these bronze weapons should not be considered as of Roman origin, and at the conclusion of the paper recapitulated the grounds for referring them to a period anterior to the conquest of Britain by the Romans.

DWELLINGS FOR THE POOR.—A conference of Poor-law guardians was lately held at St. James's Hall in reference

to the Houseless Poor Act; Dr. Brewer presided. A resolution was carried, declaring it to be desirable that the present Houseless Poor Act should be repealed and a more suitable measure passed.

THE SEWING MACHINE.—The principle of passing and arresting the thread in Singer's sewing machine was taken from an instrument invented by Mr. W. Rawlings Beaumont, of Toronto, an honorary fellow of the Royal College of Surgeons of England, who used the ingenious instrument for passing sutures in vesico- and recto-vaginal fistula. Singer took his idea from Mr. Beaumont's instrument exhibited in the shop of Freeman, a surgical instrument maker in New York.

UNIVERSITY COLLEGE HOSPITAL.—The annual festival of this valuable charity will take place at Willis's Rooms on Wednesday, the 18th of April. The Duke of Cambridge has consented to preside on the occasion; he will, we trust, be well supported. The amount of relief afforded by the hospital may be stated as follows:—Upwards of 1896 in-patients are admitted, nursed, and cured in the course of the year; 10,415 receive medical and surgical treatment, as out-patients; nearly 12,000 are attended to as casualties; relief is administered to upwards of 1440 ophthalmic cases; and 800 women in childbirth are attended at their own habitations. The annual cost of maintaining the hospital in its present state is £6500, whilst its certain income from all sources—annual subscriptions, fees paid by students for clinical instruction and relinquished by the physicians and surgeons for the benefit of the charity, and interest from investments—does not amount to more than £2840; so that every year, appeals to friends and the public to supply a deficiency of ordinary funds amounting to nearly £4000 are indispensable.

AIR IN LONDON LAW COURTS.—Dr. Augustus Smith reports that some specimens of air from the Court of Queen's Bench, examined by him, are the most deficient in oxygen of any specimens found by him during the day above ground. They were almost exactly the same as many specimens of air found in metalliferous mines.

HONORARY PHYSICIAN TO THE QUEEN.—The *London Gazette* contains the following announcement under the head of Army Medical Department:—Inspector-General of Hospitals George Steward Beatson, M.D., to be Hon. Physician to Her Majesty, vice Sir John McGregor, K.C.B., M.D., deceased.

WEBBER V. WILLICOMBE AND OTHERS.—Mr. Webber, of Tunbridge Wells, has obtained a verdict of £50 damages against two of the ringleaders of the mob who, it will be recollected, broke his windows and burnt him in effigy. It was stated at the trial that the plaintiff had excited ill will by stating his opinion on the state of the sewerage of the town.

THE OZONE THEORY.—Professor Frankland states that the alleged presence of ozone in the atmosphere cannot be proved. Thus, there is no evidence that atmospheric ozone has any effect on the prevalence or absence of infectious diseases, as commonly supposed.

THE PROGRESS OF HIPOPHAGY.—Great success has attended the introduction of horse-flesh in Berlin as an article of human food. In 1865, 2241 horses were slaughtered for this purpose. The meat is perfectly wholesome, and tolerably palatable, resembling rather coarse beef.

DUNDEE INFIRMARY.—A quarterly meeting of the governors of the Dundee Infirmary was held last week—Provost Parker in the chair. A report by the medical officers was read, to the effect that the accommodation provided in the present Infirmary is not sufficient for the wants of the town, and that the best remedy for the deficiency would be the erection of a separate fever hospital. Were this erected, the additional accommodation set at liberty in the present building would permit the taking of children as patients. A committee of the directors expressed their approval of the conclusion come to by the medical officers; but said they could not, under the present circumstances, recommend the governors to incur the expense which the extension would entail upon them. The income of the present year was estimated at £3950, and the expenditure at £5000. It was ultimately agreed to print the statements submitted, and to call a meeting in about a month to consider what steps should be taken.

Notices to Correspondents.

Query.—Is it unprofessional to consult with a man who, although not registered, has a diploma which you have seen, entitling him to registration (and which on application to its source you find is genuine), he not wishing to register if till he has passed another one, for which he has passed the first half of an examination?—H. R. H.

Quicquid.—Supposing the facts to be correctly stated, it does not appear to us that a committed any breach of professional etiquette, and therefore it has no just ground of complaint.

A Beginner.—The new chemical formulæ are founded upon some theoretical investigations upon the atomic weights of bodies, and they are adopted in many recent works.

Justicia.—Ball is the fruit of the Ægle Marmelos, a plant of the natural order of Aurantiaceæ.

Mrs. J. P.—The newspaper has been received.

M. F. Z.—The next meeting of the Medical Council will take place in Whitsun week.

R. T.—The subject is not one which we think can be suitably discussed in our columns.

Dr. M.—It is usual, under such circumstances, to divide the fee.

Habitans in Stoco.—We shall be glad to receive the communication referred to.

Mr. S., Liverpool.—The person named has no legal qualification, as far as we are aware.

A Pharmacist.—The publication of the new Pharmacopœia has been delayed owing to the serious illness of one of the Editors.

GRIFFIN TESTIMONIAL FUND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The following subscriptions have been further received on behalf of the above fund:—C. H. Carter, Esq. Dewsey, 10s. 6d.; J. Breach, Esq., Aston-upon-Thorpe, 10s.; Dr. Edward Ray, Dulwich, £1 1s.; amount previously announced, £134 5s. 3d.; received at Lancet office, £13 11s. 6d.

ROBERT FOWLER, M.D.,

Treasurer and Hon. Sec.

145, Bishopsgate-street-out., March 21, 1866.

BIRTHS and DEATHS Registered and METEOROLOGY during the Week ending Saturday, March 17, 1866, in the following large Towns:—

Table with columns: Boroughs, etc., Estimated Population in middle of the Year 1866, Persons to an Acre, Births registered during the week ending March 17, 1866, Deaths, Temperature of Air (Fair), Rain Fall, In Inches, In Tons per Acre.

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29.396 in. The barometric pressure was 30.23 in. on Sunday, and fell to 28.97 in. on Saturday.

The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the 10 years 1851-60 to the present time.

Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in workhouses situated outside the municipal boundaries.

The mean temperature at Greenwich during same week was 36.8deg

APPOINTMENTS.

COLLIE, A., M.D., has been appointed Assistant Medical Officer to the London Fever Hospital.

DAVIDSON, ALEXANDER, M.A., M.B. Edin., has been appointed Lecturer on Comparative Anatomy and Zoology at the Liverpool Royal Infirmary School of Medicine.

DEWSON, Mr. F. S., has been appointed Resident Dispenser at the Queen's Hospital, Birmingham.

GIBSON, FRANCIS W., has been appointed Assistant Medical Officer to the Broadmoor Criminal Lunatic Asylum, near Wokingham.

JACKSON, JABER, L.F.P.S.G., L.M., has been appointed Medical Officer and Public Vaccinator to the Fourth District of the parish of Birmingham.

MAYNICE, OLIVER C., M.R.C.S. Eng., has been appointed Assistant Surgeon to the Royal Berkshire Hospital, Reading.

MEADOWS, ALFRED, M.D. Lond., has been appointed an additional Physician to the Hospital for Women, Soho-square.

MILBURN, FREDERICK L., M.R.C.S. Eng., has been elected Assistant House-Surgeon to the General Hospital, Nottingham.

NESHAM, THOMAS C., M.D. Edin., has been elected Surgeon to the Newcastle-upon-Tyne Lying-in Hospital.

NICOLL, R. CHARLES, Esq., F.R.C.S., has been appointed Medical Officer to the Charterhouse.

SMITH, WILLIAM A., M.D. St. And., has been appointed an additional Physician to the North London Consumption Hospital.

STURGES, OCTAVIUS, M.D., has been appointed an additional Physician to the North London Consumption Hospital.

WHITE, WILLIAM L., M.B., has been appointed Assistant Medical Superintendent to the Dundee Royal Infirmary.

WILLIAMS, W. RHYNS, M.D., has been appointed Resident Physician and Medical Superintendent of the Royal Hospital, Bethlehem.

YATES, Mr. G. L., has been appointed Assistant Dispenser to the Burlington-street Dispensary, Liverpool.

YORKE, CHRISTOPHER F., L.R.C.S.I., has been appointed Surgeon to the Constabulary, Granard, County Longford.

Births, Deaths, and Marriages.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

BARRIE.—On March 10, at Glasgow, the wife of John Barrie, M.D., of a daughter.

BESWELL.—On March 20, at 5, Loughborough Villas, Brixton, the wife of Richard Buswell, M.R.C.S.E., of a son.

CRISP.—On March 16, at 42, Beaufort-street, Chelsea, the wife of Edward Crisp, M.D., of a daughter.

DATE.—On March 8, at Ilkeston, Derbyshire, the wife of William Date, M.R.C.S. Eng., of a son.

DRYSDALE.—On March 19, at Sheerness, the wife of A. Knox Drysdale, F.R.C.S.; Surgeon R.A., of a son.

FARQUHARSON.—On March 7, at St. John's-road, Stockton-on-Tees, the wife of John Farquharson, L.R.C.P. Edin., of a son.

LEGAT.—On March 8, at South Shields, the wife of Andrew Legat, M.D., of a son.

MAWHINNY.—On March 5, at Woodlawn, Mount Nugent, Co. Cavan, the wife of Dr. P. Mawhinny, of a son.

McCABE.—On March 2, at Waterford, the wife of Dr. McCabe, of a daughter.

MOXON.—On March 8, at Northampton, the wife of William Moxon, M.R.C.S.E., of a daughter.

MURO.—On March 15, at Boulogne-sur-Mer, the wife of Alexander Muro, M.D., of a daughter.

FLEMING—CHARLES.—On March 1, at Moneymore, Stunuel Fleming, L.R.C.S. Edin., to Margaret, daughter of the late Stewart Charles, Esq.

FULTON—HANNA.—March 9th, in the Railway-street Presbyterian Church, Lisburn, by the Rev. R. S. Erwin, Thomas Fulton, Esq., M.D., L.R.C.S. Ed., to Matilda, eldest daughter of John Hanna, Esq., both of Ballynahinch.

LYALL—ROSE.—On February 22, at Haverfordwest; David Lyall, M.D., Staff-surgeon R.N., to Fanny Anne, only daughter of George Rowe, Esq.

MASSY—YIELDING.—On March 14, at St. Thomas's Church, Dublin, D. G. Massy, Esq., Bengal Medical Staff, to Fanny Augusta, eldest daughter of H. Massy Yielding, Esq.

PRICE—HAVERSON.—On March 1, at Upper Norwood, William P. Price, M.D., to Annie Eliza, eldest daughter of J. P. Haverson, Esq.

BOWDEN, ALFRED, M.R.C.S. Eng., off Port Phillip Heads, on January 15, aged 45.

GRAY, WILLIAM, M.R.C.S. Eng., late of Orford-hill, Norwich, on March 4, aged 35.

JONES, W., M.R.C.S. Eng., at Byrom-street, Manchester, on March 3, aged 51.

LOWE, JOHN, Surgeon, at Coupar Angus, N.B., on March 9, aged 84.

MELSON.—On the 21st inst., after a few days' illness, aged 23 years, John Walter Melson, B.A. (Lond.), M.R.C.S., and L.S.A., eldest son of Dr. Melson, of Birmingham.

MORISON, Sir ALEXANDER, M.D., Balerno Hill House, Edinburgh, on March 14, aged 87.

PARCHAPPE.—M. Parchappe, Inspector-General of Asylums, one of the most distinguished of the French psychologists, well known by his writings on the nervous system and as Director of the St. Yvon Asylum, Rouen, which was built after his design, died March 12, aged 65.

ERRATA.

At page 279, in Mr. Symes' account of a case of Separation of the Symphysis Pubis, ninth line from top, read *tra* for "two."

In Dr. Paterson's letter on "Cattle Plague," page 235, line 9, for "purulent" read *yellow*: line 13, for "on" read *in*; line 22, for "had" read *has*; for "purulent" read *yellow*, for "ensues" read *ensue*.

LIEBIG'S FOOD FOR

Prepared strictly from the Formula of
Baron Liebig, by

HOOPER,

OPERATIVE CHEMIST,

Wholesale of Barclay, Edwards, Newbery, all Patent Medicine

INFANTS & INVALIDS.

Sold in Tins, 1 lb., 1s.; 3 lb., 2s. 6d.; 6 lb., 5s.,
by all Chemists and Druggists,
and direct from Mr. HOOPER'S Establishments.

7, PALL MALL EAST,
And 55, GROSVENOR STREET.

COUNTY AND CITY OF CORK MEDICAL PROTECTIVE ASSOCIATION.

Resolutions of Annual Meeting held at the Royal Cork Institution, on Tuesday, March 20, 1866.

I.
Moved by Dr. A. IL JACOB; seconded by Dr. N. J. HOBART:—
"That the Report now read be adopted, printed, and extensively
circulated."

II.
Moved by Dr. MACKESY; seconded by Dr. GOTTLING:—
"That, convinced as we are, by an increasing experience, of the
paramount importance of securing to the country competent practitioners
in Medicine and Surgery, we desire to record our anxious wish
to see the Medical Council so modified, both as to its constitution and
its powers, that we may look with confidence to its enforcing a high
and uniform standard of education, both preliminary and profes-
sional, on all the Licensing Bodies throughout the United Kingdom."

III.
Moved by Dr. POPHAM; seconded by Dr. O'FLYNN:—
"That it is the desire as well as the duty of this Association to for-
ward, as far as possible, the views of Government in obtaining, by
means of the various Registrations and otherwise, a complete body of
statisticians of the sanitary state of the country, as a means towards the
further preservation of the lives of the community. We would, there-
fore, urge on our professional brethren the peculiar importance of the
duty that devolves on them in these respects, reminding them that here,
as in all similar cases, every section of the commonwealth has its duties
as well as its privileges."

IV.
Moved by Dr. O'CONNOR; seconded by Dr. McEVERS:—
"That the present sanitary laws affecting Ireland are so scattered
through Corporation, Poor-law, and other enactments, as to be difficult
of access, and hence comparatively inoperative. We, therefore, venture
to suggest to Her Majesty's Government the expediency of revising the
whole subject, embodying what is at present valuable in a new act, and
placing its administration in the hands of one efficient executive body."

V.
Moved by Dr. BENNETT; seconded by Dr. O'NEILL:—
"That we consider that the present inadequate remuneration of
Medical Officers under the Poor-laws is an injustice to the poor and to
the ratepayers as well as to the profession; and that a more liberal
policy, such as would attract well-educated men to the service, and
secure genuine drugs for the restoration of the sick, would be a sound
and a large economy, inasmuch as numbers, who are now unattended
to or inefficiently treated, and who, in consequence, with their families,
become a permanent tax on the rates, would then leave more than the
amount now spent on their maintenance to its more legitimate applica-
tion in properly carrying out the objects of the law."

VI.
Moved by Dr. GODFREY; seconded by Dr. CREMEN:—
"That it is the deliberate opinion of this meeting that the Poor-law
Medical Officers of Ireland are entitled to a retiring allowance, when,
from old age and infirmity, after long and faithful service, they become
incapable of further labour; and that we again recognize the opinion
now so generally expressed, that one-half of the salaries of these officers
should be paid out of the Consolidated Fund."

VII.
Moved by Dr. MORROGH; seconded by Dr. CURTIS:—
"That the fact of the Royal Commission lately appointed to consider
the position of the Medical Officers of the Army and Navy having re-
ported favourably on behalf of the Officers of both Services, is very
gratifying to this meeting; and we trust that the report may be the
means of restoring that confidence in the good faith of the heads of
both departments, which is essential to the effective working of the
service, and to the well-being of the British soldier and sailor."

VIII.
Moved by Dr. CUMMINS; seconded by Dr. O'CALLAGHAN:—
"That medical witnesses, when subpoenaed by the Crown to give
evidence in courts of justice are most inadequately remunerated,
this remuneration being subject to the caprice of the powers that be;
and meeting therefore maintains that medical witnesses are, in all such
cases, fully entitled to a minimum fee of £2 2s. a day, with an allow-
ance for hotel and travelling expenses."

IX.
Moved by Dr. BEAHISH; seconded by Dr. SHINKWIN:—
"That we cannot separate without expressing our deep and heartfelt
regret at the heavy loss this Association has sustained by the death of
our valued Vice-President, Dr. Corbett. His exertions to improve the
condition of his profession, begun before this Association was in exist-
ence, were here more effectively carried out; and whatever good the
Association may have achieved for the profession, which he loved and
honoured, was at all times materially aided by the untiring zeal, the
sound sense, and the mature judgment of our lamented colleague."

X.
Moved by Dr. O'FLYNN; seconded by Dr. O'KEEFE:—
"That no stronger evidence can be given of the just claims of the
Medical Profession for a redress of grievances than the fact that their
exertions in this behalf have uniformly received the kind and able sup-
port of the Press of Ireland, to whom we again offer our sincere and
grateful acknowledgments."

Crosse and Blackwell, Purveyors in

Ordinary to Her Majesty, respectfully invite atten-
tion to their PICKLES, Sauces, Tart Fruits, and other table delicacies,
the whole of which are prepared with the most scrupulous attention to
wholesomeness and purity. The practice of colouring pickles and tart
fruits by artificial means has been discontinued, and the whole of their
manufactures are so prepared that they are not allowed to come in con-
tact with any deleterious ingredient. A few of the articles most highly
recommended are, Pickles and Tart Fruits of every description, Royal
Table Sauce, Essence of Shrimps, Soho Sauce, Essence of Anchovies,
Jams, Jellies, Orange Marmalade, Anchovy and Broiler Pastes,
Strasbourg and other Potted Meats, and Galf's-foot Jellies of various
kinds for table use. C. and B. are also Sole Agents for M. Sayer's
Sauces, Relish, and Aromatic Mustard; and for Carstairs' Sir Robert
Peel's Sauce, and Payne's Royal Osborne Sauce. The above may be
obtained of most respectable Sauce Vendors throughout the United
Kingdom; and Wholesale of

CROSSE and BLACKWELL, 21, Soho-square, London.

Aerated Lithia Water.—Messrs. BLAKE,

SANDFORD, and BLAKE, are prepared to supply the
LITHIA WATERS (of which they were the original manufacturers
under Dr. Garrod's instruction) of any strength prescribed by the Pro-
fession for special cases. Those in constant use contain two grains and
five grains in each bottle, either by itself or combined with BICAR-
BONATE of POTASH or PHOSPHATE of AMMONIA.—Also, Potash,
Citrate of Potash, Soda, Seltzer, Vichy, and Mineral Acid Waters, as
usual.

BLAKE, SANDFORD, and BLAKE, Pharmaceutical Chemists
47, Piccadilly.

Chocolate (Menier's French) for Break- FAST.

(Manufactory at Noisiel-sur-Maune, near Paris.)

Perfectly free from all adulteration, this Chocolate recommends itself
every one.

To those in health as an agreeable and highly nourishing Breakfast
Beverage.

To Invalids for its unequalled Restorative and Invigorating Properties.

To all, even the most Delicate, as containing nothing which is INJURIOUS.

Also sold in a great variety of forms, for eating at Dessert. Annual
Consumption exceeds 5,000,000 pounds.

Sold everywhere.

23, HENRIETTA-STREET, COVENT-GARDEN, LONDON.

James's Fever Powder, 4s. 6d. per bottle; packets 2s. 9d. each.

Prepared and sold by J. L. KIDDLE, 31, Hunter-street, Brunswick-
square, London.

This Preparation has been so extensively employed by the Faculty,
and its merits so universally acknowledged by the public at large, as to
render all further remark on the part of the Proprietor unnecessary. To
be had of all Wholesale Druggists.

Treloar's Kamptulicon:

COCOA-NUT MATTING,
AND OTHER DURABLE FLOOR COVERINGS,
67 LUDGATE HILL, LONDON,
Three doors from the Railway Bridge.

HIPPO, SMILAX, AND MORPHIA LOZENGES.

We invite the attention of the Medical

Profession to the combination of these active medicinal
agents with demulcent adjuncts in these Lozenges, in such cases as
their use would be considered judicious, being so palatable that many
patients who might refuse to take any medicine in a liquid form or
otherwise would be induced to make use of them. Each Lozenge con-
tains 1-32nd of a grain of muriate of morphia.

WHITE & CO., DRUGGISTS,
32, WEXFORD-STREET, DUBLIN.

N.B.—None genuine unless with our label stamped with our trade-
mark—viz., a Stag's Head on a Mural Crown.

TO PHYSICIANS, SURGEONS, AND DRUGGISTS.

Brown's Cantharidine Blistering Tissue,

prepared from pure Cantharidine. An elegant prepara-
tion, vesicating in much less time than the Emp. Lyttie, P.L., easily
applied and removed, and will not produce strangury or troublesome
after-sores. It has received the sanction and commendation of many
of the most eminent practitioners in the kingdom.—In tin cases, con-
taining ten feet, 6s. 6d.; and small cases of five square feet, 3s. 6d. each.
BROWN'S TISSUE DRESSING.

An elegant, economical, and cleanly substitute for all ointments as a
dressing for Blisters, Burns, &c., and may be called a companion to the
above.—In tin cases, containing twelve square feet, 1s. 6d. each.

Sole Inventor and Manufacturer, T. B. BROWN, Birmingham.
Sold by all Wholesale and Retail Druggists and Medicine Agents
throughout the British Empire.

Dublin MESSRS. BOILEAU and BOYD, 91, 92, & 93, Bride-street.

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

Original Communications.

ON THE POLARIZATION OF LIGHT BY THE
OCTAHEDRAL CRYSTALS OF
OXALATE OF LIME.

By GEORGE W. BALFOUR, M.D.

(Read before the Medico-Chirurgical Society, on Wednesday, 5th
July, 1865.)

THOSE who are acquainted, and who is not, with the writings of Golding Bird upon urinary deposits, are aware that in spite of the failure of chemical tests to establish any decided difference, he still regarded those dumb-bell crystals, so frequently found associated with the ordinary octahedral forms of oxalate of lime, as possessing a different chemical constitution from them, solely because they polarized light, while the octahedral crystals apparently did not do so. His argument was that oxalate of lime belonged to the regular or cubic crystallographic system, crystals belonging to which never possess double refraction, and hence exert no influence upon a plane polarized ray of light. Since Golding Bird wrote, the argument has also been frequently put conversely—the octahedra of oxalate of lime do not polarize light, therefore they belong to the cubic system. Nay, the non-polarizing property of the octahedra of oxalate of lime seemed so decided, that Dr. Beale, in the first and second editions of his work on the "Microscope in Medicine," declared generally that "substances which crystallize in the octahedral form do not possess this property,"* being apparently compelled to make this false generalisation by the fact of his having just previously stated that the octahedra actually belonged to the quadratic system, one of their axes being much shorter than the other two. Many other authors—among them Prout, Wollaston, and Funke—were also aware of the fact, that the system in which the oxalate of lime crystallizes is not the regular cubic system; but it seems to have been reserved for Dr. Thudichum to make the natural deduction, that if they do not belong to the cubic system they ought to polarize light, and forthwith he set about making them do it. With the prismatic and other more or less amorphous forms he was, of course, easily and perfectly successful; but in regard to the octahedra he states that they "have a very faint polarizing power, which can only be brought out fully by reflecting a ray of the sun through the crystal lying between the two Nicol prisms, and excluding from the eye every other light but that coming from the crystal in the microscope."† Stating correctly enough that the reason why these octahedra polarize "faintly," as he calls it, is that they float generally with their principal axis nearly perpendicular, and that crystals polarize less the more parallel with their principal axis, or axis of (no) double refraction, the rays of polarized light are which pass through them, adding that this is one reason why these crystals polarize but faintly when ordinarily illuminated, though no doubt other reasons co-operate in producing this effect.‡ Now, one reason, if efficient, is certainly perfectly sufficient, and I can conceive nothing more so than a law which light cannot be forced to break, even by increasing its intensity. At Plate V., Fig. 4, of his work on the "Pathology of the Urine," Dr. Thudichum has represented two figures of an octahedral crystal:

of oxalate of lime, as supposed to be seen by polarized light. In the one figure, that to the right, the crystal is stated to be seen edgewise; and the other, if correctly drawn, has its principal axis also off the perpendicular. Both ought, therefore, to have exhibited distinctly the phenomena of polarization. It is just as evident, from the deep shadows represented upon the sides of both these figures, that a quantity of diffused light had, somehow, obtained access to the field of the microscope, and that the crystals are seen more by its aid than by that of the polarized rays transmitted, which, indeed, seem to be neutralised to a large extent by this stronger sidelight. In his lectures upon "Urine and Urinary Deposits," Dr. Beale has corrected the mistake into which he had fallen in his work on the "Microscope," and has stated that now he finds that octahedral crystals of oxalate of lime, mounted in Canada balsam, do polarize, even with a good artificial light.* In the absence of any figures, it is, of course, impossible to criticise this statement; I can only say from the flatness of the ordinary octahedral crystals, and the readiness with which, when displaced, they resume their usual position when floating—viz., with their principal axis perpendicular, I have I have found it impossible to maintain them out of this perpendicular sufficiently long to enable the balsam to harden round them, and thus detain them in a proper position for observing the phenomena of polarization; and, therefore, though I have often seen these crystals polarize light during the process of mounting them in Canada balsam, I have not hitherto been able to procure a specimen which would do it after the mounting was complete, for I need not add, that the medium in which these crystals float, whether urine, water, or Canada balsam, makes no difference in regard to the maintenance of the law which provides for the non-transmission of those rays of polarized light which are parallel to the principal axis of the crystal. When experimenting upon this matter I found, of course, that both in urine and in water the octahedra turned over so rapidly that it was impossible to observe with any distinctness the phenomena of polarization, and at the same time that Canada balsam was both sticky and troublesome. It then occurred to me to employ glycerine as the fluid in which to float the octahedra, first removing all the water about them by means of a pipette. The results were most admirable; the glycerine was sufficiently fluid to be easily workable, and yet sufficiently dense to enable me to displace the octahedra with the greatest ease, while they turned so slowly as to exhibit all the phenomena of polarization in perfection, and that even in the faintest light—natural or artificial—by which they could be seen. From the distinctness of the phenomena and the ease with which the experiment can be performed, it is obvious that henceforth no argument in favour of dumb-bell crystals being composed of oxalurate, and not of oxalate of lime, can be based on the statement that the octahedra do not polarize. In proof of this I append a few representations of octahedra, seen by polarized light. In Figure 1 are given ten representations of octahedra of oxalate of lime thus observed; the eleventh representation is that of an amorphous mass of the same. In Figure 2 the representations refer to the same octahedra indicated by the corresponding numerals in Fig. 1, and represent them, as seen by polarized light, with a bright field, in precisely the same position in which they were when depicted on the dark field. This position was always carefully verified by again turning round the polarizer, so as to make sure that the crystal had retained its positions.

PAPERS ON DERMATOLOGY.

No. 1.
SYCOSIS.

By T. W. BELCHER, M.A., M.D. Dub.,

FELLOW AND CENSOR, KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND; PHYSICIAN TO THE DUBLIN DISPENSARY FOR SKIN DISEASES; AND EDITOR OF "NELIGAN ON DISEASES OF THE SKIN," 2ND EDITION, 1866.

C. B., ætat. 55, a Dublin newsvender, came to me at the Dispensary for Skin Diseases in Bishop-street, on the 18th of November, 1864, with a remarkable and comparatively rare affection of the face.

This was an eruption covering the parts on which the beard, whiskers, and moustache usually grow; and the patient stated it to be of long standing. He did not appear ever to have had syphilis.

The eruption in question was circumscribed in extent, as already noticed; and it had commenced by the appearance, round the roots of the hairs, of slightly inflamed-looking elevations, on which a dry greyish scurf shortly was produced. This scurf grew rapidly, and by the constant use of the razor it became so aggravated that conical pustules formed on the seat of injury, thus masking, as has been often remarked, the original features of the disease.

At the above date (18th November, 1864) the disease was in the state just described in some places, while in others it had progressed further, causing heat, pain, tension, and swelling, maturation and bursting of the pustules, and the consequent formation of hard brown scabs, which closely adhered to the surface.

I directed him to take half an ounce of cod-liver oil three times daily, and to apply camphor and chloroform ointment to the surface.

On the 25th November he seemed to be much in the same state as before. He was now directed to take some pills to remove constipation, and to rub a diluted nitrate of mercury ointment to his chin and face; also to poultice the diseased surface on the night before his next visit.

December 6:—He has now cleared away all the scabs, and the pustules have also disappeared, save a few undeveloped ones round the roots of some of the hairs. He has some bald, circular, ringworm-like patches on the cheeks and chin; red stains mark the site of the previous morbid growth; the hairs of the beard, which, in some places, has grown of late since he ceased to shave, are thick and slightly bent; but they cannot be pulled out without pain.

Treatment.—Repeat pills and ointment.

9th. The surface is now dry, and of a dusky red colour.

Repeat pills, and apply strong tincture of iodine to the skin with a camel's-hair brush.

13th: He is now doing well.

Continue application of iodine, and the codliver oil which he has taken throughout.

23rd: He has been absent for some time in consequence of his having taken a severe cold; however, the disease is much better. Pergat.

20th January, 1865:—He has done nothing since last attendance, and although the disease is much better than it was when he first came to me, it has, to some extent, regained its ground during the last month.

Treatment.—Continue codliver oil, and application of iodine, with occasional use of diluted nitrate of mercury ointment; poultices and purgative pills.

24th: Much better. Pergat.

27th: Still improving.

31st: He does tolerably well now; and the remedies have plainly done much of their work.

From this time forward he ceased to attend at the dispensary, and as he had had a bad attack of bronchitis, I feared he might have died; but I was glad to see him alive, and to all appearance cured of this affection, in July, 1865. At this time he retained the ringworm-like patches and the

dusky red, hard looking appearance of the the skin of his face.

From examination of the disease in this case, and from the symptoms already detailed, I am of opinion that it is a specimen of the parasitic affection known as sycosis. This disease is rare, and the cases are still more rare, in which it occurs on the upper lip. Its causes are obscure; the only manifest one, and that as in this case, usually assigned, being the transmission of the parasite by means of a razor. In my edition of "Neligan on the Skin" (p. 420), it is noted that M. Foville witnessed the transmission of sycosis to several individuals in this way. Dr. Neligan, however, also stated that the irritation produced by shaving, and by the use of acrid shaving soaps, in persons of a delicate skin, while they could not produce the disease, yet could aggravate it very much, and also could cause other skin affections, such as acne, impetigo, ecthyma, and syphilitic eruptions, with which sycosis is often confounded. The diagnosis in difficult cases can generally be determined by aid of the microscope, but sometimes this is not necessary, the character of the crusts, the thickened state of the integuments, the development of conoidal pustules, and the ringworm-like, bald patches on the places where the hair should grow, are, for the most part, sufficient to decide the question.

The absence of the fungus is not conclusive evidence against the existence of parasitic disease; for, as Dr. Tilbury Fox remarks ("Skin Diseases," p. 258):—"It is probable that the fungus, which is the cause of the primary irritation, is more or less destroyed by the pus which forms in the follicle, the tissues, nevertheless, continuing inflamed, in consequence of the peculiar structure of the part."

The fungus here referred to (an account of which is given on pp. 419, 420, of my edition of Neligan) is the microsporion mentagrophytes. M. Bazin looks on this affection as simply a variety of ringworm; and such is also the opinion of M. Hardy in his most recent work ("Leçons sur les Maladies de la Peau," Paris, 1863, 2ième edit.) He calls it "trycophyite syco-sique," and he agrees with the opinion already quoted—that its single efficient cause is contagion, and that it is frequently transmitted by the use of the razor.

Most modern foreign writers on cutaneous diseases recommend epilation for the cure of this affection. In the present case I commenced to try it, but had to desist at the request of the patient, who did very well without it. As a rule I do not adopt epilation in parasitic diseases, as I have found that the morbid growths can often be removed without it.

THE MEDICAL COUNCIL.—The parliament of Medicine is summoned to meet in London on May 15, and will probably sit through Whitsun week. The Medical Council is a highly-paid, deliberative body, representing the Colleges of England, Scotland, and Ireland. Each member receives ten guineas a-day during the session. Its deliberations have generally lasted a week, and cost over £1500 in fees. Fortunately for the fund which has to provide the fees (they are drawn from the pockets of the Medical Profession), most of the members are in lucrative practice, and lose by the arrangement; otherwise speeches costing some £5 an hour might be unduly prolonged, and would be open to even more severe criticism than they now receive. There is one service which the Medical Council might render which would be welcome to the public generally as to the Doctors. They would confer a great benefit if they could persuade the Government to introduce such an amendment of the 40th clause of the Medical Act as should really prevent unlawful practice by medical pretenders, and enable all men readily to distinguish between legal and illegal Practitioners. This the Medical Act now professes, but fails to do.—*Pall-mall Gazette.*

LUNATICS.—On Saturday last, Richard Harris and John Aires were indicted for illegally receiving a lunatic into their respective houses for profit without a licence. It was proved that they had acted in ignorance of the law and the judge discharged them upon their own recognizances et come up for judgment when called upon.

Hospital Reports.

MATER MISERICORDIÆ HOSPITAL.

A CASE OF ASCITES WITH ANOMALOUS THORACIC SIGNS.

(Under the care of Dr. HAYDEN.)

Reported by Dr. BELCHER.

For the details of the following very interesting case I am indebted to the kindness of Dr. Hayden, who invited me to see it, exhibited to me its various features, and placed his case-book at my disposal. The following record is given, for the most part, in his own words:—

Ellen Moore, aged 42, married at 15, and the mother of fifteen children, was admitted into hospital on the 3rd of October, 1865. She states that her health had been good until about twelve months ago, when, as she supposes, in consequence of the stoppage of her menses, she coughed up large quantities of dark blood. This occurred on several occasions, and she felt on each occurrence of it a tickling in the chest and a feeling as if the blood proceeded from the left side. There has been no recurrence of this hæmoptysis for several months past.

Shortly after the first appearance of blood, as above noted, her feet became swollen, and then her abdomen, but never the face. She has not been jaundiced, and cannot trace the abdominal swelling from any particular part of the abdomen.

When first seen by Dr. Hayden there was ascites; the abdomen was very large, but there was not any œdema of the feet or of the face. The patient was emaciated, the face being of a dusky, but not of a jaundiced, hue. The pulse was quick and weak; she also had cough, with mucous expectoration; the kidneys were acting indifferently, but there was no albumen in the urine. She was subject to intercurrent attacks of diarrhœa; the heart's action and sounds were normal.

After some weeks in hospital it became necessary to perform paracentesis abdominis, owing to embarrassment of the respiration. On this occasion between five and six gallons of thin clear fluid were removed; about three weeks later the operation was repeated, and with a similar result.

For some time previous to the performance of paracentesis she had complained of pain in the left side, and occasionally in the right; after the last tapping, however, the pain in the left side became more urgent. She described it as sharp and shooting, and extending from the region of the left kidney upwards through the left side of the chest. On one occasion she coughed up a large quantity of puriform matter, which Dr. Hayden thought at the time might have proceeded from an abscess of the liver discharging itself through the lung.

About the 1st of December, 1865, the left side of the chest became dull inferiorly, whilst the upper part yielded a somewhat tympanitic sound. The dullness gradually extended upwards, whilst the heart became displaced towards the right side, and respiration became more embarrassed than before.

Dec. 12th, 1865: She now can lie only on the left side; the pulse is 104, and weak; respiration, 42; she also suffers from loss of appetite and want of rest. The left side of the chest is dull from the second rib downwards in front; over this region respiration is bronchial (transmitted?) and unaccompanied by râle. Above the second rib resonance is highly tympanitic, and here the respiration and voice are amphoric.

22nd: For some days past she has been perspiring profusely, and the respiration has become so much embarrassed that paracentesis abdominis was again performed on Monday, December 18th, when about five gallons of clear and thin fluid were drawn off. She has not experienced much relief from this operation. The pulse has since varied from 108 to 90, which is the rate to-day, and

pain of a most urgent character is still complained of. This pain, she states, commences "about the left kidney," and shoots up through the left side of the chest and down the left arm. Pressure over any portion of the left side in front, especially below and outside the left mamma and beneath the left clavicle, cannot be borne. The left side of the chest exceeds the right in girth by two inches. It is unusually dull, the dullness being modified by gastric tympany as high as the nipple in front; but from the nipple to the second rib dullness is absolute; from the second rib to the clavicle it has an imperfect tympanitic ring. Over the entire of the left side vocal vibration, which is present on the right side, is entirely absent. In front, from the clavicle to the second rib respiration and voice are amphoric, especially towards the sternum. Over the remainder of the front respiration is entirely absent. Posteriorly, over the whole extent of the side respiration is bronchial, and this is the case as far forward as the middle of the ribs. The heart pulsates immediately to the right of the sternum at the normal level, and the anterior dullness extends to the middle line of the sternum.

The spleen can be distinctly felt by palpation; it is somewhat enlarged, and of stony hardness; it is likewise exquisitely tender to pressure.

No perceptible enlargement of the liver can be detected; but in the region of the right lobe a somewhat irregular elevation is felt, extending obliquely downwards and to the left side for about two or three inches.

This is tender to the touch, and resonant on percussion. Another similar irregularity is found to the right of the former.

The appetite is so good that the Sister in charge declares that the patient took an excessive meal of meat yesterday, and that this excess sickened her; pulse 90; respiration 30; sputa resembled gum-water. She was ordered wine, about six ounces, and whisky punch in small quantity; also an opiate plaster over the left side.

Dr. Hayden did not consider the diagnosis of this intricate case as quite clear at this stage; he was under the impression that there was malignant disease of the spleen, and, probably, also of the left lung.

26th: Pulse 96, and good in volume; respiration 30; tongue clean; appetite pretty good; the diarrhœa, pain in the chest, and cough are less troublesome. The left side of the chest moves in respiration in a scarcely less degree than the right. The movement is localised in the third and fourth intercostal spaces in front, and is very obvious. The left side of the chest, measured below the nipple, exceeds the right in girth by one inch; vocal vibration is absent before and behind from the second rib downwards; resonance is hollow from the clavicle to the second rib; and here the respiration is tracheal or cavernous, especially behind the sternoclavicular joint. From the second rib to the lower edge of the third it is less clear, but still of modified hollow ring, and here the respiration is feeble. From the lower edge of the third rib dullness is complete and all respiratory sounds, save transmitted and distant bronchial sounds, are absent.

Dullness is complete behind from the angle of the scapula downwards. Here respiration is bronchial; at the inferior angle of the scapula it is blowing; and at this point vocal resonance amounts to pectoriloquy. There is likewise vocal resonance below this level, but it is less pronounced. From the angle of the scapula upwards dullness is somewhat less, but respiration and vocal resonance are the same as below this point. Over the entire of the left lung to-day, for the first time, there is evidence of softening in a coarse muco-crepitus, and under the left clavicle, when the patient coughed, Dr. Hayden heard a faint metallic tinkle.

The factor of the breath is very offensive; the fluid is re-accumulating in the abdomen; the tenderness on pressure under the left clavicle is considerable.

The opiate plaster over the left side has given her much relief; there is a scarcely perceptible enlargement of the

superficial veins of the left side of the chest; the veins of the neck on that side are not distended.

Dr. Hayden still regards the diagnosis of this case as obscure; and entertains the idea that it may be malignant disease of the left lung; in favour of which opinion are the following facts:—

a.—The variability of the physical signs; the acute shooting pain in the left side and extreme intercostal neuralgia.

b.—The absence of evidence of hepatic disease sufficient to account for ascites, and the consequent probability of malignant disease in the abdomen sufficient to cause it.

c.—This last probability is rendered the stronger by the acute pain felt for some time past in the left lumbar region, and by the actual condition of the spleen, the former hæmoptysis and the slight engorgement of the left superficial thoracic veins.

Against this supposition are:—

a.—The absence of cancerous aspect of the patient;

b.—The trifling engorgement of the thoracic veins;

c.—And the uniformity of the left thoracic enlargement.

If non-malignant, Dr. Hayden thinks it may be pneumothorax with effusion of pus, the result of the bursting into the pleura of a tuberculous abscess of the lung.

In favour of this view may be urged: the former hæmoptysis, the tracheal (cavernous) breathing, and metallic tinkling under the clavicle, and at the angle of the scapula, where the breathing and voice are somewhat fistulous.

Further, Dr. Hayden thinks it may be serous or purulent effusion, with adhesion of the lung above and behind, and tuberculous or gangrenous softening of that organ. It may be empyema with cancer of the lung; and, in regard to the two last suppositions, he refers to the displacement of the heart to the right side, and to the softening of the lung already noted.

27th: From the clavicle to the second rib percussion sound is of a *normal character*; but a shade clearer than on the opposite side; and here respiration is less tracheal, with mucro-crepitus; below the nipple dullness is complete, and no respiration sound of any kind can be heard.

February, 1866: Paracentesis has been performed a fourth time, and with about the same result as on former occasions.

27th: *Long* after tapping. From the clavicle to the second rib, on the left side, is now tympanitic; below it is dull. Respiration and voice are bronchial from the clavicle to the second rib; likewise bronchial, but less so over the remainder of the left side anteriorly.

28th: There is dullness now where tympanitic resonance had been on the previous day.

March 2nd: Tympanitic resonance again from the clavicle to the second rib, as far horizontally as the left margin of the sternum; from the upper edge of the second rib to the upper edge of the third resonance is similar in quality, but less tympanitic; from the third to the base percussion is dull. Respiration and voice are bronchial throughout in front, more so from the clavicle to the second rib. The heart pulsates under the right margin of the sternum inferiorly.

15th: Paracentesis again performed for the fifth time, and eight gallons of amber-coloured serum, containing much albumen, were drawn off. The patient is weak, but bore the operation well. Resonance has been clear but *normal* in the upper left (to third rib) for several days. She has had ammonia and chloric ether, which caused tenesmus, and was afterwards stopped in consequence of it. The tenesmus was relieved for the most part by her taking laudanum and liquor bismuthii.

16th: Peritonitis of a sub-acute form, with much flatulent distension of the abdomen, has now supervened. She vomited repeatedly since last night. The features are pinched and shrunken; pulse quick and weak; tongue dry, but not coated.

℞ Pulv. opii, gr. i.

Calomel. gr. ss. M.

Ft. pilula sumat. talem i. Stia quaque horâ. Warm

bran poultices to abdomen, half-ounce of brandy to be given in water frequently, and beef-tea.

10th (date of my visit): The left side of the chest is now resonant throughout in front. This is only exaggerated normal resonance. Here also is a painfully sharp vocal thrill. The patient is very weak, has sordes on the teeth, and cannot survive many days.

27th: Pulse 102 and weak; she is much emaciated; has copious night sweats; severe pain in hypogastrium and left iliac fossa; tenesmus and re-accumulation of fluid in abdomen.

31st: The patient is exceedingly weak, the tongue dry, the stomach and bowels irritable, the heart has returned to the left side, and now pulsates to the inner side of the left nipple.

Proceedings of Societies.

OBSTETRICAL SOCIETY OF LONDON.

MARCH 7, 1866.

Dr. BARNES, President.

THE following gentlemen were elected Fellows of the Society:—Drs. G. B. Brodie, John Easton, C. B. Fox; Messrs. N. Arent, R. Blagden, J. H. Bryant, Thomas Dane, W. Dewsnap, R. A. Elliott, John Loane, W. Soper, H. Winterbottom. Prof. Retro Laggati (of Milan), and Dr. Theodore Hugenberger (of St. Petersburg), were elected Honorary Fellows.

Dr. TYLER SMITH showed a new Vaginal Speculum made for him by Messrs. Weiss. He considered it much more convenient than any other known to him. It was made in the form of a double duck-bill, the ends being in close apposition. The nuisance of having a plug for the sake of introduction was done away with.

The PRESIDENT stated that he had had a rod made after the fashion of the uterine sound for the purpose of cauterizing the cervix uteri in the manner described by him at the last meeting.

Mr. BAKER BROWN, jun., exhibited a little boy, ten weeks old, born with amputated arms and legs, but perfect in other respects. On one of the thigh stumps there was an appearance of toes, and on each of the stumps of the upper extremities was a distinct nipple.

Dr. MADGE showed a specimen of fibrous tumour of the uterus. It measured fifteen inches in circumference, and weighed nearly two pounds. It had a pedicle, which was attached to the posterior wall of the uterus.

Dr. BARNES exhibited a specimen of an encysted fetus, which had been removed at the patient's death, forty-three years after its escape into the abdominal cavity. He also showed a mummified fetus, which had been expelled after the birth of a full-grown child.

Dr. BRAXTON HICKS exhibited a specimen of the echinococcus, which had been discharged from the vagina.

Dr. WALKER, of Peterborough, read the history of a case of ruptured vagina during labour.

Mr. BAKER BROWN read a paper on the

USE OF THE ACTUAL CAUTERY IN OVARIOTOMY.

The author observed that, on February 1st, 1865, he placed before the Society his first case of completed ovariectomy in which the pedicle was divided by the actual cautery. Since then he had published ten or eleven more in the *Lancet*; and now he wished to relate his last eleven cases, and make some remarks on the use of the actual cautery. In the eleven cases the operation was completed, and all recovered. Mr. Baker Brown found that, in a few of the cases, the cautery was not sufficient alone, he having to ligature several vessels in the adhesions; and in Case 6 the artery, which was bleeding, was from a very fat mesentery, and the superabundance of fat prevented the seared edge from puckering. He considered it highly necessary to have a properly-made clamp; also, it was ad-

visible that the iron should not be too hot, a simple red heat being best, so as not to hurry the process of separation, but to bruise the pedicle by cutting it off slowly, and afterwards care must be taken not to disturb the stump. On one occasion, the author being anxious to see if the vessels were safe (after the cautery), gently rubbed the edges with a towel, when the crust was broken, and a small vessel bled. Of twenty-three cases of completed ovariectomy, the author had lost but two. He thought it must appear evident that this success had arisen from the use of the actual cautery.

Mr. BROWN then presented a cyst and pieces of omentum from a patient operated on the day before, which showed that the whole omentum was so fat that the cautery would not act safely on the adhesions. In such cases it was better not to attempt its use. The pedicle itself was safely removed by the cautery clamp.

Dr. ROUTH read a paper on

A CASE OF FIBRO-CYSTIC DISEASE OF THE UTERUS WHICH WAS MISTAKEN FOR OVARIAN DISEASE.

It occurred in a woman aged twenty. There were two large abdominal fluctuating tumours united by a large solid mass. These were diagnosed as multilocular ovarian disease by Dr. Savage, Dr. Greenhalgh, Sir W. Fergusson, and Dr. Routh. All advised operation except Dr. Greenhalgh, who recommended delay. She was operated upon on Nov. 16th, 1865. There were no adhesions of any consequence. The tumour was freely movable on the right side. On the left, it was bound down by the usual ligaments, and had become very dense and unyielding. Extirpation was thus impossible. Portions of the omentum were removed by actual cautery. The larger right cyst was punctured, and emptied of a quantity of pus, and the abdominal wound brought together. The patient scarcely rallied, was constantly sick, and died, after evidence of internal bleeding, in thirty-four hours.

The post-mortem examination revealed that all the cysts were full of blood, vessels having given way in them, probably through the vomiting. The actually cauterized surfaces were quite shrivelled, and free from even an appearance of blood. The whole fundus of the uterus was fibro-cystic.

The importance of this case was brought out in the error of diagnosis. All the usual symptoms of fibroid disease were absent—namely, early fibroid hardness of tumour; absence of flooding; increased length of uterine cavity; absence of tubular soufflé; and previous exploratory puncture would have only given exit to pus. Secondly: Owing to numerous vascular trabeculae in the tumour, death might at any time have resulted from simple puncture with the trocar. Thirdly: It proved the great efficacy of the actual cautery, even in a case of constant sickness following operation.

Mr. SPENCER WELLS said he fully admitted that in some rare cases it was very difficult, perhaps impossible, to arrive at an exact or positive diagnosis as to the nature of an abdominal tumour; but he contended that in the great majority of cases—in at least nine out of ten—it was quite possible to arrive as near the truth in this as in any other department of surgery. He admitted most fully that men of great experience, after carefully examining a case, would sometimes find it impossible, even with the help of an exploratory incision, to make a positive and complete diagnosis. In such a case as that narrated by Dr. Routh, the exact nature of a tumour might be doubtful even after its removal. But such cases were few and far between, and by no means opposed to the rule that in a large majority of cases of ovarian and uterine disease a very accurate diagnosis might be made. With regard to the use of the cautery in ovariectomy, the cases brought forward certainly proved that we had been taught an additional and successful mode of dealing with the pedicle. But they also convinced him that it should be an exceptional and not a general method. The number of cases in which

ligatures had been also required, the accounts of the melting and flaming fat, the care required as to the precise temperature of the irons, the slowness of the searing, the effects of disturbing the eschar, and the very frequent supuration in the abdominal wall, were very unsatisfactory. And the argument that because out of twenty-three cases only two had died, therefore this success was due to the use of the cautery, was clearly untenable; for it was a curious fact that of the last twenty-two cases of ovariectomy in which he (Mr. Wells) had been able to secure the pedicle by a clamp, only two had died, and one of these lived twelve days and died of cancer of the peritonium, which was not detected before the operation.

Time not admitting of further discussion or reply from the authors of the papers, the meeting adjourned.

SURGICAL SOCIETY OF IRELAND.

MARCH 16TH, 1866.

Dr. WILMOT in the Chair.

- 1.—SKELETON AND CAST OF A FŒTUS SHOWING A LARGE SPINA-BIFIDA EXTENDING FROM OCCIPUT NEARLY TO THE SACRUM.
- 2.—CAST OF A SPINA-BIFIDA IN THE LUMBAR REGION, WITH NOTES OF THE CASES.

Mr. H. G. CROLY stated that he was indebted to Dr. John Partington Gray of Kilgobbin, for the two cases from which the beautiful casts were taken for the museum by Dr. Barker, the Curator. He (Mr. Croly) dissected the fetus from which the first cast was taken, and had the able assistance of his friend Dr. Macalister. He then read the notes taken by him at the time:—Features natural; no neck visible; chin and sternum on one plane; left external ear buried in a deep groove; a large tumour (spina-bifida) on the posterior surface, extending from the occiput nearly to the anus; extremities fully developed.

Dissection.—The tumour, which is the size of a cocoa nut, is covered with integuments and fat. On dissecting off the skin the cyst is found to be thick and rather pyriform in shape, lobulated, and has blood-vessels ramifying on its surface. The sac is divisible in three layers—viz., an external or fibrous, a middle or adipose, and an internal or vascular of great strength. On opening the latter a quantity of brain substance with clotted blood was observed in the interior. The cavity communicated through a fibrous opening with a small thin sac situated at the left side of the cervical region. The sac also communicates with the cavity of the cranium through a large opening at the left side of the occiput. The ribs at the left side radiate from the occipital bone. There is a left palate; no sternal origin to the left sterno-cleido mastoid muscle; brain fully developed; no spinal canal; abdominal and thoracic viscera natural.

Cast 2.—Taken from a child named James Ryan, aged two months, admitted into the City of Dublin Hospital in July last. He ascertained from Dr. Grey that the child died of convulsions on the 21st of August following. The tumour in this case was partly covered with integument.

Mr. DARBY exhibited a

NEW-BORN PIG (ONE OF A LITTER OF TWELVE)

having the hind quarters of two pigs, both males, united at the loins into one body with one pair of forelegs and one head with two pairs of ears. Dr. John Barlow had kindly opened the thorax and abdomen, but no dissection had as yet been made. There was one heart in the centre and in front. It appears as if another heart corresponding in size can be felt lower down and close to the spine. The lungs are irregular, and appear larger and with more lobes than are comprised in one pair, but there does not appear to be two distinct pair. There is but one abdominal cavity and but one umbilical cord. He, in the

absence of more interesting matter, brought this case, as he had on more than one previous occasion brought other monstrosities under the notice of the Society—not as a mere curiosity, but in the hope that the exhibition of such abnormal creatures may lead to their being classified, and thus the vulgar error of supposing that impressions made upon the minds of pregnant women exercised an influence upon the formation and growth of the fetus in utero—impressions which frequently caused distress—may be corrected. He thought all abnormalities of this nature might be embraced within three classes or heads, viz.:—Excess of development, arrest of development, and cases in which adherence to the normal formation or type of the inferior animals are found to present. Instances in each of these classes are abundant, and he felt that the subject, if well worked out, would most probably lead to results such as he hoped for.

CANCER OF THE PENIS.

Dr. FLEMING exhibited a portion of the penis removed within the last few days from a patient in the Richmond Hospital. The subject of it was a countryman of the farmer class, was aged about 55 years, and had always enjoyed good bodily health. He had never been exposed to the venereal disease, was married, and had a large family. He stated that about eight or ten months back he felt some pain and uneasiness in the situation of the frænum, and remarked that he could not expose the glans as previously, that the organ itself became full and congested, and that a hardness and swelling took place, which bulged out the prepuce, and latterly protruded through its orifice, interfering occasionally with the free escape of the urine. There was some discharge accompanying it, but not very much; it was fetid, but free from any bloody tinge. He suffered inconvenience more than absolute pain, except during the erect state of the organ. On examination, complete and permanent phimosis presented itself, the integuments of the penis retaining their natural colour. A solid, hard, and irregularly knotted feel was communicated to the fingers in the region of the frænum, and through the orifice of the prepuce, and attached to its inferior surface, a warty growth about the size of a small walnut protruded, having all the prominent features of epithelioma. Here, alone, was there any abnormal connexion between the prepuce and glans, a probe elsewhere passing freely around. The hardness noted extended about an inch along the under part of the urethra, where it was fully circumscribed. The inguinal glands were free from any disease. The malignant nature of the affection and its removal were decided upon. It was effected in the ordinary manner, with the additional provision of a strong curved forceps, whereby the body of the penis was firmly held behind its line of section, and thus retraction of the organ to the extent which usually occurs was prevented, and hæmorrhage was commanded until the usual vessels were secured. In this specimen all the essential features of epithelioma were obvious, and required no special description. It was in a great measure limited to the vicinity of the frænum, the under part of the glans being identified with it to the extent of about an inch. Dr. F. directed attention to the caution requisite in the accurate diagnosis of the disease of cancer of the penis, as otherwise serious mistakes might be made. He had perfect recollection of a case which occurred many years back in his practices, where fortunately only the prepuce was removed for a growth considered to be malignant by most eminent authorities. The subject was a gentleman, aged beyond 60 years, yet in the reparative stages of the wound, unequivocal syphilitic symptoms set up, which altered altogether the original opinion entertained. Another case was fresh in his memory, where the whole penis was most unwarrantably removed in a young man for warty growths perfectly innocent in their nature.

CASE OF FIBRO CYSTIC TUMOUR.

By F. J. DAVYS, A.B., L.R.C.S.I. & K.Q.C.P.I.,
I have the honour to lay before the Society this evening

a specimen of fibro cystic tumour removed from a female from whose arm, and in exactly the same position a similar tumour was removed in February, 1865. I exhibited that tumour here, and a report of the case appears in THE MEDICAL PRESS of March, 1865.

As it was suggested that the tumour was malignant, and as the Chairman requested that I should observe the progress of the case, I did so and found that in November last the tumour had grown again, and had attained the size of a small orange. She applied to me at my dispensary in Swords, stating she was unable to earn a livelihood, and requested to obtain her admission into St. Vincent's Hospital, where the tumour was shortly afterwards removed by Dr. Mapother. As it was movable and encapsulated, a single long incision sufficed for its removal.

The tumour, although altered somewhat by maceration in spirit, is, as you may remember, very similar to the one I exhibited last year, consisting externally of a firm fibrous capsule, and internally of fibro areolar tissue, the spaces of which are filled with a bloody serum.

I still regard the case as one which is now malignant, as the patient is, and has been always in the most perfect bodily health, and as she suffered no pain till the tumour became so large as to stretch the skin over it to an extreme degree.

Dr. DAVYS also exhibited a specimen of

SCIRRHUS OF THE BREAST.

By way of contrast it may be also worth while to exhibit a small specimen of scirrhus, which I removed from the left breast of a female aged 35, but very much older in appearance, residing within three miles of Swords. The patient, unmarried and never menstruated, applied to me on two or three occasions stating she suffered very great pain at intervals from a tumour in her breast, which had been forming in it since early in last summer.

Her means of living depended on the wages she received as an ordinary labourer in the field, on which occasions latterly the pain in the breast was intolerable. I recommended her to have the tumour at once removed, and as the cabins of the poor do not present facilities for the surgeon to use his knife even in trifling operations, I directed her to one of the hospitals, especially as she resided such a distance from my house. She decided on not going to hospital, and therefore I removed the tumour, by making a free incision extending to about two inches above and below the tumour. On removing the skin and fascia it was remarkable the firmness with which the tumour was attached to the pectoralis major muscle, and through it to the cartilage of the fourth rib. In this operation I obtained valuable assistance from my young friend, Mr. William Tobin, one of the students of this College, who happened to pay me a visit at the time.

The tumour is evidently, in my opinion, a scirrhus growth, from its hardness, napiform, and screeching sound which it emits on section.

A FEW OBSERVATIONS ON CHOLERA MORBUS,

By CHARLES TRENERRY, ESQ.,

SURGEON OF THE CIVIL HOSPITAL, GIBRALTAR, AND CORRESPONDING MEMBER OF THE SURGICAL SOCIETY OF IRELAND.

Much has been written, much has been said, and much less has been done, without yet arriving at a correct knowledge of the etiology of this terrible disease, therefore I will not presume to offer any theory or explanation of my own; but as regards the treatment I cannot avoid making the fact known that the local application of chloroform has proved a most valuable adjunct in my hands during our late epidemic of cholera, in relieving the distressing paroxysms of pain and cramps, which tend so greatly to exhaust the patient and terminate his life.

Such, in fact, was the relief produced, that many patients begged me to re-apply it even during their convalescence, and I feel convinced that the recoveries would have been greater if the unfortunate patients had not been sent into hospital in such an advanced stage of the disease.

Some of them only survived three, four, or six hours, and a few actually died before they could be got into bed, but the average duration was a little more than two days, and the recoveries averaged about twelve days.

One hundred and fifty-five cases of cholera were admitted into the Civil Hospital from the 19th of August, of which 87 were males and 68 females, averaging from 20 to 70 years of age, and of these it fell to my lot to attend 117 cases, out of which I lost 46 from the 9th of September till the 22d of October, when the disease appeared to have ceased.

The plan of treatment which I pursued was to have the patient placed between hot blankets, and a piece of lint saturated with chloroform applied to the pit of the stomach, and the evaporation prevented as much as possible by retaining a folded towel over it. The first impression was intense cold, soon followed by a burning sensation which generally alarmed the patient, and it was difficult to calm their fears unless I changed the application from side to side. Sometimes I applied it in the course of the median, sciatic, or crural nerves, and along the spinal column. Occasionally I caused them to inhale it (if the local means did not have the desired effect), but not to the extent of anæsthesia. The extremities were frequently rubbed with hot flannels, and sinapisms applied occasionally.

A mixture composed of brandy, aromatic spirits of ammonia, spirits of lavender and water, was given frequently, and cold water effervescent draughts and good beef tea allowed *ad libitum*, and as soon as a favourable reaction set in I directed five grains of trisnitrate of bismuth and a quarter of a grain of acetate of morphine, to be given in powder every three hours, and an occasional opiat enema; by which means the vomiting and diarrhoea were generally relieved. Afterwards tonics, astringents, and generous living completed their recovery.

CASES OF GUNSHOT WOUNDS.

Dr. FLEMING said that the rare occurrence of gunshot wounds in civil practice would render it excusable in him to bring before the Society some few cases which had fallen under his observation within the last six or eight months. One of the most interesting was that which created much sensation at the time of its occurrence—namely, the attempted highway robbery near this city, where the man attacked most gallantly defended himself, and the highwayman was secured. During the struggle of this man with his assailant, three shots were fired at him from a small American revolver. One of the shots took effect at the inner angle of the orbit, immediately over the superciliary ridge, and the other at the inner part of the upper third of the thigh on the opposite side. There was no evidence of any local effect from the third shot. He (Dr. Fleming) saw the man in twelve or thirteen hours after the occurrence of the injury. At that time he had recovered from the temporary shock. He saw him in consultation with Dr. Fenelly, who lived in the district, and on examination as to the nature of the injury, a wound was found at the inner angle of the brow, and another in the upper portion of the thigh, as specified, very near the track of the saphena vein. The man was capable of giving a very accurate description of what occurred, and it did not appear that he laboured under any very severe constitutional symptoms. He had no ostensible head affection, with the exception of a remarkably slow pulse. The man was removed to the Richmond Hospital, where he remained under treatment for three weeks. At the expiration of that time he left the hospital perfectly well, and he continues so. The wound at the inner angle of the orbit was very small, so much so that it required some little nicety of examination to find its situation, it being concealed by the hairs of the brow, so that it was not easily detected. The surrounding integuments were discolored from the effects of the powder, the shot having been fired quite close to the individual. In addition to the discoloration by powder, there was considerable fulness and congestion of the eyelids, so that it was impossible to examine accu-

rately the eye; at the same time he (Mr. Fleming) could see that the cornea was intact; there were, however, some particles of powder obviously impacted in the conjunctiva. He examined the wound carefully with a probe, and at a very short distance was able to detect a firm resisting substance underneath. The wound in the thigh presented an equally small contracted appearance. There was no discoloration there of any kind of the integuments. He examined carefully to see if there was any mark of exit of the balls, but no aperture of the kind could be detected in the case of either wound. There was some inflammation accompanied with œdema of the lids and swelling of the face, but as to much local suffering the man did not experience much. After a few days he thought it right to endeavour to ascertain what was the nature of the hard substance found over the superciliary ridge, which was naturally remarkably prominent in this man. Accordingly, he had recourse to the expedient adopted by Nélaton, of using a porcelain probe, and by this means distinctly ascertained the presence of a portion of lead in the wound. This expedient was most satisfactory, and he succeeded without much difficulty in removing three or four flakes or scales of lead, some of which had passed deep into the orbit. He found that the bullets used in this revolver weighed about 55 grains each, but the amount of lead removed from the wound was not so great, weighing altogether only 30 grains. The man left the hospital perfectly well, and the wound healed without any exfoliation of bone. He at all times complained of defective vision in the eye; this organ was examined with the ophthalmoscope in conjunction with Dr. Wilson, and no satisfactory evidence was discovered to account for the defect of vision stated to exist. As to the wound in the thigh, there was nothing unusual to remark. A good deal of inflammation supervened at one period, which was checked by the ordinary means. No bullet could be detected, no bullet escaped, and ultimately there was not to be found the slightest hardness or tenderness to induce the belief that the bullet had lodged in the muscles or elsewhere. He (Dr. F.) was under the impression that from the position in which the man was when the shot was fired, the bullet probably had not penetrated the shirt, but that it had driven in a portion before it, and that when the man stood up the bullet was drawn out in the fold. All were conversant with incidents which occurred during the Crimean and the American wars, and also in the Indian mutiny; they proved that such contingencies occasionally took place. He remembered perfectly a case of a gentleman who was cleaning his duelling-pistols, when one which happened to be loaded, went off; the ball passed through the palm of his hand, bringing with it a portion of a handkerchief which he was holding at the time, and this whilst being removed drew out the ball within it. At the time when duels were fought it was, as he (Dr. F.) had been informed, by no means unusual for the parties to wear a silk vest next the skin, in the belief that it might stop the ingress of a bullet. The result of this case was very satisfactory. As a precautionary measure to meet the contemplated defence of the prisoner with regard to the size of the pistol, and to ascertain its power, it was tested on a subject, by having it loaded with its usual charge, and fired as accurately as could be in the exact situation, and at the distance specified by the man assailed. The appearances of the aperture of entrance of the ball, as regarded the wound in the integuments and their discoloration, were found to be almost identical with those present after the injury; and from the examination of the skull, which was removed for inspection, it would be obvious that the pistol was capable of inflicting the most serious mischief.

The two other gunshot wounds which had come under his notice recently, were of a comparatively trifling character, and were remarkable for the insignificant amount of inflammation that followed. A boy of 17 had loaded a pistol, and finding there was no powder in the nipple, he endeavoured to push down the charge in order to force the

powder into the nipple. The pistol went off, two balls passed through the palm of his hand, and the amount of inflammation that occurred after such violence was hardly worth mentioning. It was principally confined to the locality of the wound, and the boy left the hospital after a fortnight, well, the wound having suppurated and granulated healthily. The other case was that of a person who was cleaning his revolver, not being aware that it was loaded. The revolver went off, the bullet passed under the annular ligament of the wrist and through the deep muscles of the forearm towards the elbow-joint, above which it was extracted. This wound healed without supuration of any moment. This was not remarkable, however, as every one who had read accounts of the late wars would remember similar results having occurred in cases of gunshot wounds.

Mr. STAPLETON observed that the probe tipped with china, and used by Nélaton on the occasion referred to, was in reality invented by an Italian.

Dr. DARBY said he saw a case of a man who was shot in a very peculiar way. He was blasting a stone in the breast of a ditch; the jumper was put in horizontally, and when the powder was being exploded, instead of going to one side, he ran down the field exactly in front of the hole, and was shot in the back. He had a piece of soft granite in the nape of his neck and another in his heel, and between 40 and 50 small grains, some merely specks, scattered over his back. The wounds were so small, little red marks here and there, that he (Dr. Darby) could not believe there was anything in them; but, on using a probe, he found there were foreign bodies underneath, and he took out one piece half an inch in length and irregular in shape, and removed a great many others, some not much larger than a pin's head. Not one of those wounds gave him the impression at first sight that anything had entered it. The man got well with an extraordinarily small amount of inflammation.

Dr. BANON said that he had met with a case presenting some peculiarities in Jervis-street Hospital. A poor lad presented himself with the symptoms of fistula in ano, and he stated that he had been operated on twice for fistula. He found that he was a pensioner; he had been in the army and served in New Zealand, and four years previously he was, he said, struck by a bullet. On examining him they found the mark of the entrance of a bullet in the lower third of the left thigh. They asked him if the bullet was ever sought for. He said it was, but could never be found. He (Dr. B.) then made an examination, and found a hard substance two or three inches from the anus under the glutinous muscle, which was the bullet that had remained there four years, causing this abscess. The case was interesting as regards the peculiar course the bullet took, the symptoms it caused, and the man not knowing it was in his body. The bullet was cut down on and taken out.

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS OF IRELAND.

21st MARCH, 1866.

Dr. BEATTY, President of the College, in the Chair.

ON the motion of Professor AQUILLA SMITH, the discussion on Dr. Belcher's paper on Diphtheria, read at last meeting, was deferred until after the reading of a paper on the same subject by Dr. Hayden.

Dr. HAYDEN then read a paper on

DIPHTHERIA,

in which he discussed chiefly the treatment of that disease by means of the hyposulphite of soda. The cases adduced were eight in number—viz., four in children, and four in adults. The doses in which the medicine was given varied from five to eleven grains, three times a day. The two first cases given were in children, aged eight and a half

years and two and a half years respectively. The former commenced to take the hyposulphite in fifteen-grain doses on the second day of illness; the doses were subsequently reduced to six grains, owing to the occurrence of diarrhoea. Wine and nourishment were given, and the child was convalescent on the thirteenth day. Both tonsils and the soft palate were covered with exudation, and a portion of the uvula was destroyed by sloughing.

The second child, who was not so seriously affected, commenced taking the hyposulphite in fifteen-grain doses on the first day of illness; there was much fever, fauces and pharynx covered with patches of exudation. The throat of this child, as likewise that of the former, was touched with a linctus containing tincture of myrrh, and on the seventh day the boy was convalescent.

The third case was that of a young man aged 30, who had been confined during the day in a close office, and slept in a badly ventilated and severed house. His illness commenced with chill, headache, nausea, and feverishness, followed by profuse night sweats, and total loss of appetite, with great debility. A person had been ill of some kind of fever in the same house, and been visited by the patient; what the character of fever was has not been made out. Five weeks subsequently throat symptoms were manifested for first time. The throat was now congested, and presented exudation. Hyposulphite of soda in eleven grain doses was given, and the patient was convalescent on the seventh day afterwards.

Case 4.—A man, aged 35, living under unfavourable hygienic conditions, had an attack of diphtheria. Six weeks subsequently, and whilst still in a state of great debility from the first attack, he had a second. The throat was now congested, and presented false membrane on both tonsils, &c.; there was great deafness and prostration. Hyposulphite in eleven-grain doses, wine, &c., and on the twenty-fourth day from this date patient left hospital quite restored to health.

The two next cases were those of boys aged 14 and 16 years respectively. Under the hyposulphite treatment the former was convalescent on the 7th day; the latter was lost sight of, but as there was no further report of him it is presumed he went on to recovery.

Case 7.—A man aged 70. Congestion of base of both lungs, engorgement of throat without exudation when seen. Patient was convalescent, but unfortunately having exposed himself prematurely had a relapse and sank very quickly. In this case the treatment consisted chiefly in stimulants; no hyposulphite was given, owing to irritability of stomach.

Case 8.—A man, aged 40, a few days before admission into hospital, complained of headache, nausea, shivering, and sore throat, pharynx congested, with follicular exudation, somnolence, and total loss of appetite.

Hyposulphite in ten-grain doses, chlorate of potash gargle, and 16 oz. of wine daily. The patient was attacked with erysipelas of right side of head and face, which was treated locally with sulph. ferri ointment; discharged in restored health on the 13th day.

The author of the paper contended for the general or zymotic character of diphtheria; and suggested that the results of treatment with the hyposulphite, as an agent capable of neutralizing the toxic principle in the disease, in the cases which he had detailed, afforded encouragement to further trial of that medicine.

A discussion ensued, in which Drs. Moore, H. Kennedy, Lyons, Hibbert (of the United States), Professor Haughton, and other gentlemen took part. At its conclusion,

Dr. T. MORE MADDEN read a paper on

INSANITY AND CRIMINAL RESPONSIBILITY.

A commentary on a remarkable case of attempted murder and suicide, committed under the influence of a disordered state of mind, in which the individual, who, to outward appearances, was sane, and was earning his living in a situation, suddenly attempted these crimes, and but

for the exertions of a medical gentleman, would have been tried and punished for them. A very remarkable document, in a psychological point of view, written immediately before this attempt, was afterwards found, in which he assigned his reasons for it. Dr. T. M. Madden read a portion of this very curious paper, containing the clearest proof of insanity. In the course of his observations on the case, Dr. T. M. Madden pointed out that if this individual had succeeded in this attempt, he would have been tried for murder, and very probably would have been hanged. He proposed that for legal purposes, insanity should be divided only into general and partial. He argued against the term, moral insanity, and proposed the recognition of what German psychologists term the state of "half freedom,"—a state intermediate between sanity and insanity. Dr. T. Madden then proceeded to explain the present condition of the English law in reference to so-called criminal insanity, quoting from the decisions of the judges and their charges to juries from 1720 to the present year, and contrasted with it the laws of other countries, with reference to insanity. The consequences of the laws that are still enforced in England are, that persons undoubtedly mad may be, and often have been, hanged for crimes committed in that state. Dr. Madden proceeded to illustrate this opinion by reference to various cases between 1812 and 1866, in which madmen were either sentenced to death or actually executed. From these cases he argued the necessity for a revision of the laws relating to insanity, and proposed that this might be simply and effectually accomplished by a short act providing that no lunatic should be dealt with or punished as a person of sane mind; and, secondly, that assessors in lunacy should be appointed, who in all cases in which the question of mental capacity arose, should advise the courts of law on all professional points.

The Rev. Professor HAUGHTON read a paper on the GEOMETRICAL FORMS ASSUMED BY GALL STONES, which he attributed to their mutual pressure.

From a measurement of seventy-two angles, he found them reducible to seven groups:—

I.	90° 28'	(18 angles.)
II.	70° 59'	(19 angles.)
III.	106° 21'	(7 angles.)
IV.	116° 26'	(7 angles.)
V.	59° 9'	(6 angles.)
VI.	99° 4'	(7 angles.)
VII.	80° 15'	(8 angles.)

Dr. Haughton referred the angles I. II. III. to the cube, tetrahedron, and octahedron inscribable in a sphere; and considered angles IV. V. reducible to the rhombic dodecahedron, or form of cell of the bee; the remaining angles VI. VII. he was unable to explain. The mathematically exact angles of the geometrical figures referred to are:—

1. Cube	90°
2. Tetrahedron	70° 31' 7
3. Octahedron	109° 28' 3
4. Rhombic dodecahedron	120°
5. Do. do.	60°

DEATH FROM EATING DISEASED MUTTON.—An inquest was held on Saturday, near Thirsk, on the body of Henry Stringer, aged four years. The child had been living with George Dale, a labourer. A few days ago Dale had a neck of mutton presented to him by a farmer, a portion of which was boiled by Dale's wife, and she and deceased, her own children, and others, partook of it; also of the broth. Soon after the party manifested dangerous symptoms, the little boy Stringer, particularly. It appeared that the mutton had been unsound. Medical assistance was called in, but the child died on Thursday last. The verdict of the jury was that death was caused by irritant poison, by eating animal food. Three of Dale's children were also taken ill, and they are not yet out of danger.

Foreign Medical Literature.

OF CLUB-FOOT: PERIOD OF OPERATION: TREATMENT

(SURGICAL AND MECHANICAL).

By M. GIRALDES.

Translated from *La Presse Médicale Belge* for THE MEDICAL PRESS AND CIRCULAR, by

Dr. JOSEPH DUGGAN,

EX-SENIOR SCHOLAR IN THERAPEUTICS AND PATHOLOGY, QUEEN'S COLLEGE, GALWAY.

YOU have seen this morning a fine collection of club-foot—five in the ward St. Côme, and two in the ward St. Pauline. The first are of the species of club-foot called varus, and did not differ from each other, except in some slight characteristics. These deformities are very common, so it is of the utmost importance that you should know what means ought to be adopted to remedy them. Physicians, for the most part, pay little attention to this branch of the science, leaving the invalids to themselves, and, thanks to this negligence, the deformity goes on increasing, and, save by surgical interference, the foot remains almost useless, at least very doubtful in its results. It happens then by reason of this incertitude, the unhappy individuals bear an infirmity which, in certain states of society, is for them a source of grief and *ennui*. Lord Byron was club-footed, and that deformity rendered his life unhappy; and also Walter Scott was similarly afflicted, but bore more buoyantly his inconveniences, and did not in the least bear any animosity to Nature. Finally, we add that the existence of such a malformation must seriously impede or fetter the choice of a career.

Before explaining the treatment, we go to examine—1st, in what the deformity consists; 2ndly, at what period it will be convenient to operate.

There are, you know, four species of club-foot, based upon the position which the movements impress to the foot. *a.* If there is exaggeration in the sense of flexion, the heel is directed downwards and rests alone on the ground. This is talus. *b.* When the foot is in forced extension, like that of digitigrades, the fatty cushions of the plantar surface of the toes alone resting on the ground, it is called equinus. The lateral deviations are:—*c.* Sometimes outwardly, the foot resting on its internal border—valgus. *d.* Sometimes inwardly, the foot resting on its external border—which is varus. Those four species of club-foot may be either very light or very well marked; and between the two extremes an indeterminate number of varieties may occur.

To-day I purpose speaking to you on the species of club-foot called varus. In this species the dorsal surface of the foot is turned outwardly; the external border beneath rests upon the ground, either in its whole extent or in part—a frequent phenomenon; the heel is elevated; the internal border of the foot describes a hyperbolic curve; the anterior part of the foot is of less dimensions than in the normal state—a character which points out the congeniality of the conformation. Here, among the infants in the ward St. Côme, the affected foot is shorter and squarer than the sound one. In these defective conditions all the movements operate in the medio-tarsal articulation, and around the two centres of rotation corresponding the one to the tibio-tarsal axis, the other partly to the articulation of the calcaneum with the cuboid, and partly with that of the astragalus with the scaphoid.

All the twisting is produced in the anterior part; the foot is rolled upon itself; its faces become almost perpendicular to the ground, upon which it rests only on the external border, and oftentimes the corresponding face, rarely the calcaneum. This abnormal position occasions the development of mucous bursa, chiefly where there is constant pressure; bursa, which are frequently the centres of in-

inflammations, fungosities, and even pale white tumours. I dwell specially on this point, because that the appliances put in use do not at all oppose but indifferently this twisting movement.

These defects of conformation, which have occupied us for some time, and the action of the muscles moving the foot in divers ways, gives place to a multiplicity of modifications, consequently it is useful to recall the order of ossification of the bones of the foot. The first which ossified is the calcaneum; the second, the astragalus; the third, the cuboid; the fourth and fifth, the cuneiforms; the sixth, the scaphoid. Towards the sixth month of intra-uterine life the points of ossification are visible, but the bones are still cartilaginous. If, then, muscular forces are brought to bear upon them, they will undergo changes of form and position.

In congenital varus, for example, the head of the astragalus will be turned towards the internal side, the anterior tuberosity of the calcaneum lengthened, also the cuboid; the metatarsals will be atrophied. It is a result from the deformities produced by modifications of the bones of the side of the foot, and then to the action of different muscles, principally the soleus and the tibials. The first draws the heel upwards. The anterior tibial (which is attached to the tubercle of the first cuneiform) and the posterior tibial, which is inserted into the base of the same cuneiform and to the tuberosity of the scaphoid, have in general, by identical actions and by their contraction, a tendency to carry the foot inwards. In consequence of the malformation which changed their direction, the muscular forces act perpendicularly, which renders their action more energetic, and increases the deformity. Also adding to this, the antagonistic muscles, partly atrophied, have not the power to oppose them. From these considerations two important indications are derived—1st, to subtract the forces which placed the foot in its abnormal position; 2nd, to correct those, in replacing the organs in their natural position.

What is the period most favourable for remedying the deformity?

The deformity is increased with age, and it is reasonable to conclude that it is necessary to cut short its development by attending to it as soon as possible; but at birth the organs which enter into the composition of the foot are very small, so the operations which the infirmity requires must be very difficult of execution. Those motives have induced many surgeons to postpone the time for operation to a later period. In this hospital they waited a year or two, and I am the first who had there inaugurated the treatment of club-foot, by operating immediately after birth. We have said that to combat these vices of conformation, it is necessary to destroy the antagonisms which aggravate and displace the organs from their natural position. Thence the section of the tendo-Achilles and of the tibial tendons, and the application of special apparatus. As a rule, we ought to commence by dividing the tibial tendons, the posterior first; that section produces the club-foot (equinus), which soon heals. You have seen me here very frequently commence by dividing the tendo-Achilles. It is then better to leave persistent the action of the tibial muscles; it permits remedying the deformity of the foot by lowering the heel.

On the other hand, the incision of the posterior tibial tendon is not entirely free from danger, on account of its intimate relation with the artery of the same name. Oftentimes the artery has been wounded, giving rise to the formation of a diffuse aneurism, &c.

If, however, after having cut the tendo-Achilles, the bandages or the apparatus are insufficient to counteract the deformity, we divide the tibial tendons. Even though the tendons are divided, it is necessary to place the parts in their true physiological position, for this we must have recourse to mechanical means; they vary with the age of the patients. If operating on new-born infants, complicated appliances are defective.

It would be much better to employ simple splints, more

or less bent, according to the proposed designs, wadded to prevent contusions, and consequently abrasions, which, in spite of all possible care, are oftentimes produced. That is, above all, when the splints do not descend just to the inferior part of the foot, but press on the middle part, that these accidents are to be feared. For the most part, the employment of that means is easy, for it does not require the aid of a skilled mechanic to make an apparatus so simple.

Furthermore, if the deviation has not completely disappeared, we must have recourse to the ordinary mechanical means, of which the number and form are varied to infinity. The notion of employing these mechanisms is not of modern date. Already Ambrose Paré made use of a kind of leather garter.* Arcius had invented an apparatus which very nearly resembles ours, and approaches nearly to the sandal of Scarpa.†

Most of our apparatuses are composed of two side pieces corresponding with the lateral faces of the leg, on which they are kept by the aid of a leg splint; below these are fastened to the sides of a sandal, fixed on the foot by buckles. They present two kinds of movements; one lateral, the other of flexion and extension, corresponding to the tibio-tarsal articulation—useless movements, since they do not pass exactly in the two centres of movement which we have pointed out. Moreover, those appliances are very cumbersome, and do not half fulfil that which we desire to obtain.

M. Lebellegue has invented an apparatus composed of many segments articulated together.

Of all those mechanisms, that which appears to me to satisfy most advantageously the required conditions, is evidently that of Mr. W. Adams.

In conclusion, with all those appliances, we tried, by the aid of leather straps, to draw the foot outwards, but often we hide the deformity without correcting it. Almost all are easily displaced and difficult to manage, requiring frequent visits from the orthopædist. So, to fill up the desiderata of the science, and to place those appliances within the reach of every person, some new instruments are yet indispensable. Orthopædic mechanists have need to be guided by the directions of surgeons in performing what alone is necessary, rather than fabricating machines only useful to place in a glass case to attract the public.

BOUMÉVILLE.

(Extrait du *Movement Médical*)

Turloughmore, county Galway.

* To replace varus or valgus club-feet in their normal position, Ambrose Paré recommends small boots, properly constructed, about the thickness of a coin, made of soft leather, and opening before and under the foot, in order that they can open better to admit the foot, and will be laced and fastened conveniently. (Ambrose Paré t. xi. Ed. Malgaigne.)

† In the apparatus of Scarpa, the point d'appui is a spring bent outwards, joined to a plate bent upon itself, which surrounds the ankle; the agents of redressment are two leather straps, one fixed upon the end of the foot and the other upon the heel; the ends are buckled to the external spring, which keeps the foot outwards. (Laugier, *Diet.* vol. xxx.)

RELIGIOUS ENTHUSIASM.—Incredible as it may appear, a body consisting of thirty Irish gentlemen have refused to receive a sum amounting to several thousand pounds for the support of a county infirmary. The case is this: the late Mr. J. Grattan thirteen years ago left a sum of £4500 to the Queen's County Infirmary, which sum has not since been applied. Mrs. Gratian Bellew, owner of the Grattan estates, now offers to pay up the money with arrears of interest, and to add £1000 of her own for the erection of an hospital or ward for convalescents and incurables of all religious denominations, upon condition that the hospital shall be placed under the care of the Sisters of Charity, with every safeguard against interference with the religion of the patients, and with free access to the clergy of all persuasions. The Governors of the Infirmary, thirty-one Protestants and three Catholics, met to consider this proposal, and it was negatived without a division.

ABSTRACT OF
METEOROLOGICAL AND MEDICAL OBSERVA-
TIONS TAKEN AT THE MILITARY
HOSPITAL, NICE,

FROM THE 10TH TO 20TH MARCH, 1866.

By Dr. CABROL,

CHIEF PHYSICIAN TO THE HOSPITAL.

Translated by R. CROTHERS, M.D., Nice.

In our last bulletin we remarked as surprising the amount of rain, more than (ten centimètres) four inches, fallen at Nice in a very few days; the same thing has again occurred, the rain having commenced anew on the 16th and continued almost without intermission, being very heavy on the night of the 18th. According to the indications furnished by the rain-gauge, this fall of rain also amounts to ten centimètres (four inches.) The ground being already saturated by the heavy rain in the early days of the month, the waters of the Paillon increased from the beginning and attained its maximum on the morning of the 19th; it has since gradually fallen, but remains muddy, and discolours the sea for a considerable distance towards the east. During these rains the barometric pressure has always been above 0.750 (29.5-10ths), but on the 14th it fell suddenly from 752 to 742 (from 29.7-10ths to 29.2-10ths). This considerable fall indicated atmospheric disturbance, and we expected to perceive the effects of it in Nice or its vicinity. However, the 14th was one of the finest days of the month; but in the evening there was a very high wind for some hours, the mistral having blown violently and raised clouds of dust; doubtless the effects of a distant tempest, as indicated by the sudden fall of the barometer. Moreover, these rapid changes have been the rule in these ten days, the barometer having varied from 0.765 to 0.742, then from 0.742 to 0.754, indicating weather exceedingly variable even for this season of the year. Except on the 14th, the wind has generally blown gently, most frequently from the S.E. in the early days, and from N.E., and even North; in the latter the sea has been rough, but not so much so as in the preceding decade.

The mean temperature has been 51, the lowest 34 on the night of the 13th; that which is most deserving of notice is the excessive amount of humidity (91) on the 19th, after the rain, and also the very considerable amount of ozone present in the air for some days, the test papers having several times shown the maximum of violet colour indicating the 21st degree of the scale of Janus.

To sum up. The ten days just passed may be divided into two periods—one, up to the 14th, was very fine; the other, marked by variable winds, clouds, and rain, continues even to the present: this coincides with what is observed elsewhere. We hear of cold, of heavy rains, of snow, even in the south; of hoar frosts and thick fogs in some places; whilst in part of Provence the cold has been so intense as to destroy the flowers. Vegetation here has not suffered; on the contrary, it has benefited by the rains, which have conferred the further advantage of increasing the subterranean reservoirs destined to supply our springs during the summer.

As to the influence of this weather upon health, there are few invalids who have not suffered more or less; but to this state of atmosphere, exempt from snow, from frost, and from fog, we cannot attribute any fresh outbreak of serious diseases; they are confined to those generally observed under the influence of a humid air and soil, such as returns of rheumatic pains, sore throats, asthmas, catarrhal and bronchial, also neuralgic affections, &c.

Medical practitioners may be permitted to assert that these simple irritations which have appeared during the last ten days would elsewhere have been serious diseases, and consequently, the longer we observe the climate of

Nice, the more convinced we are that it is, upon the whole, a country very favourable to invalids and persons suffering from chronic complaints.

ACUTE PROGRESSIVE PARALYSIS.

DR. PELLEGRINO LEVI describes a case which he observed in the wards of M. Pidoux, of acute progressive paralysis. The patient was a young man, aged 22, a notary's clerk, of strong constitution, and hitherto of excellent health. For two or three months he had a general feeling of weariness, with heaviness of the head, and remarkable drowsiness in the evening. Suddenly the weariness and debility made rapid progress, and in five or six days paralysis was developed. When Dr. Levi first saw him, he could not move the lower limbs, but retained some sensation in them. The application of the induced current produced a painful feeling and very active contraction. The patient did not suffer during sleep; but, when his position was changed, he complained of severe pain. He had tingling sensation in his toes; but there were no cramps, nor contractions, nor vibrations of the muscular fibres. The upper limbs were beginning to be attacked, and the muscles lying along the spine were paralysed; those of the neck and head were unaffected. His speech was slightly impeded: the intellect was sound; the respiration, circulation, and temperature, were normal. He had had obstinate constipation during several days. Micturition was easy; the urine was alkaline. In a week, the paralysis of the upper limbs became complete; and the diaphragm and other respiratory muscles were affected. There were oppression, dysphagia, constant sleeplessness, change of countenance; and the patient died asphyxiated, having preserved his intellectual faculties to the last moment. On post-mortem examination, there was merely found congestion of the meninges and of the grey substance of the brain, and of the lungs and kidneys; this could be sufficiently explained by the asphyxia. Not the slightest alteration could be detected by microscopic examination in the nervous system.

Dr. Levi records other nearly similar instances from the writings of Ollivier d'Angers, Cruveilhier, O. Landry, Kussmaul, Liégard, Duchenne, Pidoux, &c. The history of the disease and autopsy of the celebrated Cuvier presents a very close analogy with that of the patient whose case is above related. From a consideration of all the facts, Dr. Levi has traced a general view of the symptoms of the disease denominated by M. Landry acute ascending paralysis, and which he proposes to name centripetal or acute extensor-progressive paralysis. The case related shows the main characters of the disease. There is a premonitory period lasting from a few hours to several weeks, the characteristic symptoms of which are tingling of the toes and fingers, and weakness of the limbs, especially the legs. This weakness is transformed into paralysis, which attacks in rapid succession the limbs, the trunk, the diaphragm, and the pharynx, thus producing dysphagia, dyspnoea, and ultimately death by asphyxia. Sensibility is preserved in the paralysed muscles, which generally contract under electricity; reflex movement is lost; there is no spasm, contraction, muscular tremors, nor spontaneous pain. Speech is impeded; the intellectual faculties are preserved: the patient is anxious, and sleepless. There is obstinate constipation, while micturition is easy. Death occurs from the third to the twentieth day. In very rare cases, recovery takes place; but much more slowly than the progress of the disease—the muscles last attacked being the first to resume their functions.—*Archives Générales de Méd.*, and *Gazette Méd. de Paris*.

PAPULAR ERYTHEMATOUS ERUPTION FOLLOWING VACCINATION: CONVULSIONS AND DEATH.

ON November 6th, 1865, Dr. Coutagne vaccinated several children from a pustule on the arm of a healthy child. The vaccination went through its course normally in all, except in a female infant, aged three and a half months, apparently in good health and in the best possible sanitary condition. The pustules were at first developed regularly in this child; but, on the fifth day, there appeared an erythematous redness over great part of the body and the limbs, without marked febrile reaction. This erythema lasted five or six days, and then disappeared. On the twelfth or thirteenth

day after the vaccination, the pustules were desiccating, and the child appeared well. Dr. Coutagne had taken the precaution of confining it to the house, in order to avoid cold. On November 20th, the fourteenth day after vaccination, Dr. Coutagne was called to see the child, on the 10th of which several dark spots had appeared since the previous evening. He found on the neck, arms, and legs, a score of papular spots, some slightly acuminated, like small boils; others flattened like patches of urticaria, with an engorged base, occupying the entire thickness of the skin. In some parts, especially the anterior and upper parts of the thighs, two or three of the acuminated papules were grouped together on a common base. Most of the spots had a reddish brown colour, which was most marked on the largest and flattest—those on neck and lower part of the face. These projected slightly, were somewhat rugous on the surface, and resembled patches of urticaria that had been blackened by nitrate of silver. There had been no appreciable *malaise*, but the child had been restless during the night, had cried repeatedly, and had refused the breast several times, but was at length induced to take it. There was no fever; the abdomen was not tense, and did not seem painful. Some simple medicine, and injections, were prescribed. In the evening there was no sensible change. The next morning the child seemed a little better; the skin was not hot; but some conical papules had become developed in the feet, hands, and ears, and the colour of those already present had become deeper. In the afternoon fever and much agitation set in. In the evening the symptoms were aggravated: the child cried continually, and moved its limbs almost incessantly. The eruption was more developed; the number of papules was double of that which existed on the previous day. There were none on the chest, abdomen, or loins. At midnight the restlessness increased; convulsions soon set in, and one paroxysm followed another without cessation until the morning. Calomel, antispasmodics, cutaneous revulsion, and all tried without effect: the convulsions continued, and the child died on the morning of the third day of the eruption and the sixteenth after vaccination.

In commenting on this case, Dr. Coutagne observes that the occurrence of erythema in the course of vaccination is not rare; but that this does not explain the occurrence of the eruptive disease which proved fatal in the case related. It may have been, that there was a mere coincidence; and that the second eruption was altogether independent of the former. — *Gazette Médicale de Lyon*.

FATTY LIVER IN CHILDREN.

IN 222 children affected with adipose infiltration or with fatty degeneration of the liver, Drs. Steiner and Neureutter found that in 131 the age was from one to four years. Among the pathological conditions in the course of which fatty liver appears, the most frequent is tuberculosis; and the fact that this state in children is most frequently manifested as disease of the lymphatic glands and not of the lungs, negatives the supposition that the excessive deposit of fatty matter in the liver in connection with tuberculosis is due to deficient oxidation of hydrocarbons. Drs. Steiner and Neureutter consider rather—and in this they agree to some extent with Frerichs—that the origin of fatty liver is to be sought rather in the change in the constitution of the blood induced by the tuberculous disease, and that the liver may be fatty from the commencement of the tuberculous process. Next in order to tuberculosis in connexion with fatty liver, is enteritis; which is not, however, to be regarded always as a cause. It may be preceded by the fatty disease; or, in many cases, the two diseases are very probably due to a common cause. The exanthemata may also be followed by fatty liver; and the connection between these is only to be found in the changes of the blood. Fatty liver is also observed in connexion with diseases of the bones in children, such as tuberculous caries and rickets. It is an error to ascribe the condition of the liver to the use of cod-liver oil in such cases; inasmuch as it is met with in children who have never taken oil, in as advanced a state as in those who have used oil for a year. Cases also of bronchitis, pneumonia, pleuropneumonia, and heart disease, sometimes occur in which fatty deposit in the liver is met with. Of the causes indirectly affecting the liver, diet holds a principal place; inasmuch as the children have either a diet very rich in fat, or (especially among the poor) one deficient in fat but rich in hydrocarbons; and the mischievous in-

fluence of this diet is increased by the deficient metamorphoses resulting from want of exercise and from impure air. The authors draw a distinction between adipose infiltration and true fatty degeneration; and observes that the former condition appears to be more frequent in children than the latter, inasmuch as it was met with in 188 cases out of the 222 examined. They hence conclude, that in by far the greater number of cases, fatty liver is not to be regarded as a result of malnutrition of the hepatic cells, but as the result of causes acting from without.—*Jahrbuch der Kinderkrankheiten*.

CHANGES IN THE ADIPOSE CELLULAR TISSUE IN AMYLOID DEGENERATION.

THE adipose tissue, says M. Hayem, in cases of more or less complete amyloid degeneration, becomes firmer and harder than in the normal state, and has a whitish appearance. The small arteries visible to the naked eye are thickened, as in the other organs which have undergone degeneration. By the microscope, the amyloid matter is seen to be deposited in the cellular fibres of these arteries, and on the external surface or in the substance of the capillaries. In some rare instances, the adipose vesicles themselves are infiltrated with amyloid matter, which is apparently deposited in the substance of the envelope, around the nucleus, which remains visible. The fat contained in the vesicles, or the crystals of margarine are pushed to a point opposite the place of deposit of the amyloid matter, or even seem to be surrounded by it. At the same time, an increased number of nuclei are frequently found in the connective tissue. M. Hayem has observed the changes in the adipose vesicles generally in the abundant adipose tissue enveloping the kidneys and suprarenal capsules, in that lying on some of the folds of the mesentery, and in the fatty appendices of the epiploon. In such cases there was very advanced degeneration of several organs, especially of the kidneys and suprarenal capsules, and also of the digestive canal.—*Gazette Méd. de Paris*.

FIRE-DAMP.—Mr. G. F. Ansell exhibited in one of the committee-rooms of the House of Lords last week an apparatus of very simple construction, whereby a sudden outburst or gradual accumulation of gas in a mine would give almost immediate warning of its presence. The instrument exhibited was formed, in the first place, of a glass flask six inches in height and two in diameter. Its top was tightly covered by a piece of common red tile, and from its bottom went a narrow tube, which, being bent upwards, rose to double the height of the flask itself. Mercury was lying in the bottom of the flask, and, of course, to the same level in the tube also. In the upper part of the narrow tube were the projecting ends of two isolated wires, connected with a small galvanic battery. This forms the whole apparatus, and we may suppose that the flask is placed in a part of the mine where some men are at work, while the wires could be extended to the top of the pit, and there be connected with a battery and bell. If, while the men were working, a small or large quantity of gas were suddenly disturbed, some portion of it would percolate through the tile and gather in the flask with remarkable rapidity. There it would press the common air upon the mercury and induce it to rise in the narrow tube until it reached the wires. Immediately the mercury touched them the galvanic current would be complete, and the bell would be set ringing. This warning would be given in less than two seconds from the time the gas made its appearance. And another instrument, designed upon the same principle, would give warning of a gradual accumulation of gas when it had become dangerous. Mr. Ansell also shows an instrument a little larger than a watch, and constituted upon the principle of the common barometer, which the mine viewer could take in his hand; and if in the course of his passage through the mine he came upon any place where the atmosphere was charged with even one per cent. of gas, the instrument would register it.

THE DEMAND FOR GARLIC.—If Mr. Worms has been of little use as a curer of rinderpest, he has, nevertheless, done the garlic-merchants of Covent Garden a useful turn. We are informed that—thanks to his specific cure—there has been such a run on the garlic market, as to send up the price of that article from 3d. to 2s. per pound.

ST. PANCRAS WORKHOUSE.

AN inquest was held last week upon the child who was "laid out" before its death, and the following, among other evidence, was adduced:—The Coroner recalled Dr. Ringer, the physician of the University College Hospital, who made the post-mortem, and asked him if he considered the treatment the child had received had caused its death. Dr. Ringer replied that the child was in such a wretched condition that its death was inevitable, but he thought it unquestionable that the bandaging the child up as described must have accelerated its death. At the suggestion of Mr. Ernest Hart, who was present to watch the case in the public interest, the Coroner asked if a child or any patient in witness's hospital would be left without being seen by the medical officer from Monday to Thursday, to which the witness replied in the negative, saying that every patient would be seen every day, and the Coroner emphatically added that in no hospital in the country would a patient be open to such treatment as this child received in the workhouse. Dr. Ringer then added that he believed the child had all the attention the medical officer of the workhouse could give it, for an hospital doctor did not have a tithe of the patients to attend to that the medical officer of St. Pancras Workhouse had. Some of the jury expressed their doubts of this, and Mr. Butt, the medical officer, offered himself for examination. He said he was a duly qualified M.R.C.S., and that having visited the nursery on Monday, he did not find it necessary to go in again until the following Saturday, as he relied upon the superintendent telling him if any of the inmates required his attention, and she told him all were going on well. In reply to questions put by Mr. Hart, through the Coroner, important facts were elicited. The witness said there were at the present time 240 sick persons in the infirmary; 430 aged and infirm women, 212 infirm and aged men, 42 insane men, and 90 insane women, making a total of 1014 persons in the doctor's hands, in addition to 32 lying-in cases, which made a total of 1042 under the medical officer's immediate care, and his only staff was another qualified practitioner. There were, in all, it was elicited, about 2000 persons in the workhouse, and, in addition to those under the doctor's immediate care, there were sure to be other cases. Dr. Ringer said a medical officer of an hospital would have no more than 60 or 70 cases under him at one time. The jury, on hearing this statement, said it was most important the public should know these facts, and some remarks were made to the effect that the Poor-law Board should not sanction such a state of things. Mr. Hart informed the Court that the Poor-law Board had no power in the matter, which a guardian present confirmed by saying, "We don't ask the Poor-law Board to sanction what we do." The Coroner said a medical officer could not be expected to attend to so many cases, and he could not be expected to see the child as it ought to be seen—every day. Mr. Butt said he might add, that he did see the ward three times in the course of a week. He saw the ward on Monday, Saturday, and Sunday. Mrs. Sanson, the superintendent, was examined, and she gave the evidence already published—namely, that she did not call the doctor. In cross-examination she said she thought the rule to call the doctor to a dying person or child was generally carried out. She candidly confessed that she was over-worked, as were all the officers, and her case was a sample, she having 156 people to look after, and not a single paid nurse under her. The jury returned a verdict to the effect that the child died of inanition, and appended the following special resolutions:—"The jury are of opinion that great blame is to be attributed to the workhouse attendants for tying up the jaws of the deceased and treating her as dead for some time before she had wholly expired; that they are further of opinion that there is not a sufficient number of paid medical attendants and nurses to perform the duties of so large an establishment as St. Pancras Workhouse; and they beg to express their approval of the course taken by Mr. Hillocks in bringing the matter before the public."

Reviews.

ATLAS OF PORTRAITS OF DISEASES OF THE SKIN. Edited by the New Sydenham Society. Fifth Fasciculus.

THE fame of this Atlas—so far as it has gone—is now so well an established fact, that our readers will not require us to give any opinion thereon, or to show any reasons why this publication should not be regarded as one of the best results of the New Sydenham Society.

Already eleven portraits have appeared; and we are now called on to say a few words regarding the twelfth, thirteenth, and fourteenth, which form the Fifth Fasciculus of this remarkable work.

Plate XII—Pityriasis Versicolor—is, like all the rest, well coloured, and represents a fully-developed typical case of that disease in an adult male. It is particularly well shown over the abdominal muscles and on the biceps of each arm.

Plate XIII—Pemphigus—represents that disease fully developed in a child; the parts affected being—the face from the nose downwards, the neck, shoulders, chest, and the upper third of the left arm.

Plate XIV—Psoriasis Vulgaris vel Inveterata—is perhaps the best of the three. It represents that disease in three different stages, and the scales are remarkably well executed.

These plates fully support the reputation acquired by the merits of the preceding ones; and we look forward with pleasure to seeing a further issue of this series. Meanwhile we congratulate the editors and the artists on the success of their labours.

SYMPTOMS AND TREATMENT OF THE CATTLE PLAGUE, WITH A SKETCH OF ITS HISTORY AND PROGRESS. By ARTHUR WYNNE FOOT, M.D. Dub., &c., &c. Dublin: MacGlashan and Gill. 1866.

Dr. Foot is well known to the profession as a good anatomist and an accurate observer. He was one of three medical gentlemen recently sent from Dublin to England by the Irish government, for the purpose of studying the Cattle Plague; and we are glad to see that he *has* studied it.

Chapter I. is devoted to discussing the symptoms of the plague during life; and here the author very properly observes "that all the symptoms are not necessarily present in every case. There are some more constantly met with than others, and there are some which are rather rare and exceptional. A beast may die of the plague, although during the course of its illness it did not present what is, perhaps, one of the most usual symptoms in the generality of cases; for instance, purging may be absent in an animal which, in other respects, presents all the appearances during life and after death which are characteristic of the disease." The *early* symptoms are clearly pointed out, especially that state in the beast which in some degree answers to our "malaise." The muco-purulent discharge from the eyes, and the pathological appearances of the mucous membrane generally, are pointed out with care; as are the condition of the bowels, the state of the breathing, the effusion of air under the skin, the skin eruption, the incubation and duration of the disease, its symptoms in sheep and goats, and the circumstances under which it becomes more or less modified.

Chapter II., on "Appearances after Death," is very important. We have here described, in terms which any well educated man can understand, the general appearances, the appearances in the four stomachs, in the intestinal canal, in the lungs, heart, blood, mouth, muscular system, and skin eruption.

Chapter III. deals with "Treatment and Preventive Measures." Here Dr. Foot says, with sad truth, "the prospect is gloomy in the extreme." Notwithstanding all this, how-

ever, we have given in a small compass the means used in Russia, Poland, Austria, Prussia, and Scotland, as well as the means, political and medical, adopted during the similar visitations of the 18th century. The hygienic precautions recommended for adoption by the farmer as anticipatory to, or in the event of, another attack, are peculiarly worthy of perusal by the class for which they are intended; and we have much pleasure in giving them our most earnest commendation. Of course among these the questions of inoculation and vaccination are duly discussed.

Chapter IV. to the student of medical history, is perhaps the most interesting, as it treats of the "History of the Disease," from which now, as a century ago, Ireland has been very remarkably exempted.

Dr. Foot is of opinion that the plague is "a specific disease, belonging to the class of contagious fevers." He knows of no remedy for it, and concludes his book with these words: "However mortifying it may be to the scientific mind of the present day, the fact is yet unpleasantly true, and may certainly now be received as established, that, as a general rule, treatment of any kind is worse than useless; and should the cattle plague reach this country, and the instant and unceremonious slaughter of all infected beasts be not effectively carried out, it is difficult to see how such a visitation can result otherwise than in the extermination of the horned stock, and in the agricultural ruin of Ireland."

The absence of a table of contents, and of an index, is a want which doubtless Dr. Foot will supply in his second edition; for we have no fear of its nonappearance. No country gentleman or intelligent farmer should want this book at the present time. We commend it strongly to these classes, as well as to medical men, magistrates, and police officers.

ON WAKEFULNESS. WITH AN INTRODUCTORY CHAPTER ON THE PHYSIOLOGY OF SLEEP. By WM. A. HAMMOND, M.D., Fellow of the College of Physicians of Philadelphia, &c. Pp. 93. Philadelphia: Lippincott & Co. 1866.

THE substance of this monograph has already appeared in an essay on Sleep and Insomnia, published in the *New York Medical Journal* last year. Dr. Hammond is so well known as an accomplished physiologist as well as a practical physician, that any contribution coming from his pen deserves the most thoughtful attention; and the subject he has chosen in this small volume is quite of sufficient importance to bring before the notice of the profession. The cause of sleep, according to Dr. Hammond, is the circulation of a less quantity of blood through the cerebral tissues than in the waking state—an opinion which is not held by most medical and physiological writers. But Dr. Hammond not only adduces the opinions of some authorities who agree with him in his views, but he relates some experiments performed by him on the lower animals, and which show that the immediate cause of sleep is a diminution of the quantity of blood circulating in the vessels of the brain, and that the exciting cause is the necessity which exists that the loss of substance the brain has undergone, during its state of greatest activity, should be restored. On this view it is shown why the recumbent position, in cases of insomnia, is less favourable to sleep than the sitting, because the former causes congestion of the brain; and the tendency to sleep after meals is explained by the diminished supply of blood to the brain owing to the increased activity of the circulation in the stomach. The treatment of wakefulness must be guided by the application of the above principles; and among the few drugs which Dr. Hammond recommends, bromide of potassium holds the most important place. Although the opinions offered as to the causes of sleep and wakefulness may appear somewhat paradoxical to some readers, they are argued out with great ability by Dr.

Hammond, and fully deserve to be put to the test of further experiment and observation.

PROSTITUTION MEDICALLY CONSIDERED, WITH SOME OF ITS SOCIAL ASPECTS. By Dr. DRYSDALE. Pp. 41. London: Hardwicke. 1866.

IS THE PLEASURE WORTH THE PENALTY? A COMMON-SENSE VIEW OF THE LEADING VICE OF THE AGE. By HENRY BUTTER. Pp. 16. London: Caudwell.

THESE two pamphlets refer to the same subject; but the authors respectively view it in very different lights. Dr. Drysdale regards it in a philosophical and medical spirit, showing by the evidence of facts that the health of the prostitute is not so bad, nor her moral condition so low, as many persons maintain; and that although she is undoubtedly subject to syphilitic diseases, yet she escapes many other affections to which females are liable. Among the causes of prostitution one of the chief is poverty, the low wages received by many women making them prefer that kind of life to other less lucrative but more laborious occupations. Dr. Drysdale then shows that the fearful effects of syphilitic diseases in the male subject are very considerably obviated in those countries where prostitution is placed under state supervision; and without recommending the adoption of the restrictive system prevalent on the Continent, he thinks that greater efforts ought to be made in this country to cure or prevent the diseases caused by prostitution.

Mr. Butter's pamphlet discusses the question in a totally different sense; and he points out the moral and physical degradation of prostitutes as well as of those who encourage them, as an argument for early marriages. He draws a fearful picture of the evils entailed by prostitution, not only upon the parties themselves but upon their posterity; and he argues that marriage, although it may be accompanied with trials and struggles, especially to the young who enter into this tie, is the only remedy for the great vice of the age.

THE BATAVIAN SOCIETY.

THE prize List of the Batavian Society for Experimental Philosophy at Rotterdam, contains, as usual, subjects peculiar to the Netherlands:—the management of polders; water-raising machines; an apparatus for measuring the rate of a river current; the movement of silt, and plans for irrigation. Among the purely scientific questions is an elaborate one on crystallography; the effect of pressure on electrolysis and whether boilers burst by a development of hydrogen gas, or by transition of the water to the spheroidal state? Others are: an examination whether some parts of the sun's surface have a higher temperature than others, or not; and in case of an affirmative, whether it is always the same parts? It is important for those occupied with the study of electricity to acquaint themselves with the principal phenomena produced in telegraphic wires by storms or the aurora borealis: many of these phenomena are known but to a few individuals although it is much to be desired that they might be widely published and their consequences deduced: the Society therefore, asks for an historico-critical notice of the principal observations made with reference to currents produced in telegraphic wires by the aurora or by storms. Another question refers to researches made in the Royal Institution:—Dr. Tyndall believes he can deduce with certainty, from his experiments, that the vapour of water exerts on radiant heat an absorbing effect much more powerful than dry atmospheric air. Prof. Magnus, on the contrary, feels himself justified in concluding from his experiments that this difference of absorption does not exist. The Society, therefore, asks for decisive experiments to settle the argument. The following will perhaps interest spectroscopists:—It has been proved recently that certain bodies, under different temperatures, produce different spectra. Are there yet other differences in the molecular state, which occasion different spectra of the same body? Required, an examination of this question, particularly with reference to the magnetic state. The answers to the questions, which may be written in Dutch,

French, English, German, or Latin, are to be sent to the Secretary of the Society before the 1st of February, 1867. The prize is a gold medal of the weight of thirty ducats, or the value in money.

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 4, 1866.

THE AMENDMENT OF THE MEDICAL ACT.

THE Profession will be rejoiced to learn that there is at length some probability that the present most defective Act, relating to the practice of Medicine and Surgery, will be amended. It has been stated, and we believe correctly, that Sir GEORGE GREY has prepared a measure with this object, and Dr. BURROWS, the President of the Medical Council, has been put in communication with the Counsel of the Home Secretary's Office, in reference to drafting an amended Medical Bill.

Every Member of the Medical Profession is so thoroughly well aware of the short comings of the existing Act, and such universal dissatisfaction has been expressed in reference to its operation, that it is almost needless for us to do more than to announce the intelligence that an amended measure is in contemplation; and it is only our duty to acknowledge the indefatigable exertions of Dr. BURROWS, which have chiefly led to this desirable result. The President of the Council is known to have exhibited the greatest energy and perseverance in inducing the Home Secretary to move in the matter, and the greater merit is due to the former gentleman, from the magnitude of the obstacles he must have had to surmount.

The very preamble of the Act, as it now exists, is a delusion, for it states that the object of the measure is to enable persons requiring Medical aid to distinguish qualified from unqualified practitioners; and this object the Act certainly does not accomplish, for quackery and illegal practice are as rife as ever; and, by a strange anomaly, those who are without the pale of the operations of the Act are better protected than those who are within it. The only protection which the Act really affords, is the publication of a Register, which the public neither buys nor reads, and which is therefore utterly worthless in attaining the end for which it professes to be printed. Any impudent pretender may set himself up as a Medical practitioner, and hundreds are doing so every year, and as long as they do not pretend to be on the Register, the law cannot meddle with their proceedings; and even in the most flagrant cases of assumption of Medical titles, experience has shown that the present powers of the law are entirely nugatory.

The amended measure will, therefore, begin by setting out that "the Medical Act has been found ineffectual to enable persons requiring medical aid to ascertain who are qualified practitioners;" and as every medical man

will at once perceive, the chief object of the amended Act will be to abolish the present obnoxious XLth clause. Although this clause is probably well known to all, yet it is necessary to reprint it, in order to exhibit the contrast between it and the amended clause agreed upon and recommended by the Medical Council. The clause, as it at present stands, is as follows:—

"Any person who shall wilfully and falsely pretend to be or take or use the name or title of a Physician, Doctor of Medicine, Licentiate in Medicine and Surgery, Bachelor of Medicine, Surgeon, General Practitioner, or Apothecary, or any name, title, addition, or description implying that he is registered under this Act, or that he is recognised by law as a Physician, or Surgeon, or Licentiate in Medicine and Surgery, or a Practitioner in Medicine, or an Apothecary, shall, upon a summary conviction for any such offence, pay a sum not exceeding £20."

The amended clause is as follows:—

"Any person practising Medicine or Surgery, or being engaged in the treatment of diseases or injuries, not being registered under this Act, who shall take or make use of any of the titles or designations enumerated in Schedule A to this Act, or that of Physician, Surgeon, Doctor, Professor of Medicine, Professor of Surgery, or any other title, name, or designation used by or used to distinguish duly-qualified Practitioners in Medicine or Surgery, shall, upon a summary conviction, be liable to a penalty not exceeding twenty pounds for each offence."

We need scarcely point out to all Medical practitioners in the United Kingdom, the urgent necessity of strengthening the hands of the Medical Council in every possible manner, with a view to carrying this amendment, and no time should be lost, especially at the present period when there is a brief recess from Parliamentary sittings, in impressing upon members of both Houses of Parliament the urgent necessity, in the interests of the public as well as of the Profession, of passing the amended measure. Recent experience has too abundantly shown how people, in all classes of life, are robbed, cheated, and we might almost say slaughtered, by persons pretending to the possession of Medical knowledge, and all this happens from the want of that very protection which the Medical Act professes to afford.

It may possibly be thought that the success of the amended Act is somewhat jeopardized by the uncertain tenure of office of the present Ministry; but this consideration, whether well or ill founded, ought to have no weight with the Profession, nor ought it to discourage any one from using the most strenuous exertions with members of Parliament, because the Medical Act is not at all a party measure, and whatever ministers may happen to be in office, the claims we possess are equally strong, and the objects for which we strive are identified with the interests of the whole community.

METHYLATED SPIRIT.—Dr. Lankester lately held an inquest on the body of a man whose death was caused by excessive drinking of a mixture of spirit of wine five and a half per cent. over proof, and of wood naphtha, which, as a medical assistant, he was in the habit of purchasing at the cheap rate of three halfpence for three quarters; in addition to which he took large quantities of opium. A verdict was returned in accordance with the medical evidence, of pulmonary apoplexy and effusion of serum on the brain.

THE NECESSITY OF AMENDING OUR SANITARY LAWS.

THE battle between local Government and centralization in sanitary matters may be now said to have fairly begun, and the victory already appears likely to be achieved by the latter. The local authorities, indeed, have so long had their own way that it is no easy matter to convince them that they are incompetent to the tasks they have undertaken, and in the fulness of their arrogance they find a difficulty in understanding how their proceedings should meet with the censure of the general public. The gross ignorance of many local Guardians, or Trustees, or whatever other name may be used to designate the Bumbledom which has so long mismanaged our sanitary affairs, has for many years brought down the contempt of all scientific and humane men; but it has always, until very lately, found support with the multitude, who care for little except the diminution of the rates, and so long as this object is accomplished, the welfare of the poor or the health of the community are matters which weigh as dust in the balance.

The laws of health are now gradually becoming understood, and experience teaches us that they cannot be violated with impunity; but, nevertheless, it must be admitted that their interpretation often requires the application of science, and that some of the operations of nature in the production and the removal of disease are difficult of explanation. It is, therefore, the more necessary for local boards to avail themselves of the services of men who have made it their special duty to investigate the physical sciences in their bearings upon public health, and to extend to such men their cheerful co-operation and their consistent support. If gentlemen elected as Medical Officers of Health are not competent to perform their duties, they ought of course to be removed, and their place supplied by others; but in the collisions which we have known to arise between these officers and the local Boards we find that the instances of disagreement are precisely in cases where the Medical Officers have been the most honourable, the most scientific, and the most conscientious.

In condemning, as we do most emphatically, the mismanagement displayed by most of the local boards, we have no desire to comprehend in one indiscriminate censure all the individuals who compose those assemblies. On the contrary, we know that many of them are highly honourable and accomplished men, but in general they bear but a small proportion to the noisy and ignorant demagogues around them, to whom the management of affairs is too often virtually intrusted; and it is very probable that in many instances, where flagrant jobs have been perpetrated or gross injustice committed by their colleagues, the respectable minority have protested, but in vain, against the course pursued.

The whole subject of our system of sanitary legislation has lately been taken up by the Metropolitan

Counties Branch of the British Medical Association, and is still under discussion by that body. An attempt is being made to obtain the co-operation of the other Branches of the Association with a view to impress upon the public, the Government, and the Legislature the recognition of a few leading points which are considered to be of the highest importance. Among these points it is proposed that a speedy and inexpensive appeal should be provided from the decisions of local authorities, that the appointment of Medical Officers of Health and of Inspectors of Nuisances should be made compulsory, instead of permissive, as it is at present in the provinces, and that the appointment and dismissal of Medical Officers of Health should be subject to the approval of some central authority. With a view of improving the sanitary condition of unhealthy localities, it is proposed to make it compulsory to remove persons labouring under contagious diseases into local refuges; and it is urged that the *early* removal of such persons should also be compulsory on unions and parishes.

In the above propositions, which we have sketched in bare outline, there is nothing unreasonable, and they contain the germs of much improvement in the sanitary condition of our country. They must commend themselves to the approval of all intelligent persons; and however much they may be opposed by local interests, we do not despair, in the present tone of public feeling, of seeing them adopted.

ON NURSING THE SICK.

In one of our more recent numbers we called the attention of the profession to the practical turn things are taking in some respects in Ireland, as evidenced by the movement set on foot of late with regard to Imbeciles and Idiots. An announcement in our penultimate number further called the attention of the profession to a much required improvement in a very vital part of the routine of everyday life—the nursing of the sick—by informing our readers that a lady of known benevolence and influence had interested herself in the matter; and that in one of the Dublin Hospitals—that founded by Dr. STEEVENS---we may shortly expect to find a revolution in the time-honoured system to which Ireland has, for the most part, been long accustomed.

It needs no argument in the columns of this journal to prove what we all admit---that to the nurse in the sick chamber are largely confided the issues of life and death; that in some of our most grave diseases she, in fact, holds the balance, so far as any human power can do so; and yet, while we all stand up for reform in Medical education and professional status, how little have we done to secure in one large and influential class of the community a constant and unfailing supply of educated and faithful nurses, such as may be readily found in London and in many other parts of England?

In Ireland there is a great deal of what our trans-Atlantic cousins call "tall talk" on every conceivable subject, and especially on religious matters, with which

we at once admit the efficient nursing of the sick is intimately connected.

In Dublin, at any rate, and in other large Irish towns, we believe, the Roman Catholic portion of the community have an organization ready to hand in the shape of conventual orders and sisterhoods. These are turned to account in caring for the sick, especially in Dublin; and, from our own experience of the result, we say advisedly the benefit of organization and method is great, as compared with the separate and convulsive efforts of individuals, however gifted and influential.

How these sisterhoods work is so widely known, and so fully appreciated by those who have profited by their honourable and gratuitous services, that we need not enlarge on them here. We are not identified in religious persuasion with the ladies who nurse the sick in St Vincent's, in the Mater Misericordiae, and in Jervis-street Hospitals; but we cannot withhold our admiration of that unrequited toil and of that true charity which exhibits itself—not in discussing abstract doctrines or knotty theological questions, however useful these may be, and often are in their proper places; but—in the well-known words of Dr. WATSON, the Chrysostom of our profession—in dispensing its peculiar benefits, “without stint or scruple, to men of every country and party, and rank, and religion, and to men of no religion at all.” There is, in our opinion, little to be desired in this direction as to the mode in which the work is done. We only wish the extent of it were greater; and we greatly regret that the services of these benevolent ladies could not be made available in the hospitals just named for the care of those affected with fevers.

This large class of diseases urgently requires good trained nursing; and why it should not receive it does not clearly appear, save in the case of Jervis street Hospital, in the charter of which a special provision exists for excluding patients affected with fever from its wards.

As to the others, some have very incorrectly, but perhaps not unnaturally, drawn the conclusion that all this taste for nursing on the part of amateurs, or of the “religious,” was a mere sentiment, which was found practically useless when put to the test of attending on cases of contagious or infectious disease. But the immediate object of these remarks is to suggest to the minds of a large class of our readers the importance of inaugurating in Ireland a well advised system for training nurses, and the means of carrying out such a system among the class most plainly requiring it—Irish “Protestants of all denominations.”

We have already stated our conviction that good nursing of the sick is intimately connected with religious principle; and this, to some extent, explains how it is that Ireland is behind the sister country in the matter now under consideration.

We confess that our co-religionists—for we do not now write of our Roman Catholic fellow-countrymen—are second to none in individual efforts, in doctrinal discus-

sions, and every thing else of that sort; but what we want, and urgently want, is the establishment of “Protestant” nursing sisterhoods, which have this grand advantage over unorganized work and spasmodic effort—that they tend to merge all personal action and avoid individual prominence, while the actuating principle is a sense of duty, not a hope of praise. To many the very name of a “Sisterhood” is fraught with horror, and is suggestive of mistrust. To such we would say that a Nursing Sisterhood is not necessarily founded on any objectionable model; that several and varying plans may be well tried side by side, and that, provided the work be done and well done, men of different religious views may fairly please themselves as to the mode of doing it. We have no sympathy whatever with that large and unreasoning class who talk of their “opinions,” and “views,” and “doctrines,” and at the same time not only do no good work themselves, but look with ill-concealed suspicion on those who do.

Their “opinions,” and “views,” and “doctrines,” are not only not entitled to any consideration, but they should create in the mind of every Christian man a spirit of rational inquiry as to whether theories leading to no practical results are not only worthless, but false.

In England at this time there are at least twenty-six Anglican Nursing Sisterhoods more or less after the Kaiserwörth type. In some of these, as at King's College Hospital, the nurses belong to a religious order, and are under their own spiritual heads, the hospital in which they serve being administered by a separate and secular governing body. In others the nurses are of a religious order; and their head administers the hospital to which they belong. In others, again, the institution is quite secular; while in a few the Society is religious, but composed of persons of different persuasions.

We are quite sure that all these systems could be fairly tried here, not only in our hospitals but in supplying district or parochial nurses for the sick poor, and special nurses for the sick in private houses.

The name of Miss NIGHTINGALE is so identified with the reformation which we now advocate; that it is sufficient to attract attention to the project even among those most prejudiced against “suspicious innovations.” A well known Irishman, the late eminent Dr. TODD, of London, had much to do with this matter, as regards King's College Hospital, where he had the influential support of the present Archbishop of DUBLIN, then Dean of WESTMINSTER, and Professor of Divinity in King's College.

It is fortunate that we have a man of his Grace's experience resident among us, as we should, doubtless, obtain the support of his influence and position for any well-advised measure, having for its object the improvement of nursing the sick.

We have now said sufficient to suggest to our readers the due consideration to which this important subject is entitled, and we shall be glad to receive any practical suggestions in favour of it.

Provincial Intelligence.

BIRMINGHAM.

BIRMINGHAM, MARCH, 1866.

ONE of the most laudable movements lately initiated in this town, is that for the erection of a Sanatorium for the reception of convalescent patients from all the hospitals. The scheme originated with some members of the local committee of the Cotton Relief Fund. Birmingham subscribed generously in aid of the distressed operatives of the north during the cotton famine, and raised some £15,000 for their aid; of this sum there remains a large surplus untouched, and applicable with the consent of the donors to any charitable object. A convalescent institution has been proposed, and has met with the warmest support. On the first mention of the proposal, Mr. Muntz promised a donation of £1000, to be increased to £2000 provided that the subscriptions handed over from the Cotton Fund surplus reached £4000. Miss Ryland offered the land for the site of the Institution, or, in the event of another locality being selected, the sum of £2000. With such a beginning success could not be far distant, and of the £12,000 required for the accomplishment of the plan, some £8000 have already been obtained. The benefits likely to accrue to the poor of Birmingham from the erection of such an asylum can scarcely be overrated, and the assistance that will be given to the hospitals will of necessity be great.

Every medical man in the habit of visiting the wards of a large hospital must feel that many of the inmates would be restored to health, not only much more quickly but also much more perfectly, if the pure fresh breezes of our country districts could be called in to aid the work of the physician. The scrofulous subject, admitted with an acute disease, would no longer, from the want of a comfortable home, remain in the wards of our hospitals till the fatal seeds of pulmonary mischief have too certainly been developed, but transferred to the Sanatorium would, in the enjoyment of the health-giving air, regain vigour for many a long day's work. An institution of this kind on a small scale has been supported by the generous aid of Miss Ryland for about two years past, and has afforded to the General Hospital a means of bestowing invaluable treatment to many of its convalescent inmates. A refuge of the same nature, to which the inmates of all the infirmaries, and even the patients of private practitioners, might be admitted, would render an immense service to the suffering poor, and enable the hospitals to dispense their aid to a greater number with greater efficiency. We may here allude to another proposition of almost equal importance, which will be submitted to the Poor-law Guardians at an early meeting. It has been suggested from time to time that the work of the Parish Medical Officers would be rendered much more effective by relieving them of the necessity of dispensing their own medicines to their patients. According to the present plan each district officer is required to provide drugs for the pauper patients of his district. This is found, and in our opinion will ever be found, a very unsatisfactory arrangement; it is therefore proposed that a Parish Dispensary be organised, in which all the prescriptions of the Parish Medical Officers should be compounded. It is to be hoped that this plan will be carried into effect, for we conceive it to contain elements of no small advantage to the poor. To

mention no others, it will certainly enable the Medical Officers to devote much more time and attention to the medical examination of their patients, and will exempt them from a troublesome portion of their onerous and ill-requited duties. At both the Hospitals Dr. Richardson's method of producing local anæsthesia has been frequently applied. Mr. Wilders was the first to introduce it here, and at the Queen's Hospital he has used it in several minor operations with the most satisfactory results. On Wednesday last Mr. Gamgee removed a fatty tumour of considerable size from a man's shoulder, local anæsthesia being produced by Mr. Wilders; the operation was painless, and produced the most favourable impression of Dr. Richardson's important discovery. In the extraction of teeth the process has been found to answer extremely well, complete insensibility having been in all cases obtained. The opinion here is that in all minor operations at least, the danger of chloroform can henceforth be avoided by the use of this highly efficacious invention.

I may here cite a case which was received lately at the General Hospital, as illustrative of the severe injuries from which, occasionally, good recoveries are made. A man was admitted with an abdominal wound of some inches in length, produced by a stab; through the abdominal walls protruded about three feet of strangulated intestine. The gut could not be returned through the aperture, the wound was enlarged and the intestines returned to the abdominal cavity. Strange to say, the man has made a perfect recovery, not a single bad symptom making its appearance throughout the case.

The meetings of the Midland Medical Society have, during the past month, been supplied with very interesting papers. Dr. Russell contributed an able essay on "Syphilitic Affections of the Nervous Centres," and pointed out at some length the means by which they were to be distinguished from the other diseases of these organs. He dwelt on the anomalous symptoms presented in these specific cases, as affording in most instances a clue to their diagnosis and treatment. Dr. Earle read a paper on "The Induction of Premature Labour," and laid before the members a careful *resumé* of the various modes adopted to this end. The author stated that, in the greater number of cases the operation was required for a moderate contraction of the pelvic brim, and that in such the eighth month was, in his opinion, sufficiently early for its performance. At the last meeting, Mr. Gamgee discussed the treatment of "Stricture of the Urethra," and gave a historical sketch of the many methods which have been advanced for the treatment of this affection. Mr. Holt's immediate treatment was frequently referred to in the discussion, and was especially advocated by the President (Mr. Furneaux Jordan). Several very interesting pathological specimens were also exhibited by Dr. Steel—viz., two specimens of encephaloid cancer of the breast, removed in the General Hospital, and also a recurrent fibroid tumour of a large size, removed from the neck. The spinal column of a patient who died from fracture of the sixth and seventh cervical vertebrae, was also shown by Dr. Steel. The man lived some twenty hours after admission, the breathing was diaphragmatic, and there was complete paralysis of the lower, but only partial paralysis of the upper extremities.

PROFESSOR HANDCOCK will commence his course of lectures at the Royal College of Surgeons about June next.

MEDICAL FEES IN SCOTLAND.

THE subject of professional charges has again been brought before the public in connexion with a case which came before the Sheriff Court at Falkirk a few days ago. Dr. Cuthill, of Denny, brought an action against the trustees of the late Michael Benny, Esq., of Ingievar, for the recovery of professional fees for attendance on the deceased, and the Sheriff-substitute found for the pursuer with expenses. Against this decision the trustees appealed, and the defence set up was that the charge of five shillings a visit was much too high, and unwarranted by the customary charges of other medical men in the district. The pursuer, in support of his claim, adduced a number of medical men practising in his neighbourhood, who gave evidence to the effect that they considered the charges made were reasonable and fair. Moreover, the late Mr. Benny was notoriously wealthy, and in the receipt of an income of £3000 a year. Last week Sheriff Moir dismissed the appeal, and in a note expressed regret that such a trifling matter should have formed the subject of litigation.

Now in this case, and in many similar cases, the want of an authoritative scale of charges which might be referred to, was much felt, and it would be a wise thing for the medical men in every district in Scotland to draw up some regulations on the subject. In Edinburgh the want of a proper table of fees is greatly to be regretted, and we venture to say that in no other city in the three Kingdoms is there more dissatisfaction amongst the public regarding the way in which the medical practitioners render their accounts. The practice which prevails here of sending in a note of the number of visits without stating the charge, is undoubtedly most absurd, and there is, we know, a growing dislike to it on the part of the patients. Why should not doctors manage the business part of their profession on business principles? There would surely be nothing *infra dig.* in that! And why should the Edinburgh practitioners deem it unworthy of the dignity of the profession to name the sum which they think a fair remuneration for their services, when the late Dr. Fergusson, the Physician to the Queen, was in the habit of doing this? Surely anything that he did they may condescend with perfect grace to do! Strangers especially who come to Edinburgh for advice, feel the extremely awkward position in which they are placed by the present system, and we think it is time that some movement was made to have the whole matter considered and put upon a more satisfactory and sensible footing.

THE BURIAL OF POOR PERSONS.

UNDER the Vestry Act for many years in Ireland sums were granted for the interment of persons whose relatives were shown to be unable to afford the expense. That act was abolished two years ago, and no provision was made for the purpose under any other act. Great inconvenience arose, and in one instance in Dublin a body was retained during five hot summer days in the house where the relatives of the deceased resided. It was afterwards buried at the expense of the Union, the police having represented the matter as a nuisance. An act, however, has been introduced by Sir H. Bruce, Sir C. O'Loughlin, and Mr. Dawson, "to enable Boards of Guardians to bury poor persons who may not during life have been relieved out of the poor-rates." The only con-

dition is, that it must be certified that the relatives are unable to bear the expense of interment by a Guardian of the Electoral Division.

NEW CONVALESCENT HOME FOR EDINBURGH.

ABOUT a year ago an offer was made by a gentleman, who did not wish his name to be made public, to the managers of the Royal Infirmary, to erect a Convalescent Home for the benefit of patients who, after having undergone treatment in the Hospital, required a change of air to restore them to health. This offer was of course gladly accepted, but some difficulty was experienced in procuring a suitable site for the building. Attempts were made to get a fen near to the Royal Infirmary, but these were unsuccessful, and subsequently it was agreed to erect the Home at Corstorphine, on a piece of ground belonging to Sir William Ditch Cunyngham. The situation is all that could be desired as regards exposure and elevation, but it will be at an inconvenient distance from the city, and will cost the physicians and surgeons much time if they require to visit their patients frequently. The Home is intended to accommodate 44 inmates, and consists of a centre block of three storeys, from which wings extend east and west, of two storeys in height. The style of architecture is simple and inexpensive; nevertheless, the whole cost of the building will be close upon £12,000, and all this is to be borne by the generous donor of the gift.

NEW COLLEGE OF SCIENCE IN IRELAND.

THE following minute has been recently sanctioned by the Right Honourable the Lords of the Committee of Council on Education:—

"My Lords consider the minute of the 21st September, 1865, by which her Majesty's Government have decided to convert the Museum of Irish Industry into a College of Science for Ireland. As the sphere of action of this college on the basis broadly sketched out in this minute will be somewhat new and beyond the limits hitherto placed on the action of the Science and Art Department in respect of the encouragement of science, my Lords have appointed a commission to advise them on the subject. The following noblemen and gentlemen have consented to act on this commission:—

"The Right Hon. the Earl of Rosse, K.P., D.C.L., F.R.S., &c.; the Right Hon. the Lord Talbot de Malahide, F.R.S., &c.; Dr. Carpenter, M.D., F.R.S.; the Rev. B. M. Cowie, B.M.; John Fowler, Esq., President of the Institute of Civil Engineers; Professor Frankland, Ph.D., F.R.S.; W. H. Gregory, Esq., M.P.; Colonel Harness, C.B., R.E.; Professor Hofman, Ph.D., F.R.S.; Professor Huxley, F.R.S.; Professor Jukes, F.R.S.; Sir Robert Kane, F.R.S.; Myles O'Reilly, Esq., M.P.; Professor Lyon Playfair, C.B., LL.D., F.R.S.; Lieutenant-General Sabine, R.A., D.C.L., President of the Royal Society; Warrington W. Smyth, Esq., M.A., F.R.S.; Professor Sullivan, Ph.D.; Professor Tyndall, D.C.L., F.R.S.; Captain Donnelly, R.E., who will also act as secretary.

"My Lords consider that it is desirable that the College should, on its establishment, commence with a clear and defined object, a well considered course of study, and a staff of professors. They therefore request the commission to consider these subjects, and report generally on the scope of the instruction to be given, the examinations for testing it, and the certificates to successful students."

M. C. ROBIN announces, in a paper to the French Academy of Sciences, that he has discovered that the ray is an electric fish, though less so than the various species of the torpedo.

LUNACY ACTS (SCOTLAND) AMENDMENT BILL.

THE Lord Advocate has introduced to the House of Commons a Bill to amend the acts relating to lunacy in Scotland, and to make further provision for the care and treatment of lunatics, of which the following are the most important clauses:—

4. It shall not be lawful for the medical superintendent, ordinary medical attendant, or assistant medical officer of any asylum, to grant a certificate of insanity for the reception of any lunatic, not a pauper lunatic, into such asylum, except the certificate of emergency authorised by section fourteen of the third recited Act.

5. Section thirty-six of the first recited Act is hereby repealed; and, in lieu thereof, be it enacted, That if after the reception of any lunatic into any asylum or house it appears that any order or medical certificate upon which he was received is in any respect incorrect or defective, such order or medical certificate may be amended by the person who has granted the same at any time within *twenty-one days* after the reception of such lunatic: Provided, nevertheless, that no such amendment shall have any force or effect unless the same shall receive the sanction of the Board; and, failing such amendment, it shall be lawful for the Board to report such failure to the Sheriff, who shall, if satisfied that the original order or medical certificates are in any respect incorrect or defective, and of the failure to amend them, recall such original order.

6. Orders to remain in force, although patient absent from asylum, for fourteen days if the patient has escaped, and for three months if the patient is under the care of officers of the asylum.

7. The powers conferred by the Sheriff's order for the reception and detention of any lunatic in any asylum or house shall cease and determine with the notice of discharge of such lunatic given by the superintendent of such asylum or house to the board; and in no case shall the Sheriff's order remain in force longer than the *first day of January* first occurring after the expiry of *three years* from the date on which it was granted, or than the *first day of January* in each succeeding year, unless the superintendent or medical attendant of the asylum or house in which the lunatic is detained shall, on each of the said *first days of January*, or within fourteen clear days immediately preceding, grant and transmit to the board a certificate, on soul and conscience, according to the form of Schedule A hereunto annexed, that the detention of the lunatic is necessary and proper, either for his own welfare or the safety of the public.

8. Every pauper lunatic who is discharged on probation from any asylum or house shall remain subject to inspection by the Commissioners during the period of probation; and it shall not be lawful for the Parochial Board to take any such pauper lunatic off the poor's roll, or to alter the conditions on which probationary discharge was granted, without the sanction of the Board, during the period of probation; and every inspector of the poor who shall infringe these provisions shall be liable in a penalty not exceeding *ten pounds*.

9. It shall be lawful for any Parochial Board, by a minute at a duly constituted meeting, to direct that any pauper lunatic (not being a lunatic committed as a dangerous lunatic under the fifteenth section of the third recited Act) with whose maintenance it is chargeable, and who is detained in any asylum or house, shall be discharged or removed therefrom; and if a copy of such minute, certified to be a true copy by the chairman for the time of such Parochial Board, be produced to and left with the superintendent of such asylum, he shall, within *seven days* from the production of such minute, discharge such lunatic, or cause or suffer such lunatic to be discharged: Provided always that, on the written representation of such superintendent that such lunatic is dangerous to himself or the

public, or in any other way not a fit person to be discharged, it shall be lawful for the Board to prohibit the discharge of any such lunatic; and any inspector of the poor removing any pauper lunatic from an asylum or house against the written representation of the superintendent of such asylum or house, without the sanction of the Board, shall be liable in a penalty not exceeding *ten pounds*.

12. Section forty-one of the first recited Act is hereby repealed; and in lieu thereof no person shall receive or keep any person as a lunatic for gain, without the order of the Sheriff or the sanction of the Board; and any person who shall receive into his house any such person, or any person alleged to be a lunatic, shall, within *fourteen clear days* thereafter, make application for such order or sanction: Provided always, that when the lunatic is a pauper lunatic such application shall be made by the inspector of the poor; and it shall be lawful in such case for the Sheriff to grant his order on one medical certificate; and every lunatic shall be visited, as often as the Board shall regulate, by a medical person, who shall enter in a book to be kept in such house the date of each visit, and the condition of the mental and bodily health of the lunatic at each such visit; and any medical person who shall make any such entry without having visited the patient within *seven days* of making such entry, or who shall knowingly make any false entry in such book, shall be liable in a penalty not exceeding *ten pounds* for each offence; and it shall be in the power of the Board to order such inspection and visitation of every such house from time to time as to them shall seem proper, and to lay down and enforce such rules and regulations for the care and treatment of the lunatic as they may deem fit; and every person detaining or aiding in detaining any such lunatic, or any person who on inquiry is found to be a lunatic without the order of the Sheriff or the sanction of the Board, or after such order or sanction has been withdrawn, shall be liable in a penalty not exceeding *twenty pounds*.

15. It shall be lawful for the superintendent of any asylum, with the previous assent in writing of one of the Commissioners, which assent shall not be given without written application by the patient, to entertain and keep in such asylum, as a boarder, any person who is desirous of submitting himself to treatment, but whose mental condition is not such as to render it legal to grant certificates of insanity in his case: Provided always, that every such boarder shall be produced to the Commissioners at each of their visits to such asylum, that no such boarder shall be detained for more than *three days* after having given notice of his intention or desire to leave such asylum, unless on certificates of insanity and an order by the Sheriff being obtained, in which case neither of the certificates shall be granted by any medical person connected with the asylum, or having any immediate or pecuniary interest in it, and that notices of admission, discharge, and death with respect to all such boarders shall be made to the Board in the same manner as in the cases of lunatics.

20. It shall be lawful for the Sheriff to authorise the discharge of a dangerous lunatic from any asylum, on certificates being granted by two medical persons, approved of by the Procurator-Fiscal, that such lunatic may be discharged without risk or injury to the public or the lunatic.

21. It shall be lawful for the Board to enforce the rules and regulations which they shall make from time to time in relation to the books or minutes to be kept or made in asylums or houses, and the returns of entries therefrom to be made to the Board by the superintendents of such asylums or houses, by imposing a penalty for each infringement or violation thereof, not exceeding *ten pounds*.

MAGDALEN COLLEGE, OXFORD.—There will be an election at this college in April next to a Demyship in Natural Science of the value (room rent and tuition included) of £75 per annum, and tenable for five years from the day of election. The examination will commence on April 17th. Particulars relating to the examination may be obtained by applying to the president or senior tutor.

Notes on Current Topics.

CONVERSAZIONE OF THE OBSTETRICAL SOCIETY OF LONDON.

THIS very flourishing Society held a *Conversazione* on Wednesday last at the College of Physicians, which was very numerous attended. The object of the meeting, the preparations for which have occupied the attention of the Society for several months, was to collect and exhibit a series of Obstetrical instruments, of all ages and of all European countries, and to invite, for their display and inspection, the presence of distinguished foreign obstetric practitioners. The invitations were very cordially received and responded to, and contributions were sent from Russia, Sweden, Denmark, Germany, France, and Italy, as well as from home sources, covering the tables of the large library of the College in Pall-mall; and a goodly number of foreigners appeared among the company. The collection of instruments was arranged in such order as to represent historically the modifications in construction adopted in different times and countries, and they were also grouped according to their use, as perforators, cephalotribes, &c., in one group; forceps, vectes, &c., in another. Among the principal objects of interest were the original forceps of Chamberlen, the original Cephalotribe of Bandelocque, and a variety of curious antique obstetric instruments, the sphygmograph and sphygmographic diagrams, exhibited by Drs. Sanderson and Anstie; Dr. Richardson's apparatus for producing local anæsthesia, and, as is usual at these gatherings, there was a very interesting display of microscopes, photographs, micro-spectroscopes, &c., and the walls were adorned by some excellent paintings, and the staircases were lined with beautiful exotic plants. It should not be omitted to state that the refreshments were both excellent in quality and abundant in supply, and the whole of the proceedings gave the greatest satisfaction to the crowded assembly.

MEDICAL AND GENERAL SCIENCE IN INDIA.

WE are happy to welcome the appearance of the *Indian Medical Gazette*, two numbers of which we have received, and which is a "Monthly Record of Medicine, Surgery, Obstetrics, Jurisprudence, and the Collateral Sciences, and of General Medical Intelligence, Indian and European." In the introductory address published at the commencement of the first number, the editors express their sense of the great difficulties involved in their new undertaking, and they point to the great number of periodicals which have sprung up and declined in India, as a proof of the discouragement under which they labour. Nevertheless, medical science in India, as elsewhere, is rapidly advancing, and the treatment of diseases is now placed on a much more scientific basis than it formerly possessed; malarious diseases, for instance, are no longer treated by the administration of poisonous doses of calomel and exhausting bleedings, and we are happy to learn that the mortality from those affections has been most materially reduced. The immense resources of India, its abundant animal and vegetable products, its teeming population, and the high and deserved reputation of its medical practitioners, all render it most desirable that the accumulated stores of experience should be recorded for the benefit of the rest of the world and of posterity, and the numbers of the

Indian Gazette which have reached us appear to promise a new era of medical progress in the East. In one of the editorial articles in the second number on "Science in India," it is suggested that an association should be formed embracing all the local literary and scientific societies scattered over the great continent of Hindoostan, and incorporated into a General Association for the Advancement of Science, founded upon the model of that already existing in Great Britain.

PROPOSED SANATORIUM FOR BIRMINGHAM.

FROM a report forwarded to us in the *Birmingham Daily Post*, we find that it has been proposed to establish in the neighbourhood of that town an institution for the reception of convalescent patients, and that the suggestion has already been responded to in a most liberal manner. The origin of this sanatorium is derived from the surplus funds which have come to Birmingham from the contributions received on account of the cotton famine, and it should be mentioned to the honour of Birmingham that no less than £15,000 were contributed by that town to the relief of the distress in the cotton districts. At a meeting lately held for the purpose of carrying out the plan of the proposed sanatorium, the objects of the founders were explained, and numerous donations were announced. As is usual when works of benevolence are in contemplation, the members of our own profession took an active part in the proceedings, and in particular, Dr. Fleming and Mr. Pemberton strongly advocated the necessity of such an institution. In the course of his speech Dr. Fleming thus described the object of the sanatorium, the success of which has our best wishes:—

"Many persons (he said) on leaving our hospitals, though cured of their complaints, were so weak, that a return to their homes and ordinary employments was most hazardous. They were subject to continual relapses, and were obliged to return frequently to the wards of the hospital, and finally, becoming victims to chronic ill-health, were driven by sad necessity to the workhouse. Those physicians who, like himself, had visited the same wards for many years, soon became familiar with the faces of this class of patient. Indeed it could not be too plainly stated, that, for the most part, the dwellers in large and populous towns, who had suffered from serious diseases, required a short residence in the country for the full establishment of their health; but many were by reason of their poverty prevented from enjoying the advantage. The sanatorium would supply this want. Scientific medicine recognises, and has always recognised, the very natural division of remedial agents into two classes, the medicinal and hygienic—the former embracing medicine proper, and the latter including the normal conditions of health, pure air, good food, exercise, sleep, and amusement, which, variously modified, become most powerful agents in the treatment of disease. Both these modes of treatment had their proper place in the cure of all diseases, and in all stages of disease from the earliest beginning to complete recovery; but during convalescence and in many chronic ailments the hygienic remedies acquired for obvious reasons, relatively, a higher degree of importance than the medicinal, and it was for the more efficient application of the hygienic treatment of disease and of convalescence that it was proposed to establish the Sanatorium, and that in a situation which would enable them to command for the patients abundance of pure air, with ample and cheerful exercise. But while in the treatment of convalescence they assigned the first place to these hygienic means, it must not for a moment be supposed that they undervalued the importance of medicine, which, on the contrary, they recognized most fully, assigning to it, however, its true relative value.

It was the feeblest of feeble fallacies which jumped to the conclusion that, because of two modes of treatment one was proved to be good, the other must of necessity be useless or bad. Both in fact did, and they intended that in their Sanatorium—as in all other like institutions—both should conspire to give renewed health and strength to the patients.”

METROPOLITAN SANITARY ASSOCIATION OF LONDON.

DEPUTATION TO THE PRIVY COUNCIL.

ON Wednesday, March 14th, a Council of this Society formed a deputation, consisting of Mr. Shaw, Mr. Arthur Hall, Mr. Layard, M.P., Mr. Rendle, Dr. Sanderson, Dr. Hardwicke, Mr. Dresser Rogers, &c., was introduced by Mr. T. Chambers, Q.C., M.P., to Earl Granville at the office of the Privy Council. Mr. Chambers having briefly stated the objects of the deputation, Mr. Shaw then addressed his Lordship on certain resolutions of the Council which referred to amendments of the Metropolis Local Management Act, of which the following is a summary:—

1. That Parishes be required to provide a decent and suitable building for the reception of dead bodies, as under the Burial Act, and that so soon as such buildings shall be provided, it shall be unlawful to keep a dead body in any uninhabited house when the Medical Officer certifies it to be injurious to health, and the parties so keeping it to be liable to penalty. Parishes to be authorized to defray the expense of removal.

2. That whenever a Coroner shall find a body on which an inquest is to be held, in a room or house wholly unfit on sanitary grounds for such purpose, he shall have power to order its removal to the Mortuary Chamber of the District.

3. That the time for making orders or notices for intended buildings (under 18 and 19 Viet., c. 120, s. 76), to be in all cases within twenty-one days after notice, and that no drains be covered in till twenty-four hours' notice has been given to the Surveyor of the Vestry. The Vestry to have power to withhold sanction to any intended building or alterations, unless it is satisfied in respect of there being a sufficient space about the building when completed to secure a free circulation of air, and also in regard to the proper ventilation thereof.

4. When structural alterations of drains or other like works have been made by a vestry under the powers of the Metropolis Local Management Acts, if the owners cannot be found or cannot be made to pay the expenses (see 18 and 19 Viet., c. 120, s. 81, and 25 and 26 Viet., c. 10, s. 64), the magistrate to be authorized to give the vestry power to receive and compel payment to itself of the rents, till the amount due shall be liquidated.

5. That the power to compel a supply of water to houses, should not be limited to those, to which it can be done for 3d. a week (25 and 26 Viet., c. 102, s. 67), as thereby houses of a rent of above £20 per annum, or thereabouts, are excluded according to the present rate of charge of the Water Companies. That power be given to the local authorities to compel the Water Companies to supply water to pumps or taps in courts and streets at a definite rate of charge. Such taps to be so made as to prevent waste, and the Companies to be obliged to keep a constant supply of water. The Vestry, or Magistrate, on their application, to have power to order a pump or well to be disused if the water be injurious.

6. That some such powers as those given to the Commissioners of sewers in the city of London, by s. 10 of the City of London Sewers Act, 1851 (14 and 15 Viet., c. 91), with respect to a large class of lodging-houses not coming under the common Lodging-houses Act, should be extended to the metropolis generally, and vested in Vestries and District Boards.

7. That it would strengthen the hands of those members of Vestries, who are desirous of carrying forward necessary sanitary reforms, if the Privy Council had power,

upon the complaint of any twenty-six ratepayers in a parish, not only to make inquiries into the sanitary condition thereof, or of any particular part of it, but also to give notice to the Vestry to cause such alterations to be made or steps to be taken as the Vestry has power to do under the existing acts, and in default of the Privy Council, to have the power to cause the same to be done, and to issue their precept to the Vestry to raise the amount of expense out of the rates in like manner as the Metropolitan Board of Works now do.

8. That it is desirable that express power should be given to enable the Medical Officers to inspect workrooms, in the Metropolis, and (under certain limits) that power should exist to compel their ventilation, and to prevent their being overcrowded:—some analogy for such powers already existing in the Bakehouse Regulation Act.

FEVER IN LONDON.

A CONFERENCE of the Metropolitan Sanitary Association was held on Thursday last at Adam-street, Adelphi, when a paper on this subject was read by Mr. Wm. Rendle, one of the Vice-Presidents of the Association of Medical Officers of Health. Martin Ware, Esq., took the chair in the absence of Mr. McCullagh Torrens, M.P., who subsequently attended. The paper referred to the increasing prevalence of the disease, and the fact that it always referred to sanitary defects, remediable with a little trouble, typhus being no more nor less than a consequence of foul air chiefly from overcrowding. The wretched state of most of the dwellings of the poor was a source of much contagion, and the high rent paid for them, being far above their real value, deterred persons from erecting new and wholesome buildings, which probably would not fetch more rent. It was shown that the great majority of those attacked were between 15 and 45, 1720 in 2497 cases. That the chief supply to the fever hospital came from among the poorest, and that the age at which people began to work and provide is especially the age of fever. That those relieved by the guardians supply the largest number of fever cases, 3324 out of 3610, thus making it paragonably a poor-law question. It appears that about 290,000 cases of fever had occurred in London during the last fourteen years, the deaths being about one in eight. Cases were cited, showing how the disease spreads for want of very plain and simple precautions, all of which come legitimately within the scope of the powers of the local authorities. The different metropolitan boards were very deficient of inspectors; but several are now increasing their staff and appointing better men; there is, therefore, correspondingly more real work to be done. It was stated that 10,000 in a parish, and hundreds of thousands in London, are lodged in such miserable dwellings as to be literally, as it were, waiting for fever. The liberty of the subject and the inviolability of home appeared to be pleaded successfully against all great efforts to amend the dwellings of the working classes, but was of no avail against railways and the like, which, at least, in some instances, would dispossess thousands without the least chance of paying shareholders. In a deputation to Mr. Peabody's trustees it was urged, why not take some of the worst places, build cheap and wholesome habitations for the poor, so that we in all these localities might imitate you. The answer was, in most of these places there is a complication, and many interests we cannot buy, nor can we get a law which will enable us to deal with such matters. The franchise now discussed is said to be a trust and not a right; if so, the trustees are allowing hundreds of thousands to live in filth, vice, disease and wretchedness, and to be preyed upon by those who make a profit of all this wrong. The trustees must recognise their trust, as the franchise must be recognised as a right for every one, and not as a trust for a few who are, as it appears in this case, trustees for themselves only. It was suggested that, at any reasonable cost, healthier and better homes should be provided for the poor, and that houses should be regis-

tered when inhabited by many families; local hospitals should be provided for infectious diseases, so that the infected might be promptly removed from overcrowded close places; the prompt emptying and cleansing of infected houses, and allowing a time to elapse so as to make it safe to inhabit them again; better nursing and a better mode of supplying prepared sustenance for the poor; prompt information of infected or disease-producing houses by the poor-law officers; alterations of the poor laws or by-laws to meet those difficulties, it being more than any other a poor-law question; that many of the laws now permissive should be obligatory; and when it is the duty of the local authority to do certain sanitary work and neglects it, power of central authority to do it and charge the local authority.

The meeting was addressed by Mr. Bosanquet, Mr. Dresser Rogers, Mr. Lord, Mr. Beggs, Mr. Webber, Mr. B. Shaw, Mr. McCullagh Torrens, M.P., Mr. H. W. Rumsey, Dr. Hardwicke, Dr. Sanderson, Dr. Acland, F.R.S., and the Chairman; after which, a desire having been expressed to have the paper printed and widely circulated, the conference adjourned.

Parliamentary Intelligence.

HOUSE OF LORDS—MARCH 22.

Lord WESTMEATH drew attention to the frequency of street accidents, and condemned the conduct of the Home Secretary, who, he said, had taken no steps to prevent the loss of life and bodily injuries which were daily occurring.

Lord GRANVILLE admitted the necessity of some steps being taken to lessen the number of accidents which occurred in the crowded streets of the metropolis, but pointed out the difficulties which presented themselves to all the plans that had hitherto been suggested. The Government were most anxious to act efficiently, and there were no grounds for the attack upon the Home Secretary.

The subject was then allowed to drop.

MARCH 23.

The LORD CHANCELLOR, in moving the first reading of a Bill to amend the law relating to capital punishment, said that a few years ago Her Majesty appointed a Commission to inquire into this very difficult subject. The Commissioners had made their report, and he now proposed to lay on the table a Bill for carrying their recommendations, with some modifications, into effect. He intended to move the second reading of the Bill on April 17.

The Bill was read a first time.

Their Lordships adjourned until April 12.

HOUSE OF COMMONS.—MARCH 22.

In answer to a question by Lord H. LENNON, The CHANCELLOR of the EXCHEQUER said there was no correspondence between the Government and the trustees of the British Museum, and no decision had been taken as to filling up the post of principal librarian under the same conditions as it was recently held by Mr. Panizzi. In the view of the Government, the first step to be taken was to submit to that House the vote which they had given notice of their intention to propose for the erection of a building at Kensington; and they could take no other step of a definite character until the House had decided on that.

In answer to a question by Mr. NEATE as to the report of the River Commission,

Mr. T. J. BARRING said the report was now in the press, and would be presented to Parliament before the recess. That report related to the River Thames, to which the hon. member's question alluded.

The Labouring Classes Dwellings Bill, which enables Government to advance money on interest for the erection of suitable dwellings for the artisan and labouring classes, passed through Committee.

Mr. G. HARDY asked the Secretary for the Home Department what was the purport of the Orders in Council which were about to be issued on the subject of the cattle plague.

Sir G. GREY said that the purport of the new Order was the revocation of all the existing orders, with the view to the modification of the whole of the existing regulations with regard to the plague. Many of the conditions contained in the existing orders would at the same time be re-enacted, as for example those having reference to the appointment of inspectors, who would be required to give notice of the appearance of the disease in any particular district, and to see that the premises in which diseased cattle had been, were properly disinfected. It was desirable that a good many regulations of that description now in force should be renewed, and the new order would contain provisions with regard to the proclamation of infected districts and the prohibition at certain times of all markets and fairs, except those held under the licence of the Privy Council. With respect to the removal of cattle, it was intended to extend the provisions of the existing Act until April 16, and to substitute a regulation authorising the removal of cattle by railway or by highway under certain licences, some of which would be left to be granted by the local authorities, and others would be provided for in the schedule. It was intended that the substance of this Order, or the greater part of it, should not come into operation until April 16; but part of it would come into operation immediately, and it would be in the possession of the Courts of Quarter Sessions in the week after next.

The House adjourned until Monday, April 9.

ARMY MEDICAL EXAMINATION. CHELSEA HOSPITAL.

MARCH, 1866.

SURGERY.—MR. PRESCOTT HEWETT.

1. Epulis; morbid anatomy, diagnosis, prognosis, and treatment.
2. Diagnosis, prognosis, and treatment of laceration of the kidney from a blow or fall.
3. Enlarged ceynoidal cysts of the popliteal space; their diagnosis and treatment.
4. The diseases of the sacro-iliac joint; their diagnosis and treatment.
5. Hæmatocele; morbid anatomy, diagnosis, prognosis and treatment.

ANATOMY AND PHYSIOLOGY.—MR. BUSK.

1. Describe the medulla oblongata, arranging your answer according to the following order of subjects:—
 - a. General form, dimensions, and relations to the surrounding parts.
 - b. The bloodvessels by which it is supplied, and their mode of distribution.
 - c. The minute structure, noticing especially the disposition of the white and grey substance in the different parts of the medulla.
 - d. The connexion of the various parts with the cerebrum, pons, cerebellum, and spinal cord.
 - e. The nerves arising from the medulla, tracing them to their ultimate origins.
2. Explain the mechanism of inspiration and expiration, and the nature of the process by which the interchange of gaseous constituents between the blood and the air is effected.
3. Describe the dissection required to expose the external circumflex artery of the thigh from its origin to the termination of its branches, noticing in their proper order the parts brought into view in the dissection.
4. Describe in their proper order the parts brought into view when the trapezius muscle is removed.
5. Describe the structure of the eye regarded simply as a dioptric instrument, and in doing so explain the mode in which the images of external objects are formed on the retina.

MEDICINE.—DR. PARKES.

1. Enumerate the different forms of paralysis depending on disease of the brain and spinal cord, and describe the causes and post-mortem appearances.

Give the symptoms of hemiplegia caused by acute softening of the brain.

2. What are the chief causes of pericarditis? Give the physical signs fully. Describe the effects on the heart produced by universal firm adhesions.

3. Give fully the treatment of the two following diseases, including the possible complications: typhoid, or enteric fever, scarlet fever.

4. What are the chief causes and symptoms of peritonitis?

5. Under what circumstances are the preparations of zinc, bismuth, and silver employed in medicine? What are the principal pharmacopœial preparations of these metals and their doses?

6. How would you detect and remove a retained placenta after delivery?

NATURAL HISTORY.—DR. HOOKER.

(Optional.)

1. Give the essential distinctive characters of the classes of vertebrata.

2. What is meant by the term "alternation of generation?" Give instances of animals in which it occurs.

3. Give the distinguishing characters of the class Insecta, and name a genus belonging to each of its principal orders.

4. Give an account of the metamorphoses of insects.

5. Describe the structure and functions of the stomata in plants.

6. Give an account of the different kinds of placentation in plants.

7. Describe the different parts of the vegetable ovule and seed.

8. Give the essential characters of the natural orders Leguminosæ, Gramineæ, Musci.

9. Explain the theory of the production of dew.

10. Where do trade winds blow? What is their direction, and how do you explain their occurrence?

11. Explain the action of the different kinds of lever, and illustrate them by examples taken from the articulations of the human body.

12. Explain the terms sedimentary, metamorphic, volcanic, tertiary, secondary, palæozoic, as applied to rocks.

13. In what strata is coal usually found, and what is supposed to be its origin?

14. What is meant by the glacial epoch in geology, and what was its general influence on the surface of Great Britain?

EPIDEMIOLOGICAL SOCIETY.

The President (Dr. Milroy) and Council of this Society invite the attention of members to the three following questions, relating to the provision for the reception and treatment of poor in the event of an outbreak of cholera in this country, what kind of accommodation should be proffered as most calculated for the benefit of the patients and least likely to endanger public health:—

I. Can persons suffering from cholera be admitted into the ordinary wards of general hospitals or infirmaries without danger to the health of other patients?

II. Can cholera patients be admitted into special wards, set apart for the disease, in general hospitals and infirmaries, without undue risk of the extension of the malady to the other inmates of the institution and their ordinary attendants?

III. Do you deem it necessary that special hospitals should be provided for the reception of persons attacked with cholera? and that such persons should not, on any conditions, be admitted into general hospitals or infirmaries?

METROPOLITAN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

ON Saturday, March 18th, the adjourned meeting of this Society discussed the paper of Mr. Beggs, "On the Dwellings for the People of the Metropolis." The chair was taken by Mr. Rendle, and the addresses on the question were by Mr. Liddell and Mr. Beggs. A resolution was then passed, that the standing committees should take the subject into their consideration with reference to any improvements that might be suggested in their amendment of the Metropolis Local Government Act.

RETROSPECT OF THE MEDICAL JOURNALS.

MARCH 31.

THE *Lancet* draws attention to the proposed amendment to the Medical Act which has been so inefficacious. Sir George Grey has communicated with Dr. Burrows, and the latter is now engaged with the Law Adviser to the Home Office in framing a Bill which shall have the effect of preventing quackery. The legal community are very careful in all legal enactments affecting their body to exclude any from the practice of their profession unless those properly qualified. Let us hope that they will not grudge us the same privileges. Our contemporary regrets the action of the Medical Council at its last session in that they refused to register the degree of Bachelor of Surgery of the University of London.

The operations of the Nightingale Fund are reviewed. It may be remembered that the munificent fund subscribed by the people of Great Britain, nearly £50,000, was allocated by Miss Nightingale for the purpose of training nurses. It seems that very little good has been done for the very large outlay, the principal portion of the sum being absorbed by salaries, &c. The average cost of each of the nurses so trained has been £88, and most of them have been absorbed by the institutions in which they received their education. The *Pall-mall Gazette* has directed a good share of public attention to the lavish expenditure of a fund originally intended for a charitable object.

The verdict of the coroner's jury in the case of the child laid out for burial at St. Pancras Infirmary was as follows:—"The jury are of opinion that great blame is to be attributed to the workhouse attendants for tying up the jaws of the deceased and treating her as dead for some time before she had wholly expired. They are further of opinion that there is not a sufficient number of paid medical attendants and nurses to perform the duties of so large an establishment as St. Pancras Workhouse; and the jury beg to express their approval of the course taken by Mr. Hillocks in bringing the matter before the public."

In reference to this very subject Dr. Aldis writes to the *Lancet* that in 1850 he contributed a paper to that journal, entitled "The danger of tying up the lower jaw immediately after supposed death." He was asked for a death certificate for an infant who was brought to him with the jaw tied up, and supposed to be dead. This happened on a Friday. The bandage was removed and the child lived until the following Monday.

Dr. Watson's address on the occasion of his being elected for the fifth time President of the College of Physicians, was delivered in his usual lucid and learned style. He dwelt principally on the losses by death which the College had sustained during the year, and he spoke in the most kindly manner on the respective merits of Drs. Southey, Ferguson, and others, whose loss the public as well as the profession has to mourn.

A person has been nearly poisoned by castor seeds. "The unfortunate man lies in a very lamentable condition; his recovery is extremely doubtful. It is not commonly known that the seeds from which castor oil is extracted contain in the embryo a very active poison, and that a few of them are sufficient to produce violent purging and death."

Mr. Henry Lee, in his lectures on syphilitic inoculation in 1865, gives the results of some experiments carried out by himself. In his next lecture, we are promised his views on the subject of syphilisation. We are still at sea with regard to this very intricate question involving the nature of the syphilitic virus.

The *British Medical Journal* again draws attention to the injury to their cause inflicted by the Naval Medical Officers. It reviews the contents of Dr. Brown's pamphlet, entitled "Comments on the Recommendations of the Committee." Dr. Brown has made one great mistake; he proposed a scale of pay and regrets that it was not adopted; but our contemporary shows that the recom-

mendations of the Committee proposed to grant even a higher scale than that of Dr. Brown.

"A Prussian ministerial journal contains an article which asserts that the trichina disease is nothing but a revolutionary proceeding, got up by the enemies of the government. This, no doubt, on account of (politician) Virchow's name being connected with the trichina.

"Dr. Fiedler says that the trichinae may find their way into the muscles through the current of the blood is proved by the facts: that he has frequently found trichinae in coagulæ of the right auricle and ventricle; and that at times, even in the most distant muscles, trichinae are found not exceeding in size those found in the abdomen.

"Professor Klob says that the use of raw meat in Prussia and Saxony has become of late years very common. The workmen have no means of cooking, or will not take the trouble to cook their meat; and consequently find that raw pork, minced, &c., is the most convenient food.

"Dr. Thudichum states that a preparation from the biceps of a child, aged five and a half years, which died on the seventy-ninth day, was found to contain fifty-eight trichinae. The preparation being estimated to weigh one-fifth of a grain, one grain of such muscle would contain on an average one hundred trichinae. Dr. Thudichum calculates that an adult victim to trichiniasis may have as many as twenty-eight millions, if his entire muscular system be affected in the ratio as the child's biceps just mentioned; and that although their individual length is but about five millimètres (0.2 inch), the whole length of these twenty-eight millions put together would extend to ninety miles."

A new method for the dissemination of syphilis has been brought to light; it puts us in mind of the aphorism promulgated by a late eminent writer on this disease, that married men and clergymen always contracted the disease from water-closets:—"The *Gazette Médicale de Lyon* reports another instance of syphilis communicated to a patient through catheterism of the Eustachian tube; and by the aid of the same specialist who has already become famous in Paris in this way as a distributor of syphilis. The fact of his repeated offences has been authenticated by Ricord and the highest surgical authorities in Paris, or such gross carelessness as is indicated in the proceeding would have been hardly credible."

The *Medical Times* and *Gazette* has a leader on the subject of the equalization of the metropolitan poor-rates, a scheme which it deprecates.

It also refers to Dr. Bence Jones's communication made last week to the Royal Institution. He has discovered a substance which has never been even thought of—a substance in the different tissues of living animals resembling quinine; as yet he has been unable to isolate it, but he has demonstrated it by the well-known effects of this body in refracting light. It has been found in the crystalline lens:—"The demonstration of its presence in the crystalline lens gave ground for hope that substances might be found hereafter to remedy perverted nutrition of the non-vascular tissues—as cataract, and even the deposits of gout in cartilages. Then, what a glimpse these investigations afford of the possible *modus operandi* of quinine in the cure of ague! We call quinine a "specific"—a term which indicates our notions—or want of notions—of its action, and nothing more. But is it not possible that ague may depend on the absence of a natural quinine-like substance from the tissues? that quinine may supply this want—(thus, by-the-by, showing the futility of all attempts to distinguish between food and physic),—and that arsenic, on the other hand, may act within the body as it does without, by preserving certain matters from decomposition?"

Dr. Maudslayi having dissected the bodies of many lunatics, has found, that with very few exceptions, the internal carotid arteries are dilated, even to the extent of being aneurismal, at their origin from the common carotid. He has likewise observed that the vessel is invariably atheromatous.

TRICHINOSIS.

PROFESSOR DELPECH of the Paris Faculty of Medicine, and Professor Reynal of the Imperial Veterinary School at Alfort, who were charged with a mission to study the above-named disease in Germany, both in human beings and other mammals, have just presented to the Minister of Agriculture, Commerce, and Public Works a report of the results of their investigations at Huy (Belgium), Hanover, Magdeburg, Berlin, Halle, Dresden, Leipsic, and Mayence. To render their investigations more complete, they solicited and obtained the coöperation of most of the eminent German Physicians, who had made the disease in question their especial study. The chief practical facts ascertained are as follows:—"The epidemic trichinosis lately prevalent in Germany has now almost entirely disappeared. The mortality was everywhere slight, except at Hadersleben. At Zwickau, Seltendorf, and Sommerfeld, there were 88 patients, not one of whom died. In every case the disease was caused by eating imperfectly cooked pork containing trichines, a case of rather frequent occurrence in Germany. In Hanover, in 21 months, out of 25,000 pigs 11 were found full of trichines, 16 out of 14,000 in Brunswick, and four out of 700 in Blakenburg. The animals while living show no signs of their presence, nor can they be detected in the meat with an ordinary magnifying-glass, but a powerful microscope renders them distinctly visible. The utility of a microscopic inspection of pig's flesh by competent observers is so evident that many of the German governments have rendered it obligatory, and MM. Delpech and Reynal would not hesitate to recommend it in any country contaminated with trichinosis, but they think it unnecessary in France, where no case of the disease has yet been noticed. In Germany the hospitals receive many patients suffering from this affection; during last year there were thirteen at Magdeburg, of whom only one died. Post-mortem examinations have also shown, among persons who died from other diseases, numerous cases of old trichinosis cured by the encystment of the parasites. The proportion of these at Leipsic has been about six per hundred. In places where the complaint prevails, the rats which infest slaughterhouses are found to have it, as proved by Leisering at Dresden, Adam at Augsburg, and Roll at Vienna. Since their return, MM. Delpech and Reynal have examined many of these animals as well as pigs without finding a trace of trichines. Consequently, there is no reason in France for any person to refrain from eating hogs' flesh, especially when so thoroughly cooked as is usual among the French. In Germany, on the contrary, many of the peasantry eat it almost raw or only smoked. The most timid may safely eat the heart, kidneys, brain, and fat of pigs, as those parts never contain trichines. MM. Delpech and Reynal assert, as an undoubted fact, that a temperature of 75 deg. C. (167 Fah.) is sufficient to kill trichines. Meat thoroughly salted is also perfectly safe. Smoke-dried sausages, which have been kept a long time, are considered free from danger, but the wisest plan is to give them a good boiling. The authors of the report attribute the spread of the disease among pigs to the fact that they are foul feeders and will eat any offal, such as the dead bodies of rats and other animals, which are now known to be liable to trichinosis. Great care ought therefore to be taken to keep such things out of their reach. MM. Delpech and Reynal likewise advise all experimenters never to throw away trichinized flesh, but to burn it as soon as their examination is completed; for a fragment of it carelessly exposed might be eaten by a rat, the rat devoured by a pig, and this last become the cause of fatal accidents. They recommend farmers to be very cautious in feeding their pigs, to avoid giving them offal flesh without first boiling it; to destroy rats and other small carnivorous animals; and never leave human or other excrements in places where pigs can go. The Government has deemed it expedient to publish at once the above abstract of MM. Delpech and Reynal's report, which it has also submitted to the consideration of the Consultative Committee of Public Health.—*Galvani*.

LITERARY PIRACY.

THE *Philadelphia Medical Reporter* exposes, in its issue for February 17th, the following shameless fraud:—

"There was issued from the press of Lindsay and Blekiston of this city, during the last quarter of 1864, a *brochure* entitled 'Glaucoma: its Symptoms, Diagnosis, and Treatment,' by Peter Direk Keyser, M.D., with copyright secured to this latter individual. This *brochure* was sent to us, and received, as its contents really merit, a favourable notice, in our first of January number, 1865. Unfortunately, at that time we had not seen a *brochure* published in London, by John Churchill and Sons, entitled: 'Glaucoma, and its Cure by Iridectomy, being four lectures, delivered at the Middlesex Hospital, by J. Soelberg Wells, Ophthalmic Surgeon to and Lecturer on Ophthalmic Surgery at the Hospital.'

"In April, 1865, Keyser's *brochure* was noticed by the *Boston Medical and Surgical Journal*, and attention called to the fact that it was 'copied word for word from Dr. Wells' pamphlet, not only not adding anything, but leaving out some important portions, and all the plates in explanation of the operation of iridectomy.' This notice in the *Boston Journal* escaped our attention, until, on receipt of Dr. Wells' lectures, and comparing them with Keyser's pamphlet, all the facts became apparent, and nothing remains but to arraign the latter before the profession, as guilty of the most flagrant literary theft.

"Dr. Keyser has the impudence to say in his preface, that 'the substance of this work is from my notes taken while attending the clinic lectures of Professor Von Graefe, during the winter of 1863 and 1864, in Berlin, and I have compiled and published them, thinking that they would not only be of interest, but of advantage to the medical profession in this country.' This preface is dated September, 1864. It is from beginning to end a most 'graceless assumption of truth,' for the substance, nay, the whole of this work is copied verbatim et literatim, from Dr. Wells' lectures, the preface of which bears date April, 1864.

"A more unmitigated fraud has never been perpetrated upon the medical profession of this country; and while we apologize, with the *Boston Journal*, to the profession of England and to Dr. Wells, for the insult and injury done, we ask every physician who owns the book, to blot out the preface, and the name of Peter Direk Keyser, M.D., from the title page, and insert in its place J. Soelberg Wells."

ALLEGED POISONING BY MISTAKE.

LEWES, MARCH 21.—Richard Noakes, a chemist and druggist at Brighton, was indicted for the manslaughter of one Samuel Boys in August last, by the administration of aconite by mistake. Mr. Boys, the deceased, was an old gentleman of the age of 80, who resided at Lansdown-terrace, Brighton, and suffered from disease of the heart. He had been attended by a Dr. Dill, who had prescribed for him 30 drops of henbane, to be taken occasionally, with a view to his relief. It was admitted that on this occasion the prisoner himself had filled the bottles, which were sent to the house of the deceased, and given to his servant; and there was no doubt that they found their way to the medicine chest of Mr. Boys. On the night of Sunday, the 20th of August, he felt an attack of his disorder, and said he would take a dose of the henbane, which he then accordingly did take, measuring it out himself in a "drop glass," as it is called, which measures the number of drops. The dose, it will be borne in mind, was thirty drops (which was written on the outside of the bottle), and there was no reason to believe that it had been exceeded. Upon swallowing it, however, he observed that it "felt hot." About a quarter of an hour afterwards he said his limbs had become benumbed. After this he felt sickness. He became alarmed and looked at the bottle, having a suspicion that there was some mistake: but on looking at it and seeing it marked "henbane," he said, "it's all right." He was extremely ill all night, and early in the morning desired that the bottle should be sent to Mr. Noakes to see if it was right, retaining, however, a portion of it in the house. Not long afterwards he became drowsy, and in the course of the hour he died. The attention of the medical men was directed to the contents of the bottle in question, and they were satisfied from its pungent taste that it was aconite. A post-mortem examination, however, disclosed the seat of the cause of death was the heart. The jury returned a verdict of not guilty.

The summing up of Chief Justice Erle will explain the law

of the case, as to responsibility, &c. "He put it to the jury whether they deemed it a case in which they could call upon the prisoner for his defence, or whether they would not rather say that it was a case in which the evidence was not sufficiently clear to warrant them in finding a party guilty of felony. They could not commit in such a case unless clearly and firmly satisfied that there had been a culpable degree of negligence, and that it had caused death. Now, as to the first point, there was no judge who would go further than he would in demanding from a chemist a great degree of care in sending out the powerful and dangerous drugs in which he dealt. But this was the case of a chemist put out of his ordinary course and not allowed by his customer to use his own ordinary precautions, but desired to send the medicines in bottles which the customer chose to send for them. Moreover, it was the case of a chemist whose customer had dealt with him for several years in aconite, and had only once or twice for henbane. No doubt the bottle in which he aconite was sent had upon it a label bearing on it the word "henbane," and then, in smaller letters, "30 drops," and it might be said that the prisoner ought to have read those words. But without saying that there might not have been evidence in a civil action, he should certainly pause before he concurred in a conviction for felony on that ground. Then, as to the second point—the cause of death,—the jury must be satisfied, before they convicted, that the death was caused by the alleged negligence. But one of the medical witnesses for the prosecution stated that he could not say that the aconite had anything to do with the death, though it might have accelerated it; the other stated that it had not. Under these circumstances, could the jury safely convict of felony?"—The jury, after a few moments' consultation, returned a verdict of "Not Guilty," which was received with some applause.

PREMATURE INTERMENT.

A PETITION has been presented to the French senate "pointing out the danger of hasty interments, and suggesting the measures requisite to avoid terrible consequences." The petitioner demands a space of twenty-four hours. A debate followed, in which Cardinal Donnet, Archbishop of Bordeaux took a leading part. He said he had the very best reasons for believing that the victims of hasty interments were more numerous than people supposed. In the village where he was stationed as assistant-curate in the first period of his sacerdotal life he saved two persons from being buried alive. He gave other cases and then related the following:—"In 1826, on a sultry day, in a church excessively crowded, a young priest, in the act of preaching, was seized with giddiness. His words became indistinct, he lost the power of speech, and sank down on the floor. He was carried home. All was thought to be over. Some hours afterwards preparations were made for the interment. His eyesight was gone; but he could hear, and what reached his ears was not calculated to reassure him. The doctor came, examined him, pronounced him dead; and after the usual inquiries as to his age and the place of his birth, &c., gave permission for his interment next morning. The venerable bishop in whose cathedral the young priest was preaching when he was seized with the fit came to his bedside to recite the *De Profundis*. The body was measured for the coffin. Night came on, and inexpressible was the anguish of the living being in such a situation. At last, amid the voices murmuring around him, he distinguished that of one whom he had known from infancy. That voice produced a marvellous effect and a superhuman effort. Of what followed I need say no more than that the seemingly dead man stood next day in the same pulpit. That young priest, gentlemen, is the same young man who is now speaking before you, and who, forty years after that event, implores those in authority, not merely to watch vigilantly over the careful execution of the legal orders with regard to interments, but to enact fresh ones in order to prevent the recurrence of irreparable misfortunes."

In Stillman's *American Journal of Sciences and Arts*, for January, is an interesting paper, "On the Crystalline Nature of Glass," by Dr. C. M. Wetherill. By carefully attacking glass, of every variety, with hydrofluoric acid, he finds, upon microscopic examination, the presence of crystals, which vary with the different kinds of glass. The detection of the crystalline nature of glass demonstrates that we are yet unacquainted with the true nature of this complex substance.

A POETICAL PRESIDENT.

At the centenary meeting of the Medical Society of the State of New Jersey, Dr. Coles, the President, celebrated the hundredth anniversary of the Society by an address in verse, which occupies three or four columns of the *Philadelphia Medical Reporter*—*Fiat exemplum*. Here is Dr. Coles's rhyming of a skin dissection:—

When that, the dermal, covering is cut through,
And its interior structure brought to view,
Pause if you will, and let your aided sight
Peruse the wonders of creative might.
Admire the skill that can in one combine
A sensibility and a touch so fine—
Making the skin throughout the purpose serve
Of one ubiquitous, great surface nerve,
That finest needle, would it entrance gain,
Must pierce the sense and stab the soul with pain,—
Where camping armies of papillæ wait,
Manning each fortress, guarding every gate,
Armed at all points, and vigilant as fear,
To sound the alarm, when danger hovers near,
And yet, despite the nicety of sense,
Formed for coarse uses and for rough defence.

THE HEALTH OF THE CITY OF DUBLIN.

The following is the report of the health of Dublin for the four weeks ending March 24, by E. D. Mapother, M.D., medical officer of health:—During the past four weeks the deaths recorded by the Registrar-General have numbered 660 against 611 during the preceding month, and 619 during the corresponding period last year. The death-rate was therefore 1 in 386, while it was in other cities as follows:—London and suburbs, 1 in 414; Central London, 1 in 440; Liverpool, 1 in 238; Glasgow, 1 in 382. In the seven dispensary districts of the city the rates of mortality were:—Summer-hill, 1 in 528; Coleraine-street, 1 in 486; Blackball-street, 1 in 202 (or excluding workhouse deaths 1 in 415); Meath-street, 1 in 244 (or excluding workhouse deaths 1 in 515); High-street, 1 in 393; Peter-street, 1 in 408; and Grand Canal-street, 1 in 830. Zymotic diseases caused 108 deaths, against 130 during the last month, and 104 during March, 1865. Of this class fever, against which preventive measures are most successful, produced 40 deaths, against 50 and 47 during the preceding and corresponding months. 23 cases were admitted into the Hardwicke and Cork-street Fever Hospitals, especially from the following neighbourhoods:—Francis-street, New-street, Tighe-street, George's-quay, North King-street, and Dispensary-lane. 242 cases were admitted during last month, and 311 during March, 1865. Diarrhoea caused 17 deaths; consumption was fatal in 86 cases, and bronchitis in 158. This latter disease has raised the comparative death rate, having caused but 109 deaths during the preceding month, the average temperature having been then three degrees higher and the rainfall more than one-third less. Whooping-cough caused 19 deaths, and diphtheria 5. The Inspector of Nuisances and his assistants visited 323 houses complained of at the City-Hall, or in which it was ascertained by the list furnished by the Registrar-General and the fever hospitals, that preventible diseases had arisen; 86 nightly lodging-houses, 22 bake-houses, 125 slaughter-houses, and 3 knackers' yards. The sanitary sergeants of the police inspected 914 houses set in tenements, in which 6,018 sanitary defects such as broken roofs, window sashes wanting, or replaced by boards, general filth, and want of house drains, from which the yards became dangerous nuisances, were discovered. The owners of many of these houses have as yet successfully resisted our bye-laws. These officers have also visited 832 houses, and found that 2,324 defects before noticed have been remedied. The principal neighbourhoods inspected for the first time were Watling-street, Kilmainham, Clanbrasil-street, Brides'-alley, Spring-garden, Beaver-street, Church-street, and Back-lane, and for the second time Meath-street, James's-street, Mercer-street, Cuffe-street, Barrack-street, George's-quay, Townsend-street, Great Britain-street, and Tighe-street. The

need of legislative regulation of places where various industrial occupations are conducted, is shown by several cases submitted to you.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a general meeting of the Fellows held on the 26th ult., Thomas Watson, M.D.Cantab., D.C.L.Oxon., was unanimously re-elected the President of the College for the ensuing year. At the same meeting, the following gentlemen, having undergone the necessary examination, were duly admitted Members of the College:—

Fox, William Tilbury, M.D.Lond., Sackville-street.
Livinge, Robert, M.D.Cantab., Hurley-street.
Parson, Edward, M.D.Lond., York-street, Portman-square.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 22nd ult.:—

Basan, Horace, Castle-street East, Berners-street, W.
Finch, John Edward Montague, Salisbury.
Loane, Joseph, Dock-street, E.
Roberts, Thomas Edward, Gibraltar.

The following gentlemen also on the same day passed their first examination:—

Clag, George Langsford, Queen's College, Birmingham.
Hay, Richard Francis, London Hospital.
Howse, Frederic, Charing-cross, Hospital.

PORTUGAL.—The Government is taking sanitary precautions against the cholera.

HARVEIAN SOCIETY OF LONDON.—The next meeting of this Society will be held on Thursday, April 5th, at 8 p.m., when a paper will be read by Mr. Haynes Walton "On Detachments of the Retina; their causes and treatment, with specimens."

SMALL-POX AMONG SHEEP.—It is stated that there is no foundation for the report of small-pox among sheep having been brought from Denmark, as since 1862 Denmark has been entirely free from the disease.

CAPITAL PUNISHMENT.—At the last meeting of the Society for the Abolition of Capital Punishment, Mr. Sergeant Woolrych read a paper on the subject, and several gentlemen took a part in the discussion of this most important question.

UNION CHARGEABILITY.—The Act for the better distribution of the charge for the relief of the poor in unions came into operation on Tuesday week. Unions under local acts may avail themselves of the new law, which is to be cited as "The Union Chargeability Act, 1865."

THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.—On the 21st ult. the eighteenth anniversary festival of this valuable charity was held at the London Tavern. The total amount of donations received was £2560, and of annual subscriptions, £1561.

TESTIMONIAL TO A SURGEON.—A valuable microscope has been presented to James Tily, Esq., of Walkern, Herts, surgeon, in recognition of his professional talent during a three years' stay at Hitchin, and for the high esteem in which he was held by his patients.

THE LATE DEATH IN A TRAIN.—It is said that the coroner of Doncaster, Mr. John Lister, surgeon, has placed himself in communication with Sir George Grey to ascertain whether it was legal to remove the body from the station and permit it to go on to its destination.

BATH UNITED HOSPITAL.—The funds of this institution have just been augmented by a legacy of £300, under the will of Miss Maria Renton Tufnell of Bath, who has also directed that her furniture, linen, plate, china, glass, and other effects be sold and the proceeds handed over to the same medical charity. This benevolent lady bequeathed legacies to other institutions not strictly medical, and all to be paid free of legacy duty.

Dr. Sieveking's Croonian lectures on the Localisation of Disease, are continued at the College of Physicians.

Notices to Correspondents.

Dr. Moore's Clinical Lecture on Paralysis after Diphtheria shall appear in our next.

Inquirer.—The existence of human bones has not yet been proved in those localities where the flint implements are found, or at least the statements as to their existence have not yet been adequately confirmed.

A Stranger in London.—The Museum of the College of Surgeons of England is open on Mondays, Tuesdays, Wednesdays, and Thursdays, from 12 till 4.

Philos.—The practice has been adopted in some quarters, but we cannot take upon ourselves to recommend it.

A Union Surgeon.—The assistant must be qualified.

The Harveian Society.—The notice has been received.

Mr. Griffin's letter is inserted.

Dr. E.—The newspaper has been received.

Dr. B.—The subject is noticed in another part of our Journal.

McDougal's Powder.—In a letter published in the columns of the *Staffordshire Advertiser*, Dr. Berry King calls attention to the fact that Dr. Angus Smith, although he denies being in any way concerned in the sale of the above powder, is a co-patentee with Mr. McDougal in its manufacture. Dr. Berry King questions the disinfecting efficacy of the McDougal powder, and considers that the only real disinfectant is oxygen, and that a substance which contains the most oxygen is the best disinfectant. Such a substance is found in Condy's disinfecting fluid, which contains permanganate of potash.

A. J.—Robbins' patent oxygenesis is a mixture of peroxide of barium and bichromate of potash. This mixture liberates oxygen on adding any diluted acid.

Contributors are requested in all cases to forward their communications direct addressed to the Editor of the special department of the Journal in which they reside. Considerable delays have arisen in consequence of matter from England being forwarded to the Editor of the Irish or Scotch Departments, it being necessary to reforward them to London, for revision before publication.

Original Communications, Hospital Reports, Society Proceedings, and other matter of considerable length, should reach our Office not later than FRIDAY EVENING for insertion in the following Wednesday's issue. No exception to this rule can be made. Important information—Telegraphic News, and other matter occupying only a short space—can be received up to Monday evening.

Authors' corrected proofs must in all cases be returned to the Office not later than 10 o'clock on MONDAY MORNING, and no alterations can be attended to after that date.

Medical Diary of the Week.

WEDNESDAY, APRIL 4.

MIDDLESEX HOSPITAL.—Operations, 1 p.m.
ST. MARY'S HOSPITAL.—Operations, 1½ p.m.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ p.m.
ST. THOMAS'S HOSPITAL.—Operations, 1½ p.m.
GREAT NORTHERN HOSPITAL.—Operations, 2 p.m.
UNIVERSITY COLLEGE HOSPITAL.—Operations 2 p.m.
LONDON HOSPITAL.—Operations, 2 p.m.
MICROSCOPICAL SOCIETY.—8 p.m.
METROPOLITAN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—4 p.m.
ROYAL COLLEGE OF PHYSICIANS.—5 p.m. Dr. B. W. Richardson: "Physical Researches in Pathology and Therapeutics."
OBSTETRICAL SOCIETY OF LONDON.—7 p.m. Meeting of Council.—8 p.m. Dr. Battye, "On certain Uterine Affections in their relation to Phthisis."—Mr. Robt. Ellis, "On a New Mode of Inducing Anæsthesia by Compound Vapours."—Dr. Greenhalgh, "On a Case of Obstructive Dysmenorrhœa."
HUNTERIAN SOCIETY.—7½ p.m. Meeting of Council.—8 p.m. Dr. J.R. Bennett, "On certain Derangements of the Nervous System occasioned by Shock, especially in reference to Railway Accidents."

THURSDAY, APRIL 5.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 1 p.m.
ST. GEORGE'S HOSPITAL.—Operations, 1 p.m.
LONDON SURGICAL HOME.—Operations, 2 p.m.
WEST LONDON HOSPITAL.—Operations, 2 p.m.
ROYAL ORTHOPEDIC HOSPITAL.—Operations, 2 p.m.
HARVEIAN SOCIETY OF LONDON.—8 p.m. Mr. Haynes Walton, "On Detachments of the Retina, their Causes and Treatment; with Specimens."
NATURAL HISTORY SOCIETY OF DUBLIN.—8½ p.m. Dr. A. Macalister, "On a few Remarkable Muscles in Monkeys."

FRIDAY, APRIL 6.

WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1½ p.m.
ARCHÆOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—4 p.m.
ROYAL COLLEGE OF PHYSICIANS.—5 p.m. Dr. B. W. Richardson: "Physical Researches in Pathology and Therapeutics."
WESTERN MEDICAL AND SURGICAL SOCIETY OF LONDON.—8 p.m. Mr. J. R. Lane, "On some Points connected with the Pathology of Syphilis."

SATURDAY, APRIL 7.

ST. THOMAS'S HOSPITAL.—Operations, 9½ a.m.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1½ p.m.
KING'S COLLEGE HOSPITAL.—Operations, 1½ p.m.
ROYAL FREE HOSPITAL.—Operations, 1½ p.m.
CHARING-CROSS HOSPITAL.—Operations, 2 p.m.

ADVANCED PAYMENTS.

SUBSCRIBERS are reminded that their subscriptions in all cases must be paid within two months of the date of the order to secure the advantage of the lower rate of £1 1s. 8d. per annum, and that any subscription delayed beyond that period will be charged on the credit scale of £1 2s. 6d. per annum.

MEDICAL APPOINTMENTS.

ENGLISH.

BRACEY, W. A., M.R.C.S. Eng., has been appointed Surgeon to the Birmingham and Midland Eye Hospital.
DIVERS, Professor E., from Queen's Hospital, Birmingham, has been appointed to the Chair of Natural Philosophy at Charing Cross Hospital.
DOLMAGE, Inspector-General, has been appointed Consulting Surgeon to the Fimlico and Westminster Institute for Diseases of Women and Children.
MORRIS, J. C., L.F.P.S. Glasg., has been appointed Assistant Medical Officer at the North Wales Counties Lunatic Asylum, Denbigh.
MUCKLOW, Mr. T. C., has been appointed Assistant Dispenser at the Queen's Hospital, Birmingham.
OWEN, Mr. WILLIAM B., has been appointed Surgeon to the Clergy Orphan School, St. John's-wood.
SIS, Dr. MARIO, has been appointed Consulting Surgeon-Accoucheur to the Fimlico and Westminster Institute for Diseases of Women and Children.
THOMASON, R., M.R.C.S. Eng., has been elected Visiting Surgeon to the Hereford Dispensary.
ULE, ALEXANDER, F.R.C.S. Eng., has been appointed Consulting Surgeon to the London Infirmary for Epilepsy and Paralysis.

IRISH.

BUDDS, W. T., L.R.C.S.I., has been appointed Apothecary and House Surgeon to the Cork South Charitable Infirmary and County Hospital.
CRAWFORD, W., M.D., has been appointed to the commission of the peace for the county of Waterford.

POOR-LAW MEDICAL SERVICE.—VACANCIES.

Builth Union.—The Abergwessin District; area 68,480; population 3784; salary £42 per annum.
Carlisle Union.—Stanwin District; area 11,730; population 11,677; salary £50 per annum.
Tonbridge Union.—Third District; area 3184; population 1158; salary per annum: the Fifth District; area 4498; population 1411; salary £30 per annum: and the Workhouse, salary £80 per annum.

Births, Deaths, and Marriages.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

CLARENCE.—On February 2, at Aller Cottage, D'Urbans, Natal, the wife of Hyde Clarence, M.D., of a son.
DUNLOP.—On the 29th inst., at Holywood, County Down, the wife of Archibald Dunlop, Esq., M.D., of a son.
ELLIOTT.—On March 21, at North-street, Chichester, the wife of George H. Elliott, M.R.C.S.E., of a son.
GORINGE.—On February 24, at Colaba, Bombay, the wife of Dr. Goringe, 4th Royals, of a son.
GRACE.—On March 10, at Chipping Sodbury, Gloucestershire, the wife of A. Grace, M.R.C.S. Eng., of a son.
RYAN.—On March 17, at Upper Leeson-street, Dublin, the wife of M. Ryan, M.D., of a son.
SMYLY.—On the 28th inst., at 8, Mervin-square, North, the wife of Philip Crampton Smyly, Esq., M.D., of a son.
WALKER.—On March 2, at Walsingham, the wife of W. Walker, M.D., of a son.
WOODS.—McCausland.—On March 8, at Birr, Thomas Woods, M.D., to Charlotte Anne, daughter of the Rev. Mr. McCausland.
BOLTON—ORPEN.—On March 27, at Queenstown Church, by the Rev. John Lombard, A.M., Abraham Irwin Bolton, M.B., Assistant-surgeon, R.N., son of the Rev. Lyndon H. Bolton, Rector of Drumconrath, county Meath, to Geraldine Frances, third daughter of the late T. Hungerford Orpen, Esq., M.D., Queenstown.
ARNOLD, J., L.R.C.P. Edin., of Liverpool, on March 10.
ASBURY, BENSON V., M.R.C.S. Eng., at Enfield-highway, on March 20, aged 44.
ATKINSON, T. P., M.R.C.S. Eng., at Kilham, near Driffeld, on March 17, aged 51.
BLACKMORE, EDWARD, M.D., at Nelson, New Zealand, on December 6, aged 66.
BOARD, WALTER, M.R.C.S. Eng., at the Rectory, Burnham, on March 9, aged 55.
BULEN, DENIS B., M.D., at Ashton Lawn, Cork, on March 21, aged 64.
CRABBE, BENJAMIN, Surgeon, R.N., at Strabane, county Tyrone, on March 18, aged 32.
DAVIDO, M., L.R.C.S. Edin., at Clonmellon, county Westmeath, on March 14, aged 40.
DODGSON, THOMAS, M.D., at Skipton, Yorkshire, recently, aged 75.
FAIRBAIRN, WILLIAM H., Surgeon-Major H.M. Army, at 33, Jermyn-street, S.W., on March 23, aged 48.
GALTON, ROBERT C., M.D., at Hadzor, Worcestershire, on March 22, aged 35.
HALL, DAVID J., M.D., at Eastbourne, on March 23, aged 61.
HASTINGS, at Worcester, aged 75, Dame Hannah Hastings, wife of Sir Charles Hastings, M.D., D.C.L., on March 21.
MITCHELSON, WILLIAM, late Staff-Surgeon E.I.C., at 27, Castle-street, Dumfries, on March 23, aged 68.
PARKER, JOHN, M.R.C.S.E., at Wineanton, Somerset, on March 24, aged 59.

LECTURES

ON THE

NATURE, CAUSES, AND TREATMENT OF DYSPEPSIA.

Delivered at the Queen's Hospital, Birmingham,

By **BALTHAZAR W. FOSTER, M.D., F.L.S.**,

MEMBER OF THE ROYAL COLLEGE OF PHYSICIANS, LONDON; LICENTIATE OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND; PHYSICIAN TO THE QUEEN'S HOSPITAL, AND PROFESSOR OF CLINICAL MEDICINE IN QUEEN'S COLLEGE, AND OF THERAPEUTICS AND MATERIA MEDICA IN SYDENHAM COLLEGE, BIRMINGHAM; PHYSICIAN TO THE GENERAL DISPENSARY, BIRMINGHAM.

LECTURE IV.

(Continued from page 272.)

II. THE researches of modern physiologists have done much to render our knowledge of the *gastric* stage of digestion more perfect and precise, and in our limited consideration of the functions of the stomach, we shall freely avail ourselves of the results of their labours. The determination of the value of the saliva as a transforming agent and the elucidation of its special action on starch, cleared the way for more correct notions of the action of the gastric fluids. In the oral stage of digestion we have seen the food reduced to a state of minute sub-division, some portions of it more or less changed, but all prepared for the operation of the more active fluids of the stomach and intestines. In the mouth, however, we have not recognized a portion of the alimentary tract in which the absorption of aliment takes place. In the stomach we first distinctly meet with the process of absorption, but here only to a limited extent. Water, alcohol, and some of the materials rendered soluble by its secretions, are we know taken up by its numerous bloodvessels; but this absorption is very different from that which occurs in the small intestine. The great distinguishing character of gastric digestion is the chemical change produced in certain forms of nutriment. This action is chiefly devoted to the conversion of the azotised or albuminous portions of our food into a condition fit for absorption, and possibly further elaboration in the intestinal tract. The oleaginous and starchy matters are but slightly affected by the gastric juice; cell walls are dissolved by its action, and their contents, fat or starch, set free. The secretion of the stomach fluids forms the *vital* part of the process; the *chemical* part consists in the action of these fluids on the food; and a *mechanical* part is added in the movements of the stomach.

These movements have been well studied by Dr. Beaumont in the case of Alexis St. Martin. "They," he observes, "not only produce a constant disturbance or churning of the contents of the stomach, but they compel them at the same time to revolve about the interior from point to point, and from one extremity to the other." The cavity of the stomach during its empty state is, by the contraction of the muscular fasciculi of its walls, rendered very small, and on the entry of food the parietes tend to press upon the alimentary mass. The contraction of each muscular band now, however, alternates with relaxation, and thus a very varied movement is produced. This peristalsis has the effect of making the contents of the cavity circulate through its interior in a definite manner, as has been pointed out by Dr. Brinton. The bolus entering by the œsophagus, passes along either the greater or lesser curvature of the stomach, and on reaching the pylorus enters a *central* or return current, to be carried back to the œsophageal opening, and thence a second time

along either curve. We have thus a constant circulation kept up by these central and peripheral currents, the circuit of the stomach occupying about three minutes, but as the solution of the food advances the motion becomes quicker. Towards the end of digestion a constriction or kind of hour-glass contraction of the stomach occurs, by which the pyloric extremity is separated from the rest of the cavity. This contraction is the result of the action of the transverse muscular fasciculi, and assists in the expulsion into the duodenum of the digested portions of the food. In addition to the motions above described, we may add that there is a continual agitation of the stomach and its contents by the respiratory act. These movements are very important to the due performance of digestion, for by the churning motion the food in its circulation is continually brought into contact with fresh portions of the mucous membrane, and thus thoroughly submitted to the action of the gastric juice. The expulsion into the duodenum of the digested contents is also gradually effected, and we may add that we doubt not that the secretion of the gastric juice itself is materially favoured by these muscular contractions, as that of saliva is by mastication. The pneumogastric nerves are now generally supposed to preside over the muscular coat of the stomach. We can readily understand how an excess or defect of these movements may produce much disturbance. Excessive action, by driving food into the intestinal canal, before its thorough transformation has taken place, not only deprives the system of a great portion of the nutritive value of the ingesta, but also passes into the duodenum undigested matters, and more especially unused gastric juice, to trouble and obstruct its functions. Atony of the muscular coat of the stomach (a condition more commonly recognized), on the other hand by not favouring the free flow of the gastric juice, and by not thoroughly submitting each particle of the food to the secretion, is a frequent cause of dyspepsia. As these conditions are transitory or persistent in their character, accidental or chronic indigestions supervene.

The gastric juice, on which the digestive power of the stomach depends, is a clear limpid fluid, colourless or nearly so, and very slightly viscous. It contains but little solid matter, is always acid in its reaction, and holds in solution a peculiar ferment called *Pepsin*. The analysis of this fluid has excited much attention for a very long period, and is still a subject of dispute. The want of harmony in the results of many able observers may be traced most probably to the different conditions under which the fluid was collected by them. The nature of the acid to which its constant acidity is due has been the chief point of difference, and even at this day there is some difficulty in deciding between the conflicting claims of the Lactic and Hydrochloric acids. We have the high authority of Professor Graham in favour of the latter, and his opinion is also supported by many able observers.* Lactic acid, although constantly found in the stomach, owes its formation, doubtless, to the prolonged action of the salivary diastase on the starch of our food—an action which we have seen usually continues in the stomach.

The Pepsin or *organic ferment* which is the other essential constituent of the gastric juice—for neutralize the acid, or precipitate the pepsin, and you destroy the activity of the secretion—is a peculiar grey substance secreted by the stomach-cells. It is soluble in water, and is by many supposed to be secreted in combination with the acid. The researches of Brücke have disproved this, for he has obtained pepsin neutral from the stomach-cells, and it appears from his experiments that only on its secretion does it unite with the acid. These observations suggest the view that the pepsin and acid are formed separately, and that the latter is poured forth by the mucous membrane generally, while the former is secreted by the stomach glands. Bernard was led to this conclusion by the following striking experiment:—He injected into the jugular vein of a rabbit a solution of lactate of iron, fol-

* Vide Carpenter, op cit, p. 81.

lowed by one of ferrocyanide of potassium; three-quarters of an hour afterwards the animal was killed, and there was found in the secretions and the tissues generally no blue coloration, although the two injected salts could be detected. The alkalinity of the blood had prevented the combination of the injected substances, which combined, however, and gave a blue colour on the addition of a drop of acid to any part. On opening the stomach the *gastric follicles were unstained*, showing that they contained no acid; the *mucous membrane*, on the other hand, was *discoloured*.* These two constituents, the hydrochloric acid and the pepsin, exert upon the azotised portion of our food great transforming power. We must remember, however, that these secretions do not continually exist in the stomach, but are only poured forth on the stimulus of the ingesta. During fasting the mucous membrane is coated by another secretion:—the gastric mucus, alkaline in its reaction, and only protective in its quality. The quantity of gastric juice secreted during the twenty-four hours has been variously estimated at from 1-20th to 1-10th of the body weight. These calculations are of little value to us; but the fact that the formation of this secretion has the closest relation to the requirements of the system is most important; and we should ever bear in mind, that only a definite amount of aliment can be converted in a given quantity of the fluid, and that any excess of nutriment beyond that saturated by the gastric secretion becomes a source of digestive difficulty.

You naturally inquire, on what changes in the albuminous portion of our food does gastric digestion depend? Fortunately recent inquiries have done much to enable us to answer this question, and to place before you facts that may be applicable in the treatment of disease. The operation is, as I have said, a species of chemical solution, limited to azotised substances. According to the careful researches of Meissner and others,* the gastric juice forms, from whatever variety of albuminous material submitted to it, two new compounds—*Peptone* and *Parapeptone*. Neither of these is, like the original albumen, precipitable by heat. The peptone is formed in much the larger proportion, and the parapeptone may be thrown down from the solution by neutralizing it with an alkali. Parapeptone is insoluble in water, but is soluble in slightly acid or alkaline fluids. Peptone is soluble in water, but is precipitated by alcohol, tannic acid, and corrosive sublimate.

Gelatinous tissues are reduced in a somewhat similar way, and thus, like the albuminous substances, are rendered more diffusible. Professor Graham has pointed out that albumen has a low diffusive power, and a very high endosmotic equivalent, and the changes spoken of above have, doubtless, for their chief object, the mutation of this property and the promotion of the absorption of the compound.

As albumen and not peptone and parapeptone (most probably converted into peptone in the duodenum) is found in the fluids of the body, these substances are most probably again reconverted by the intervention of the liver, and thus rendered fit for nutrition. The operation of the gastric juice in reducing the food submitted to its action into a homogeneous fluid, chyme, bears a strong resemblance in many ways to the effect produced by a high temperature and strong oxidation. Prolonged boiling and exposure to the action of ozone produce the above-described conversion of albumen. This fact is noteworthy as possibly containing matter for therapeutical application. The changes above described as being produced in the oleaginous and starchy matters submitted to the action of the stomach are also effected by the agency of heat.

The derangements of the functions of the stomach, considered with reference to the gastric juice, may be

stated to be those depending either on *modifications in the quality or alterations in the quantity* of this secretion. We must remember, however, that these abnormalities may affect either or both of its essential constituents.

The *quality* of the digestive fluid may err by containing too little of the acid principle, or the normal amount of the acid having been secreted, the addition of some foreign element, as we see occurring in uræmia, may neutralize it. Any excess of acid is also injurious, for we learn from the valuable experiments of Brücke* that a weakly acid gastric juice (containing 0·1 per cent. of acid) digested fibrin most rapidly, and that a somewhat stronger fluid (containing 0·2 per cent. of acid) was most potent in the conversion of coagulated albumen. The same series of experiments have taught us that in proportion to the increase of the acidity above these quantities the period required for digestion was prolonged.

We also gain from these facts this useful knowledge for therapeutical application, that in feeble states of the stomach the administration of gluten is preferable to the use of animal albumen, and that the employment of uncooked meat, so eminently useful in certain states, is founded on physiological truth.

There are many modifications in the quality of the gastric juice, especially of the pepsin, of which we are at present most profoundly ignorant, and to which many of the dyspepsias coming under our notice are no doubt due. Advances in animal chemistry will in time, most probably, enable us to fathom these chemical errors, and at the same time place our treatment of them on a more scientific basis.

A *diminished secretion* of gastric juice is frequently met with in anæmia and chlorosis, and is often associated in such cases with an increased secretion of mucus. In persons accustomed to stimulate the stomach by the free use of condiments and alcohol, the quantity of gastric juice is, after a time, much lessened. The ordinary stimulus no longer promotes its flow, and unless some more powerful irritant be made use of, but little fluid is poured out. An increased formation of mucus occurs in these cases also, and by virtue of its alkaline reaction, it of itself necessitates the freer production of the true digestive fluid. In the old a deficiency in its quantity is a frequent cause of dyspepsia, and is owing in many cases no doubt to degenerations in the glandular apparatus; in others, it may be to diminished excitability in the nerves presiding over the function.

Whenever the digestive fluid is defective in quantity, or in its transforming power, the food long delayed in the gastric cavity proves a source of local irritation, and passes into the duodenum unprepared for the action of the intestinal juices, to embarrass the third stage of digestion, and by decomposition to cause intestinal dyspepsia. The *excessive formation* of gastric juice is met with in many cases of stomach disorder of a sympathetic nature; in other instances the excess is chiefly seen in relation to the ingesta. Whence it results (unless the fluid is expelled by vomiting) that fermentative changes in the food arise during stomach digestion, and the passage of the too acid chyme into the duodenum proves a fertile source of digestive trouble.

Experimental inquiry has not yet determined for us satisfactorily the nerves which preside over the secretion of the fluids under consideration. The pneumogastric and sympathetic nerves probably each play a part, and to their neuroses, doubtless, many of the modifications of the fluids may be referred. The influence of mental emotion in checking the digestive act, as we have already seen, strongly points to the nerves supplying the stomach as possessing much power in modifying its secretions. The admixture *with the gastric juice of various fluids* chemically antagonistic, I need hardly tell you, checks its transforming effect upon our food. The regurgitation of bile and pancreatic fluid and a too free passage of saliva into the stomach occasionally produce indigestion in this way.

MERCER'S HOSPITAL.

CLINICAL LECTURE.

PARALYSIS AFTER DIPHTHERIA.

By WILLIAM MOORE, M.D. Dub., M.R.I.A.,

PHYSICIAN TO MERCER'S HOSPITAL; PHYSICIAN-IN-ORDINARY TO SIR P. DUN'S HOSPITAL AND TO THE INSTITUTION FOR THE DISEASES OF CHILDREN; LECTURER ON PRACTICE OF MEDICINE AND ON CLINICAL MEDICINE, ETC.

GENTLEMEN,—Numerous opportunities have been afforded you during the past session of seeing paralysis in its various phases in the wards of this hospital; but as the following case presents some features of more than ordinary interest, I have thought it expedient that we should examine it in detail on the present occasion. The history of this patient, which has been carefully collected for us by Mr. Henry G. Thompson, is as follows:—Martha L., aged 16, was admitted into Hume's ward on the 20th of March last; her appearance at that date was anæmic and dejected for a girl of her age, and on being asked a question she seemed stupid, and in most instances it had to be repeated before we could obtain an answer. She told us that up till two months before her admission she was a strong healthy girl; she then got a sore throat, as she described it, which lasted over a month. About a week after recovering from this, she was seized with the paralytic phenomena which I shall detail to you, and of course was unable to attend to her ordinary duties.

In the first place, we were struck not so much with her partial loss of voice, as with its "nasal" character, which resembled that met with in persons who have lost their palate; however, a glance sufficed to show us that there was no such solution of continuity to account for it, nor did the throat generally look unhealthy, as far as we could see. However, the impunity with which she allowed the examination to be made led us to observe still more closely, when we found there was complete anæsthesia of the velum, uvula, and arches of the palate, so much so, that she was not conscious of our touching them with the point of a pen, and on pricking her tongue, although she felt it, still she did not complain of it paining her in the least. This partial loss of sensation seemed better marked over the left half of the tongue and towards its base. Taste was impaired, as also was smell, but her hearing seemed unaffected. She complained of a peculiar tingling sensation in her lips, which felt, at times, as if they were asleep, and when she attempted to swallow, particularly solids, they felt as if they stuck at the top of the pharynx. In short, she was only able to get over fluids, which occasionally came back through the nares. There was dilatation of both pupils, especially the right, and her eyesight was so far affected as to prevent her reading. She described a sense of creeping over her fingers and the palms of her hands, which extended up as far as her elbows, and this same sensation she also felt in the lower extremities, as far up as her knees. Over these parts there was no loss of sensation; on the contrary, the muscles were rather flabby, and painful on being handled. She also complained of pain along the course of the spine generally, but especially in the cervico-dorsal region, and when walking she could not hold herself erect, and seemed semi-paraplegic. The menstrual discharge has not re-appeared since her first illness, and the urine is alkaline, sp. gr. 1025, and contains albumen.

Now, I think this case presents some points of unusual interest. As we did not see the "sore throat" this girl suffered from in the first instance, we cannot absolutely pronounce it "diphtheritic," but the rational inference, from the history we got of it, is, that it was of that family. Under any circumstances it was the commencement of this girl's ailment, for as her aunt has told us, before she got the sore throat, "she was healthy and active."

The character of this paralysis is progressive; in the

first place, a week elapsed between the time of the patient's apparent recovery from the sore throat and the appearance of the paralysis; then the muscles of the pharynx became affected, afterwards those of the tongue, lips, eyes, and upper extremities, the lower extremities being the last engaged. The anæsthesia of the fauces was most marked, but this is the rule in such cases, the glosso-pharyngeal muscles being so far paralyzed as to give rise to some alarm when the patient attempted to swallow anything solid. But although you saw such well-defined paralysis, both of sensation and motion, of the faucial and pharyngeal muscles, still there was no evidence of the larynx being implicated (which, *cæteris paribus*, is a still more grave affection). She has no cough, and the alteration in her voice is not of the aphonic or metallic character met with in laryngeal disease. No, the voice is essentially "nasal," from the paralytic condition of the uvula interrupting its natural exit.

We next have evidence of the gustatory and olfactory nerves being blunted, in the deterioration of the taste and smell, and the sluggish dilated pupils, with imperfection of vision, indicate that the ciliary nerves have been "hit," so to speak. There is no well-defined paralysis of the upper extremities, but the patient suffers from a sense of formication and numbness in the fingers, palms of the hands and forearms, and you may observe the muscles are soft and painful on being handled; the lower extremities are cold and weak, the muscles are flabby, and when she came into hospital she had comparatively little use of them, the sense of "pricking" or "tingling" being felt as far up as the knees, more especially when she tried to walk. When we turn to the internal functions, we find loss of nervous influence of the pelvic viscera, evidenced in the arrest of the menstrual function and in deficient action of the bladder, the urine being below the normal quantity, having an alkaline reaction and containing albumen; the specific gravity, as I have already mentioned, being 1025—a circumstance I wish you to bear in mind.

Now, although the presence of albumen in the urine in these cases is the rule, and whilst it is an index of the gravity of the disease we have to deal with, still you must not conclude that it involves a uræmic condition of the system; on the contrary, it has been found at the very acme of the affection, when the urine was intensely albuminous, that the quantity of urea excreted in a period of twenty-four hours was about twice as great as that excreted during a similar period when convalescence was established, while the amount of chlorides was also nearly doubled. Under any circumstances, in the case of Lindesay, we have no symptoms of uræmic poisoning, although we have a copious deposit of albumen in the urine; on the contrary, the specific gravity of the urine (1025) alone would almost enable us to say that at least between 300 and 400 grains of urea were excreted in twenty-four hours. I believe I am safe in stating that there is no acute disease more frequently followed by paralytic symptoms than this diphtheritic or croupy throat. Rogers found in 210 cases of diphtheria, which occurred in the Hôpital des Enfants, that paralytic symptoms followed in thirty-one cases, and he concluded that the proportion would have been one-third or one-fourth more but for the removal of some cases and the death of others. The question naturally arises—Under what special type should this form of paralysis be classed? This is a question not easily answered; I am inclined to regard it as a peripheral nervous lesion in the first instance, which, being conveyed from the parts primarily affected (in this case the pharyngeal nerves) to the cerebro-spinal system, results in reflex paralysis.

And now, gentlemen, as regards the prognosis of such cases, provided there is no evidence of pulmonary or cardiac paralysis, I should call it "favourable," and neither of these phases, I am happy to say, exist in the case before us.

With respect to the treatment of this form of paralysis tonics, as iron, nitrate of silver, sulphurous remedies, and

electricity, have been generally recommended. But I will recapitulate for you what our patient has been taking since her admission—viz., one-twentieth of a grain of strychnine, with one grain and a half of sulphate of iron three times a day. A liniment of compound camphor, with chloroform, is applied daily along the spine, and we purpose to superadd electricity. Her diet is liberal, good beef-tea, and four ounces of wine. She has now been twelve days under this treatment, with the following results: she can hold herself erect, and walk without drag or ataxy; her eyesight is so far improved that she can read for her amusement; the senses of smell and taste are returning; the albumen is gradually disappearing from the urine; in fine, all the paralytic phenomena, with the exception of difficulty of deglutition, are steadily vanishing; and I do not despair of this yielding to our treatment within a reasonable time.

CLINICAL RECORDS

ILLUSTRATIVE OF THE DISEASES OF CHILDREN.

By G. STEVENSON SMITH, L.R.C.S.Ed,

FELLOW OF THE OBSTETRICAL SOCIETY, AND FORMERLY RESIDENT MEDICAL OFFICER, ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN.

IV.

TYPHOID FEVER: WITH CASES, AND POST-MORTEM APPEARANCES.

THE diagnosis of typhoid fever in young children is often a matter of extreme difficulty, for unless the distinctive rose-coloured spots make their appearance, we cannot rely upon any other symptom as being conclusively pathognomonic. Neither the tenderness of the belly alone, nor the gurgling in the right iliac fossa, nor the diarrhœa, nor the tongue affords any certain or reliable information as to the particular kind of fever we have to deal with. No doubt the association of all these symptoms in a child suffering from fever would be sufficient to lead us to conclude that the disease was enteric; but then it is comparatively rare to find them all present in a complete group, and not unfrequently a patient passes through all the stages of typhoid fever without ever showing more than one or two of the signs we have enumerated. It is a prevalent idea that in doubtful cases the occurrence of diarrhœa is distinctive of the typhoid character of the fever, but nothing can be more fallacious; for we have seen many instances of that disease in children, in whom from the beginning of the disease till convalescence was established there never was any looseness of the bowels at all.

Then, as to the gurgling in the right iliac region, we remember how a distinguished French physician, lately deceased, was accustomed to point out to his pupils at La Charité the great importance of this sign in the diagnosis of enteric fever. But during the late epidemic of typhus in this city, we have over and over again detected both gurgling and tenderness on the right side of the belly in patients whose skin was mottled all over with the mulberry rash. The fact of the tenderness having been confined to one side shows that it was not merely a part of the general hyperæsthesia usually so well marked in the typhus of early life.

The daily observation of the temperature of the body promises to be of some assistance in the recognition of the various febrile diseases; but unfortunately the range of temperature in the early stages of typhus and typhoid fevers is not so markedly different as to yield any very precise information.

It is only, therefore, by a very careful study of all the features of each particular case, that the true nature of the fever can be correctly diagnosed, and it ought to be remembered that the appearance of the rose-coloured spots,

which generally come out at the beginning of the second week, is the only sign which, by itself, affords positive proof of the presence of typhoid fever. The sparseness of the eruption, and its absence from the face and hands, will generally be sufficient to distinguish it from the rash of typhus, which, in the early stages, presents no great difference in colour from the rose spots of typhoid.

The characters of enteric fever seem to vary as much in different epidemics as do those of typhus or scarlet fever. Thus in an epidemic which prevailed a few years ago amongst young people in a country district in Scotland, a large number of the patients who came under my care had hæmorrhage, sometimes to an alarming extent, from the mucous membrane of the nose, mouth, stomach, or bowels, whereas in the Edinburgh Children's Hospital such an occurrence is very rare. Indeed, during the period of my residence there as House-Surgeon, in only one case of typhoid fever was there a discharge of blood, whilst amongst the typhus patients epistaxis was frequently observed.

In the case just alluded to there was a considerable quantity of blood passed from the bowels on several occasions, and this was followed by a crop of purpura spots on the abdomen and thighs.

In enteric fever the period of convalescence is usually much more protracted and irregular than in typhus, and children who have suffered from it frequently continue in a state of great mental and bodily weakness for many weeks.

Treatment.—The treatment of typhoid and other forms of continued fever, as practised at the Children's Hospital, is, as a rule, extremely simple. Every patient gets a mixture of acid hydrochloric diluti, simple syrup, and water, according to this prescription:—

℞ Acidi hydrochlor. dil. ℥i.
Syrupi simp. ℥i.
Aquæ ad. ℥iii. M.

Sg. A dessertspoonful every four hours. Occasionally, if a stimulant is indicated, a drachm of the spt. eth. nit. is added. This mixture is very pleasant to the taste, and possesses tonic and refrigerant properties; besides it is easily taken, and indeed often greedily demanded by very young children. It was Dr. Chambers, of London, we think, who first introduced the practice of giving acids in fever.

If diarrhœa exists then nothing will be found more useful than the administration of a few grains of Dover's powder, which, besides allaying the irritability of the bowels, also soothes and comforts the patient. In cases where the looseness is very persistent, it will be necessary to combine with the Dover's powder a grain or half a grain of the acetate of lead. When hæmorrhage occurs enemata of starch and laudanum will be found to be of much benefit but occasionally more active remedies are required. The nitrate of silver given in quarter or half-grain doses, along with some preparation of opium, is often attended with much benefit. It is usually prescribed in the form of pill to adults, but in young children it may be given in solution:—

℞ Pulv. argenti nit. gr. iii.—gr. vi.
Mucilaginis,
Syrupi simp. aa. ℥ss.
Aquæ distill. ad. ℥iii. M.

Sg. A dessertspoonful when necessary.

In one case which was under my care in private practice, the hæmorrhage, which poured forth in large quantities from the stomach and bowels, was only arrested by the administration of small lumps of ice.

When the breath and the evacuations smell badly, the chlorate of potass dissolved in milk or water and given as a drink acts very beneficially.

If there is much tenderness of the belly warm light poultices of linseed meal or turpentine stupes are useful in allaying the pain, while an enema of castor-oil and a few drops of the tincture of asafœtida will be of use in re-

moving the tympanitis, which frequently proves very troublesome and distressing to the patient.

The body should be sponged with vinegar and tepid water at least once a day, as it promotes the action of the skin, and is both agreeable and refreshing.

With regard to the very important subject of diet, we have merely to say that the patients are allowed sweet milk *ad libitum*, with small quantities of beef-tea occasionally, and this is all the food that is necessary. During convalescence, however, eggs are sometimes given, generally beat up in the form of flip. Solid food, such as beef, &c., is often productive of much evil by being given too soon, and is a frequent cause of diarrhoea and feverishness. As to the use of wine and brandy, that is a subject which has caused a great deal of discussion, and concerning which much diversity of opinion still prevails amongst practitioners. Our experience leads us to take up no extreme position either on one side or the other; for while we hold that stimulants are often used much too freely and to the injury of the patient, we must at the same time admit that we have seen typhoid patients saved by the continuous and judicious administration of brandy. The fact is that many cases will do well without a single drop of wine, while others need to be stimulated from the very first. There are some physicians who in every case of fever pour into the patient so great a quantity of wine or brandy that the symptoms are rendered most complex and confused; while others again, even when the patient's powers are flagging, when the tongue is black, and the teeth are covered with sordes, refuse to allow the administration of any stimulant whatever. The exercise of a wise discrimination on the part of the practitioner is therefore required to prevent his falling into error. If the diarrhoea is troublesome, sound port wine will be the most suitable, but in many cases light dry sherry is preferred by the patient. When there is much nervous prostration, indicated by tremor of the tongue and hands, brandy ought to be given.

The following cases illustrate the nature, course, and pathological appearances of typhoid fever as occurring amongst children:—

Case 1.—Severe attack, diarrhoea, albuminous urine—no rash—protracted convalescence.—M. S., aged 12. Ill about eight days, having been seized at first with headache, vomiting, looseness of the bowels, and tenderness of belly. When first seen by me on August 22, 1865, the skin was dry and dusky; eyes suffused and wild like; belly tympanitic and tender on pressure; gurgling in right iliac fossa; tongue coated with a yellowish white fur, but red at the tip and margins; pulse 120; a warm bath was given; Dover's powder was prescribed, and a turpentine stupe was applied to the belly.

August 23rd: The stools are still loose, and of a light yellow, pea-soup colour and consistence; still complains of belly; urine is slightly albuminous, and of sp. gr. 1017. A mixture containing the dilute muriatic acid was prescribed (see formula given above). No rose-coloured spots can be detected; pulse 110. Takes beef-tea and milk freely. Dover's powder to be continued if bowels are loose.

24th: Belly still tender and tympanitic; no rash. Tongue loaded at back part, but red at tip; breath offensive; pulse 100.

Towards the evening patient got much worse. The bowels were frequently moved, the stools being passed in bed. She was restless, and kept moving her head about unceasingly. Tongue brown; pulse 130, and feeble. A teaspoonful of wine was ordered every two hours; small doses of the acetate of lead were added to the Dover's powder, and enemata of starch and laudanum to be given.

25th: Has slept little; but the diarrhoea is checked; pulse quick and very compressible; great thirst. The wine to be given every hour. In the evening patient began to chatter incoherently, and moan heavily. Brandy substituted for the wine. A draught of sol. morph. mur. and vini antimon. was given. Linseed-meal poultices applied to belly.

26th: Great prostration; breathing shallow, and stupor considerable. The aromatic spt. of ammon. and spt. of lavender to be given along with the brandy every hour. Got rather better towards night, and had a refreshing sleep. On the 28th she began to vomit the milk, but retained beef-tea. The urine continued slightly albuminous; tenderness of belly diminished; tongue moist and clean at tip; pulse down to about 90, but very weak. Brandy to be given in dessertspoonful doses every four hours. Still very restless, and her speech is very indistinct. Bowels natural. On September 3rd a bed sore formed over the sacrum, and caused her a good deal of annoyance. Stupor continues, and she is very deaf.

September 5th: Liquid greenish matter trickles away from the bowels, and sometimes mixed with it are some dark flakes resembling tealeaves. Enemata of plain water ordered. There are some pustules and petechiae on legs. Quinine was prescribed. Fever quite away, but the intellect is very dull.

In this childish and feeble condition she remained till about the beginning of the month of November, when she began to gather strength. She then rapidly improved both in mental vigour and bodily strength, and by the 15th she was quite better.

Case 2.—Severe Attack.—Copious eruption of rose-coloured spots.—Very little diarrhoea.—M. C., et. 9, was seized on the 22nd February, 1866, with shiverings and other febrile symptoms. When first seen on February 27th, the tongue was loaded, rough and claggy on the dorsum, with margins red. There was gurgling in right iliac region, and a little pain on deep pressure; pulse 132; respiration 40; temperature in axilla 102 2-5° Fahr. The muriatic acid mixture was prescribed. On the 2nd of March one or two spots were observed on the belly, of a pink or rose-coloured hue. Bowels rather loose, but not often moved. Eyes suffused; vomiting her beef-tea. To have Dover's powder at bedtime.

March 3rd: More rose-coloured spots to-day on body. Tongue raw and fissured horizontally. The spots continued to come out in successive crops till the 5th, after which no more appeared. They remained out for about a week, and then gradually became fainter, and finally disappeared. She got very deaf and stupid about the 7th of March, and the tongue was then red and raw, and covered on its tip with numerous minute elevations, resembling sudamina. The pulse was 120, and the heat of the body 103 1-5° Fahr. After this, patient went on well till the 14th, when she had severe rigors, got blue in the face, and much prostrated. Mucous rales were heard over the chest, but there was no effusion. Warm drinks were given, and port wine negus, which had the effect of restoring her. During the continuance of these rigors, which came on about the same hour on three successive mornings, the thermometer placed in the axilla stood at the very low figure of 96, 95, and on one morning at 94 degrees; and rose again in the evening 8, 9, and on one occasion 10 degrees above the morning temperature. After this she rapidly improved, and made a good recovery.

Case 3.—Typhoid fever proving fatal about the 12th day. Post-mortem appearances.—M. S., et. 4, had been ill about six days, but had only been confined to bed for three days, with headache and pain in the belly. On the 16th of January, 1866, the tongue was coated and very rough on the dorsum, and had the appearance and colour of a piece of tripe. There was also a dry streak of a reddish colour down its centre. The face was flushed, eyes suffused, lips parched. No tenderness of belly and no gurgling. A brother of hers had died from cancerum oris about two weeks previously, and the house they lived in was in one of the worst localities of the city, being dark, damp, and badly ventilated. The muriatic acid mixture was prescribed along with chlorate of potass as a drink. The pulse was 132; respirations 36 in the minute; temperature, 104 2-5° Fahr. On the 17th a few dusky-looking spots were observed on the sides of the thorax and belly, but

it was difficult to say whether they were really true typhoid spots. She was restless, and often started up in bed crying for her mother. On the 19th the pulse was about 140 and weak, and she was ordered to have a dessertspoonful of wine every three hours. The belly was distended and tympanitic, but was not at all tender on pressure. The bowels were now loose, the stools having a pale greenish-yellow colour. Dover's powder and acetate of lead were prescribed, four grains of the former and one of the latter to be given every two hours till the diarrhoea was checked. Lime water was also administered amongst milk. This treatment sufficed to stop the bowel complaint, but she suddenly on the morning of the 21st became livid in the face, the breathing was short and gasping, the eyes swollen, pupils contracted, pulse 170 and very feeble; temperature in the axilla, 104 1-5°. Some dulness on percussion was detected over the left lung posteriorly, but patient was so extremely exhausted that no minute or satisfactory examination of the chest could be made. She was quite sensible, and answered any question that was put to her. She got gradually weaker, however, and died at seven p.m. Just before death a considerable quantity of bloody fluid escaped from the mouth and nose, while at the same time a quantity of liquid fecal matter was discharged from the bowels. Two hours before death I found the heat of the body to be 104 2-5°.

Secio twenty hours after death.—Rigor mortis well marked. Hypostatic congestion extensive. The left lung was engorged at its base, and there was a small quantity of clear fluid in the left pleura cavity. Right lung natural. The pericardium was distended, and contained about an ounce and a half of straw-coloured fluid, but the heart itself was natural. Liver slightly enlarged. Spleen large and pulpy, its capsule having a shrivelled appearance. There was a little clear fluid in the cavity of the peritoneum. The left kidney was larger than the right, but both appeared to be healthy. Along the course of the small intestine there were pinky spots on the surface of the bowel. On opening the bowels Peyer's patches were seen to be raised and prominent, of a greyish colour, and roughened on their surface. At the situation of the glands the bowel had a bright pink appearance. This prominence and roughness of the Peyerian patches was best marked, however, in the neighbourhood of the ilio-cæcal valve, where the gland structure projected about three lines above the surface of the mucous membrane. The glandular surface did not appear to be ulcerated, but when pressure was made by the finger upon it the rough portions broke down and were easily scraped away. The rectum was slightly inflamed, and the cæcum was of an unusually dark colour. A few small lumps of hardened faeces were washed out of the intestines, and that was all they contained.

The stomach, on being opened, was found to contain some grumous matter, and its lining membrane had several pinky patches on it. At the pyloric orifice a quantity of dirty-looking gelatinous mucus was adherent. The mesenteric glands were inflamed and slightly enlarged.

Case 4.—*In which death occurred about the twenty-fifth day.*—*Post-mortem appearances.*—J. W., æt. 10, when first seen by me on the 4th of August, 1866, had been ill for nine or ten days, her illness having commenced with rigors and headache. The skin was hot and dry, tongue loaded, but red at tip, eyes suffused, pulse small and quick. No eruption could be detected. The acidi muriatici diluti was prescribed, and the patient went on favourably till the 10th, when tenderness of the belly and diarrhoea came on, and the girl became very weak. Notwithstanding the free use of brandy and ammonia she gradually sank and died on the 19th of August, having complained of pain in the belly till the last.

Secio.—On opening the abdomen the bowels were seen to be much inflamed, and were glued together and to the peritoneum. In the pelvis a large quantity of curdy-like lymph was deposited, and surrounded the bladder to the depth of more than one inch. Near the ilio-cæcal valve

the glandular structures were found to be ulcerated, the ulcers being ragged and irregular in appearance. The spleen was very dark in colour, but not enlarged. The mesenteric glands were indurated, and much above the normal size.

Case 5.—*Hæmorrhage from nose and bowels—purpura—recovery.*—J. B., æt. 8. When seen on 22nd December, 1864, had quick pulse, tongue loaded with a yellowish fur, but red at tip and edges. There was headache and a good deal of tenderness on pressure over the right iliac region. Bowels rather loose. He was put upon the muriatic acid mixture. It was stated that patient had bled freely from the nose a few days before.

On the 28th patient was progressing favourably, the tongue was cleaning, bowels acting naturally, but he was very weak and tremulous, so that brandy was given, to the extent of four ounces in the twenty-four hours. On the 31st December he was not so well, and passed a large quantity of blood from the bowels. Some Dover's powder and gallic acid prescribed, but as this failed to check the hæmorrhage a mixture containing the nitrate of silver and tincture of opium was ordered. This had a beneficial effect, and, although extremely prostrated, patient passed no more blood, but gradually regained his strength. Convalescence was tedious, and during the course of it he had to be attended to with scrupulous care. It is worthy of notice that five days after the hæmorrhage from the bowels occurred a crop of purpura spots made their appearance on the abdomen, but soon disappeared again, under the use of the syrup of the phosphate of iron.

We have notes of many other cases, but these are sufficient to give some idea of the various symptoms and usual pathological lesions of enteric fever.

In Case 1, the urine was found to be slightly albuminous, but this is by no means rare in typhoid fever, and need not be regarded as a complication of any serious importance. The formation of a bed-sore is a much more troublesome thing to have to deal with, and, as in this case, it is frequently a source of much suffering to the patient, and entails upon the nurse a great amount of careful watching and attention. Fever patients have all a tendency to lie on the back, and care should be taken to move them every now and again on to the side, so that the skin and textures over the sacrum may not be too long subjected to pressure. From the constant diarrhoea which sometimes exists, the hips are apt to get chafed and irritable, so that the utmost attention should be paid to keeping the parts scrupulously dry and clean. It ought likewise to be kept in mind, that in a patient who has had a tedious convalescence, and may be greatly emaciated, such a trifling source of irritation as a wrinkle or a hard seam of the sheet may be sufficient to cause ulceration of the skin, and should therefore be avoided. For, although this may appear to be a small matter and unworthy of notice, it is nevertheless true, and prevention in the case of bed-sores is very much better than cure. In Case 1, there was no eruption, but the attack was, notwithstanding, a severe one, and for long the poor child was perfectly, stupid and could not even give expression to her wishes.

In the second case recorded there was a very copious eruption of the characteristic rose spots, more copious, indeed, than I ever before saw. The spots made their appearance just about the eighth day of the fever, on the sides of the abdomen, and continued to come out in successive crops till the twelfth day, after which no more were noticed. They remained quite distinct till about the twentieth day when they began to fade, losing their bright hue gradually, and finally disappearing altogether. The extraordinary fluctuations of the temperature, as ascertained by Aitkin's thermometer, which preceded convalescence, are worthy of remark. On one morning during a rigor the mercury stood at 94° Fahr., and rose again in the evening to 104°. This great fall of temperature indicated a need of stimulants and warm drinks, and the subsequent rise to 104° showed that great care was necessary during the course of convalescence. In the observa-

tions, which I have made on the temperature of the body during fever (see *Edin. Med. Journal* for March, 1866), I found that, as a rule, the heat of the body, as ascertained by placing the thermometer in the axilla, was always under the normal standard at some period during recovery; and this fact would seem to indicate the operation of the law of compensation; the heat during the continuance of the febrile state being so much above the natural range, and then, as if to counterbalance this falling for a time during convalescence to some degrees below the standard of health.

In Case 3, death took place about the twelfth day of the fever, and I would call attention to the fact, that a brother of this patient's died a fortnight previously from cancerum oris. Whether the horrible stench which was emitted from the gangrenous slough in his cheek had so poisoned the atmosphere of the small, badly ventilated house, as to induce fever in the person of his sister; or whether, as is most likely, he had also suffered from fever and was afterwards attacked with stomatitis, I could not accurately ascertain. Two hours before death took place, in the case of the girl, I found that the thermometer stood at 104.2-5 degrees, but this high temperature may have been caused by inflammation going on in the chest, evidence of which was discovered after death.

In this case, as also in Case 4, changes were found to have taken place in the Peyerian and mesenteric glands, the latter being enlarged, inflamed, and indurated. In only one of the cases was the spleen enlarged, but in both it was dark and pulpy.

Case 5 is a good example of that form of typhoid fever in which hæmorrhage takes place. In this boy there was apparently a hæmorrhagic diathesis for the time being, for the fever was ushered in and ended by bleeding from the mucous membranes, and there was purpura besides.

DISLOCATION OF THE HEAD OF THE HUMERUS ON THE DORSUM OF THE SCAPULA.

By JOHN HAMILTON,

SURGEON TO THE RICHMOND HOSPITAL.

CASES of this dislocation are so rare, Sir A. Cooper having only seen two cases in thirty-eight years in his extensive hospital and private practice, and M. Malgaigne, with all his research, had up to 1855, when his great work on "Fractures and Dislocations" was published, only been able to collect the records of thirty-four cases, that I am induced to relate an instance of it which I met with a few days ago. On Friday, March 23rd, I was asked to visit a gentleman at Garville-avenue, Rathgar, who had put his shoulder out by a fall from his horse. I found a strong muscular man, about 38 years of age, lying on his back in bed, supporting the left forearm with his right hand. A glance at the left shoulder led to the conclusion, that the shoulder was dislocated, but the deformity was not that with which we are so familiar in the dislocation downward into the axilla, or that forward under the clavicle. The acromion, indeed, appeared prominent, with a flatness below it, as in those dislocations, but this was only in front, it was full behind, constituting a prominence. The elbow, too, was close to the side, and the axis of the humerus went upwards and outwards, external to the situation of the glenoid cavity. The anterior wall of the axilla, formed by the great pectoral muscle, looked flaccid, and felt quite soft and relaxed, and the fingers could be readily passed under the acromion into the vacant space left by the departure of the head of the humerus from the glenoid cavity. The most convincing proof, however, of the nature of the dislocation was the head of the humerus forming a round tumour on the back of the scapula below the spine. Its shape could readily be felt, and the motions of circumduction or rotation given to the arm perceived to be communicated to it.

In the two other dislocations power of motion is con-

finued, the head of the humerus feeling as if locked in its unnatural position. Here, on the contrary, extensive motion could be given to the arm; he also suffered much less pain. I could not help being struck by the great difference in this respect, in a woman whose humerus was dislocated forward on the same day by having been blown down by the wind, and falling on the shoulder. In her, motions given to the arm, or the attempt to put the elbow to the side, from which it was at a considerable distance, and the manœuvres of reduction were all loudly complained of; while in this gentleman the pain was evidently little during the examination or putting the bone into its place. The accident happened an hour and a half before I saw him; his horse having got his foot into a rent and fell forward, pitching the rider over his head, who fell heavily on the left shoulder; from his size and weight the violence must have been great.

The reduction was easy. As he lay on his back I seized the wrist, and with my heel in the axilla, drew steadily downwards and outwards and then inwards towards the centre line of the body. The head of the bone slipped into its socket with an audible snap in less than a minute. I put my heel into the axilla in this case, not for the reasons we resort to it in the dislocation downwards—viz., to use the heel as a fulcrum on which the humerus acts as a lever; or secondly, to push the head of the humerus towards the glenoid cavity, but simply as a counter extending force.

Hospital Reports.

ST. VINCENT'S HOSPITAL.

(Cases under the care of Dr. MAPOTHER.)

Reported by Dr. BELCHER.

THE following cases are selected from several to which Dr. Mapother kindly drew my attention during some recent visits to St. Vincent's Hospital.

The first case may be termed one of

HYSTERICAL TETANUS.

It differed from true tetanus in some important particulars, which will appear from the record of the case, but chiefly in these:—

The tonic spasms were local only; and the symptoms supervened *almost immediately* on the occurrence of a slight punctured wound.

With regard to the latter fact, Dr. Mapother reminded me of an analogous, but equally rare case, recorded on the authority of Professor Robison of Edinburgh, by Dr. Watson, in his "Lectures" (vol. i., p. 573, 4th edit.)

"Professor Robison of Edinburgh, was once at table when a negro servant lacerated his thumb by the fracture of a China dish. He was seized with convulsions almost instantly, and died with tetanic symptoms in a quarter of an hour. Such rapid progress as this, however (adds Dr. Watson), is quite out of the usual course of the disease"—probably fright had something to do with it.

The details of Dr. Mapother's case are as follow:—

C. B., ætat. 16, by occupation a milliner, a resident in Dublin, and unmarried, was admitted into hospital on the 22nd of March, 1866, under the care of Dr. Mapother. Previous to admission she had worked for ten hours daily; her menstrual functions were in general regular, though obstructed at the above date; and she was perfectly healthy in other respects.

The immediate cause of her admission was the occurrence of a slight punctured wound, which was to be seen between the thumb and first finger of the right hand, and was occasioned by one point of a small pair of scissors. This happened on the 16th March. Within ten minutes after she

occurrence of the accident, she began to experience a gradually extending sensation of stiffness in the biceps muscle of the right arm. On the night of the 19th March, the rigidity extended to the muscles of the neck.

On admission on the 22nd of March she could scarcely walk up stairs to her bed; her body was bent to the right side, her left leg was also affected, and her hip was sore. Her pulse was 120. She was directed to take one-eighth of a grain of extract of belladonna in a pill every four hours; also to have ice applied to the spine and the back of the neck for six hours, and to have a turpentine enema twice. In the evening her pulse had fallen to 68. The pills were continued up to the night of the 23rd. She was also allowed beef-tea and four ounces of wine. On the 24th I saw her a second time. She was then better; was not taking any medicine, and her diet was mainly composed of tea, eggs, and beef-tea. She now has the globus hystericus in the throat, and feels great difficulty in swallowing, though not by any means so much as she felt at the time of her admission. The local treatment of the wound was simply poulticing.

March 28th: On the 26th and 27th she could scarcely swallow anything. She is now a little improved in this respect; but her throat is still much complained of. Pulse 92; tongue clean. She has pain in the arm, but not in the thumb. She also has pain in the abdomen which had suddenly become tympanitic. The wound is now healed. For this symptom turpentine enemata were ordered.

April 4th: This day I saw the patient sitting up by the fire. She still has the globus hystericus with difficulty of swallowing; but she has not had any medical treatment beyond the local application of a liniment composed of linimentum saponis with opium.

The second case was one of

DROPSY FROM BRIGHT'S DISEASE.

C. D., ætat. 45, married, a bread-cart driver, and a resident in Dublin, was admitted to St. Vincent's Hospital on the 9th of March, 1866, under the care of Dr. Mapother. He states that about twenty years ago he fell on his ribs, one of which was broken by the fall; and that a swelling (emphysematous?) of his body and legs resulted. At that time he was treated in Jervis-street Hospital.

Previous to admission to St. Vincent's Hospital on the 9th of March, as before noted, he was stated to have had œdema in the lumbar region, in the two legs, and in the face, but he was entirely free from ascites.

He was directed to take a vapour bath nightly, and a carbonate of potash mixture (ʒss. ad. ʒviii.). On the night of his admission he also took one-third of a grain of elateium in ʒi. of compound jalap powder. At the date of my first visit, 21st of March, he felt better. Before this date his urine had been examined, and the result showed the sp. gr. to be 1015. It deposited abundant mucous casts, and was, moreover, heavily loaded with albumen. He had passed a large quantity in the twenty-four hours, but previous to his admission to hospital he had micurated frequently, passing very small quantities each time, as he tersely expressed it, "little and often."

At this date, however (21st of March), he was on a liberal diet of meat and eggs, while the urine had diminished in quantity and also in albumen.

March 24th: I saw him a second time. He has passed about five pints of urine during the preceding twenty-four hours; the albumen is about quarter of the volume of the quantity tested. He loses flesh, and has constant perspirations, though he considers himself to have improved very much since his admission to hospital.

At my next visit, on March 28th, I found that he had left the hospital by his own desire on the previous day, and Dr. Mapother was of opinion that while his symptoms were much relieved, yet that a return to his ordinary daily life would certainly bring them back in an aggravated form. The practical point in this case is the mode in which an incurable disease can be quickly and sensibly alleviated by the plan of treatment just described.

The third case is one of

PSORIASIS AGGREGATA, TREATED BY IODIDE OF POTASSIUM, AND THEN BY DONOVAN'S SOLUTION.

Mary K., ætat. 31, unmarried, a native of the county of Meath, was admitted to St. Vincent's Hospital on the 14th of February, 1866, under the care of Dr. Mapother, with a cutaneous affection of ten months' standing.

The eruption was on the skin of the limbs and trunk generally, and was of the kind denominated by Willan, Psoriasis diffusa; by Rayer, Ps. confluens; by many modern dermatologists, Ps. vulgaris; and by Dr. Neligan, Ps. aggregata (2nd edition by Dr. Belcher, page 251).

The treatment adopted in this case was very successful, combined, as it was, with the exhibition of liberal diet. On admission Dr. Mapother directed her to take a vapour bath nightly, and one ounce of a mixture of iodide of potassium (ʒi. ad. ʒviii.) three times daily. On the 20th of March she showed symptoms of iodism. The iodide of potassium was accordingly stopped, and instead of it she commenced to take three times daily an ounce of a mixture containing ʒss. of Donovan's solution to ʒviii. of water.

The case was nearly well when I saw it on the 27th of March.

April 4th: This day Dr. Mapother again showed this case to me. It is as successful as any practitioner could desire such a case to be.

SUMMARY OF SCIENCE.

(Specially Edited and Compiled for the Medical Press and Circular).

By CHARLES R. C. TICHBORNE, F.C.S.L.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of the statements made by any of the papers quoted in the compilation.]

POISONOUS EFFECTS OF MERCURIC METHIDE.—Some excitement has been produced upon the Continent from the publication of an account purporting to be how they poison German assistants in English laboratories. These attacks were the more strange as they were the refrain of a statement made by an English chemist (a Dr. Phipson), who in an uncalled for and unjustifiable paper in *Cosmos*, falls foul of the wrong man, Dr. Frankland. Unfortunately, however, this attack was produced from two lamentable accidents which really took place at St. Bartholomew's Hospital, an account of which is published in their "Reports." The action of mercuric methide possesses some considerable therapeutic interest. The replies of Dr. Frankland and others to Dr. Phipson's attack are published in *Cosmos*. The two cases of poisoning are very curious, and before describing the cases as recorded in the Hospital Reports, we will give a short account of the method by which mercuric methide is prepared. It is from a paper published by Messrs. Frankland and Duppa in the journal of the Chemical Society for December, 1863, also in vol. viii., page 262, of the *Chemical News*.*

A mixture of ten parts by weight of iodide of methyl and one part of acetic ether is treated with sodium amalgam, the flask containing the ingredients being alternately agitated to promote the reaction, and plunged into cold water to moderate the rise in temperature. To the neck of the flask is attached a small upright Liebig's condenser, to arrest the vapour of iodide of methyl. When the reaction has terminated the contents of the flask are distilled, and the ethereal distillate, after separation of the water, first agitated with alcoholic potash to remove the acetic ether (which takes no part in the reaction), and afterwards well washed with water. The product now exhibits the boiling point and other properties of mercuric methide. Mercuric methide is a colourless, strongly refracting liquid, having a faint and somewhat mawkish taste. Specific gravity, 3.069; boiling point, between 93°

* On a new method of producing the mercury-compounds of the alcohol radicals. By E. Frankland and B. F. Duppa.

and 96° C; vapour density obs. = 8.29; calc. = 7.97. It is insoluble in water, very soluble in alcohol and in ether; dissolves phosphorus, caoutchouc, and resins easily, sulphur in small quantity. We may presume that in ignorance of the poisonous qualities of the vapour, all these operations were conducted in the open laboratory, and not under a hood or in a closet. The cases were—C. W., aged 30, admitted into hospital wards 3rd February, 1865. He was a German assistant in the laboratory of St. Bartholomew's Hospital. He died on February 14th. The other case is perhaps of still greater interest. We do not give the particulars, as they will be found in No. — of THE MEDICAL PRESS, page —. Iodide of potassium was largely administered to each of these men, and it seems that after taking the iodide they became rapidly worse. (Can the employing of iodide of potassium in such cases be right? It is certainly not in accordance with a chemical view of the rapid elimination of a mercurial compound.) Melsens, however, makes the following observations upon this subject:—

The first effect of the administration of iodide of potassium in cases of mercurial intoxication, is sometimes to revive and exaggerate the action of the poison. This, however, he adds, is a condition necessary to a perfect cure, and suggests the continuation of the remedy in larger and larger doses.*

Melsens, indeed, administers the iodide in very large doses, and states that it is never followed by any ill effects of its own when perfectly pure.

He states that he has proved the elimination of the mercury in combination with the iodide by the urine, in cases of mercurial palsy, and also the absence of the metal in that excretion after a cure was effected. But Melsens's writings on that subject, are no doubt well known, and we need not refer to the matter further.

The Editor of the *Chemical News* remarks that it is much to be regretted that these interesting cases have been recorded entirely without comment, and it would appear that for aught that has been learned from their sufferings, beyond the symptoms, these unfortunate martyrs to science will have died in vain. There can be no doubt that we have all the symptoms which have occasionally been observed in the case of water-gilders and quicksilver miners, but greatly intensified. It must be remembered that mercuric methide contains 87 per cent. of mercury, and it would seem that the peculiar combination in which it is presented facilitates the absorption of the metal, and enables it, so to speak, to penetrate the system more profoundly. Whether nature makes any spontaneous effort at the elimination of the poison we are not informed.

UPON THE COMPOUNDS OF CHLORIDE OF ZINC WITH THE ALKALOIDS.—M. R. Graefinghoff (*Bulletin de la Société Chimique de Paris*) describes his processes for making these. The salts found are crystallizable. The author gives the following as the composition of them:—Chlorhydrate of chlorozinc toluidine ($C_{14}H_9N + ZnCl_2$) + HCl. chlorozinc toluidine $C_{14}H_9N + ZnCl_2$.

Chlorhydrate of chlorozinc strychnine (obtained on adding a solution of strychnine in alcohol to an alcoholic solution of chloride of zinc, hydrates oxide of zinc precipitates, and the new salt is procured from the liquor by crystallization. The composition is, according to the author, ($C_{42}H_{22}N_2O_4 + ZnCl_2$) + HCl.

A second compound with strychnine, having the composition ($C_{42}H_{22}N_2O_4 + ZnCl_2$) + HCl. + 2 aq., is described.

Combinations of chloride of zinc with morphia.—Two are described—viz., Chlorozinc-morphine, $C_{31}H_{19}NO_6 + 2 ZnCl_2 + 4 aq.$, and a compound $C_{31}H_{19}NO_6 + 2 ZnCl_2 + 14 aq.$

Combinations of chloride of zinc and quinine.—Chlorhydrate of chlorozinc quinine ($C_{40}H_{24}N_2O_4 + ZnCl_2$) + 2 HCl. + 2 aq.; and chlorhydrate ($C_{40}H_{24}N_2O_4 + ZnCl_2$) + 3 HCl. + 3 aq.

Two similar salts of chinconine are described. Chloride of zinc has a great tendency to unite with the organic bases, and corresponds in this respect with the chlorides of platinum, palladium, gold, or mercury. If the organic base is volatile, it forms with chloride of zinc a chlorine product which is volatile, and this, in the opinion of the Editor of the Summary, might be made available in procuring conium, nicotine, &c.

ON THE PRESENCE OF LEAD IN TINNED VESSELS.—By a French ministerial instruction of the 11th of June, 1863, it has become necessary to examine all the tinned vessels that are used in the military hospitals of France. The simple method proposed by M. Jemmel is as follows:—Five decigrammes of the metal are treated with an excess of nitric acid diluted with one-third its weight of water, and the whole made to boil. To the filtered liquor, a crystal of iodide of potassium is added. If the liquor only contains 1-1000th of lead it will produce a yellow precipitate, which is very apparent and does not disappear upon the addition of ammonia.—*Journal de Pharmacie et de Chimie*.

ON MANNITE IN THE OLIVE TREE AND SPECULATIONS UPON THE FORMATION OF THE OIL.—Most of our readers had, no doubt, observed in the late Exhibition, some bottles in the Italian department, sent by S. de Luca, Professor of Chemistry at the University of Naples. They contained specimens of mannite procured from different parts of the olive tree. This sugar, called mannite, from its being found in manna, is contained ready formed in many plants, and seems to bear a somewhat similar rôle in vegetable economy to ordinary saccharine or amylaceous food in animal physiology. The following part or parts of plants contain mannite at certain seasons of their growth in large quantities:—roots of *aconitum napellus*, celery, *triticum repens*, camella alba, coffee-beans. Ergot of one year contains mannite, but not that of another year's growth, as it is connected with mycelo, many fungi. On algae, also, there is often found an efflorescence of mannite. Mannite is usually prepared from manna which is treated with boiling alcohol, and the alcoholic solution allowed to crystallize. On cooling mannite is deposited. It is purified by re-crystallization, and is very easily obtainable in a high state of purity. Mannite differs from sugar in its power of resistance to heat, as it may be distilled without much decomposition. It does not become syrupy on being spontaneously evaporated; in this respect it differs from sugar also. It also does not exert any action upon polarized light. Mannite is a substance that bears a closer analogy to glycerine than even to sugar. Like glycerine, it forms a nitro-compound (nitro-mannite), which explodes very violently when struck. It is prepared by breaking mannite with strong nitric and sulphuric acid. It forms beautiful fine white acicular crystals, insoluble in water, but soluble in alcohol and ether. It has been proposed to use nitro-mannite for charging percussion caps.*

Professor de Luca has shown that mannite exists in different proportions in every part of the olive tree. This saccharine principle is not always found in the same quantity at all stages of vegetation. At the period of blossoming it accumulates in the flowers and diminishes in the leaves. The fallen flowers having once completed the phenomenon of fecundation no longer contain any mannite; it has likewise been found impossible to obtain the slightest traces of it in the yellow fallen leaves.

Mannite exists in the fruit as long as it continues green, diminishing in proportion as it ripens, and disappears entirely when it becomes perfectly ripe and contains the greatest quantity of oil. In a communication to Mr. Tiehborne, Professor de Luca says that these investigations were commenced in the year 1858. Experiments

* Nitro-glycerine is used for blasting rocks, and is at the present time being successfully used in making the heavy cuttings for the new Dublin Water Works. Nitro-mannite, if it could be made available for similar purposes, has the advantage of being a solid, whilst the nitro-glycerine is a fluid.

* See "Memoire sur l'emploi de l'iodure de potassium, pour combattre les affections saturnines et mercurielles." 7 Bruxelles, 1865.

are still going on to determine at what period of vegetation the fatty matter was formed in the olives, and what is, or what are, the materials which have given it birth. The olives at the commencement of their formation contain a green, and traces of a fatty, matter; but, proportionally as the fruit of the olive develops itself and increases, the fatty matter develops itself and increases also.

The chlorophyll, green-colouring matter, which was found in abundance in the leaves and fruits of the olive tree, always accompanies the mannite. The saccharine matter exists in small quantities when the leaves begin to develop themselves; it augments with their progression, diminishes during the flowering of the plant, and when the leaves begin to lose their green tint. It disappears, however, when the leaves are yellow and fall spontaneously from the plant. The leaves of the olive tree are perpetual—that is to say, they do not become detached from the plant until the new green leaves become formed and developed. When the fruits are perfectly ripe, and have lost their green tint, they contain no mannite. When the mannite is exhausted the oil is at its maximum. The decrease of the saccharine and green matter in the olives during the increase of the fatty matter, and the disappearance of these same substances, when the olives contain a maximum of oil, show that there must exist some relation between all these matters, and that if the chlorophyll and mannite are assimilated, it is that they give foundation to some other substances, amongst which must figure the olive oil.

Dr. ALDERSON, F.R.S., President.

NOTES AND OBSERVATIONS ON FEVER DURING SERVICE ON BOARD H.M. SCREW CORVETTE, "PYLADES," ON THE WEST COAST OF MEXICO IN THE YEAR 1860. (WITH MAP.)

By JOHN CADDY, M.D., Surgeon, R.N.

(Communicated by Dr. HODGKIN.)

AFTER referring to the previous services of the *Pylades* at Calcutta at the time of the Indian mutiny, and the subsequent beneficial change produced on the crew by the climate of Vancouver's Island in 1859, the author gave a statistical statement of the fever cases on board when on the west coast of Mexico in 1860, and drew inferences as to the greater liability of attack in the ratio of greater age, and of the excess in length of the sickness when treated on the coast to that treated in the ship.

The climates and geographical position of Mazatlan, Panama, La Paz, Guaymas, San Blas, &c., and the comparative lengths of their dry and rainy seasons, were then described. The *Pylades* arrived at Mazatlan in January, 1860, and details were given of the first cases of remittent fever which occurred on board as they entered the Mexican tropics. Numerous cases of continued fever followed after the 21st of February, which were considerably added to by the occurrence of duties which involved much solar exposure, and the constant alternate landing of officers and men for duty on shore at San Blas, up to the beginning of June. The number of cases increased during the short passages between Mazatlan, La Paz, and Guaymas up to the end of September; but from that time the men's health improved as the cool season advanced.

The author then described the general symptoms seen in patients when first attacked, and the usual course of those developed as the fever increased. Only one case proved fatal. Black vomit was of rare occurrence, it being unknown in the fevers at the commercial towns of San Blas, Mazatlan, and Guaymas

The author, in describing his treatment, which proved most successful, included fresh breathing-air, personal ablution, close cutting of the hair, full supply of cooling drinks (those made with the mineral acids being preferred), pouring of sea-water on the head, mustard sinapisms and chloroform liniments, and the giving of sesquicarbonate of ammonia in conjunction with chlorate of potash early in the fever, the ammonia having been suggested to the author by a previous West Indian experience in 1845-47, and at Calcutta in 1858. With the cessation of active symptoms, quinine and iron usually and speedily concluded the treatment of the cases. The value of the above treatment, the author said, he had been able to confirm by a subsequent ten months' service in the Gulf of Mexico in 1862, and again among the West Indian Islands in 1863 in H.M. screw frigate *Phaeton*.

Details followed of the total number and length of cases of fever in these later expeditions, and a summary of other diseases, which made up the total of 518 cases of sickness on board the *Pylades* in 1860, concluded the paper.

The PRESIDENT said the disease could not have been grave, or the treatment must have been very good, to have resulted in so great success. There had been no autopsy to confirm any opinion as to the type of the fever.

Mr. GASKOIN thought papers on fever sent by surgeons from remote parts of the world were most welcome contributions. He supposed the fever in Dr. Caddy's cases was remittent, as during recovery it assumed an intermittent type, and there were as complications hemierania and paralysis. It was not clear to what this fever could have been due. Attention had recently been directed to the effect of "coaling" under an ardent sun as a possible cause of fever. Mr. Gaskoin concluded by saying that a few months ago he saw in St. George's Hospital cases of spotted fever treated by ammonia, and that—whether the ammonia was theoretically wrong or not—the patients thus treated did well.

Dr. CADDY said his object was to bring forward the treatment by ammonia as treatment against that by calomel every four hours. The calomel treatment produced hypercatharsis and retching, and these were supposed to be symptoms of the disease. His treatment by ammonia had been suggested by the valuable researches of Dr. Richardson. He (Dr. Caddy) had observed that cases of tropical fever—the so-called yellow fever being an exaggerated type of tropical fever—terminated sometimes by serous apoplexy. In ammonia a readily absorbable pabulum was supplied to the blood; it stimulated the heart and arteries without exciting the brain.

Dr. HENRY G. WRIGHT asked if the author had noticed any difference in the fevers in different races of men. He (Dr. Wright) had crossed Panama in 1852, whilst the railway was making. There was an hospital for Chinese coolies, who died at an enormous rate. They, however, would not stay in the hospital, but went out into the woods to die. He had asked the doctor (an American) if he had observed any difference in the symptoms when the fever attacked a Chinaman or a native. The only thing was that the Chinese did not suffer from headache, and this might be explained by the fact that a Chinaman always walks about with his head uncovered, unless he can afford the luxury of an umbrella.

Dr. CADDY said he had had no experience of fevers attacking Asiatics.

Dr. WEBSTER said that cases of fever on board ship were milder than cases on shore. This had been remarked in many parts of Europe. He instanced the yellow fever at Lisbon.

Mr. SPENCER WELLS said most naval surgeons would differ from Dr. Webster, as they frequently observed that men newly arrived in places where any disease was epidemic suffered much more severely than the acclimatised inhabitants. Many instances could be referred to where sailors suffered severely from remittent and intermittent fevers soon after arriving in places where the residents were quite unaffected. Then, with regard to the coolies

in Panama, rather than accept the American doctor's explanation of the difference in the symptoms of fever being due to the covering or non-covering of the head, he should think the question one of race and climate. When any endemic, epidemic, or contagious disease appeared for the first time in any of the chief varieties of the human race, the mortality was much greater than when it attacked a race of men who had been protected by a previous attack, or had inherited some protection from forefathers who had suffered.

Dr. WRIGHT said the inhabitants of Panama were chiefly emigrants from the United States.

Dr. POLLOCK considered that the author's cases illustrated a form of gastric remittent fever with which he had formerly been familiar when practising at Rome, and which appeared to him to be dependent on malarious influences less powerful than those which determined the more perfect forms of tertian or quotidian. The Roman fever was characterized by great prolongation (many cases lasting from forty to sixty days), by daily exacerbations without distinct remissions, and by marked irritation of the gastro-intestinal mucous membrane, and hence by vomiting, diarrhoea, and a morbidly clean and red glazed tongue. Above all, there was much intolerance of drugs. He (Dr. Pollock) had lost many cases by an over-active and so-called heroic treatment in the early days of his practice, and had, in the latter years of his residence in Italy, often declared to the friends of the patient that he felt bound to abstain from prescribing. Quinine was tolerated only when the gastric irritative symptoms had manifestly subsided, and the type of fever was much less under the control of anti-periodic remedies than the more defined intermittents. The treatment described by the author (ammonia in effervescence with citric acid) did not appear to Dr. Pollock to be identical with that by uncombined ammonia, which possessed directly stimulating properties little likely to meet the requirements of the case.

Dr. CADDY said that at first he gave the ammonia with lime-juice, but afterwards unmixed. He had observed that the acetate of ammonia purged; the citrate agreed well.

Foreign Medical Literature.

ABSTRACT OF METEOROLOGICAL AND MEDICAL OBSERVATIONS TAKEN AT THE MILITARY HOSPITAL, NICE,

FROM THE 20TH TO THE 31ST MARCH, 1866.

By Dr. CABROL,

CHIEF PHYSICIAN TO THE HOSPITAL.

Translated by R. CROTHERS, M.D., M.R.C.P.L., Nice.

THE barometer has gradually risen since the 21st, when it was 0.745; it is now 0.765, indicating settled fine weather. This steady rise was not even interrupted by the storm which burst forth on the morning of the 23rd, and also the rain on that and the following day. There was only a momentary fall on the morning of the 25th, which coincided with a sudden gust of wind from the N.W. and with extreme dryness of the air (32°); this day presented the lowest point of relative humidity for the entire month of March. We may remark that the fall of the barometer at Nice indicates more certainly the approach of a sudden gust of wind than rain—a fact already noted on the day of the 14th, as in our last report. In the beginning of this decade the ground was wet, the water of the Paillon was yellowish, the sea rough. For some days past all is changed; the ground is dry, the dust, at times, even annoying, the Paillon has resumed its ordinary volume and colour, the sea (with the exception of slight disturbance

on the 23rd) has remained almost perfectly calm. The mean temperature has risen to 55° Fahrenheit—a height to which it had not attained since the commencement of the month. The minimum to-day is 44°, whilst we remarked that it was only 34° in the middle of the month. We have observed the thermometer above 86° in the open air and sunshine, and above 104° under glass. The winds have been moderate but extremely variable; those from S. and especially S.E. were most frequent. The evenings and nights have been clear, calm, beautiful, and free from damp.

En résumé. This last fortnight may be divided into two periods. In the first period damp and rather cold, the winter indeed, the last days of it being rainy, with winds and a large amount of ozone, but exempt from frost and snow. With the second part came fine weather, of which everything promises a continuance.

For some days past vegetation has made rapid progress; open-air amusements, walking parties and excursions of all kinds are common, every one feeling the benefit of the mild temperature, and absence of disagreeable winds. Above all, invalids experience the benign influence of this favourable change of weather. Whilst very lately we observed affections of an inflammatory kind, "des embarras gastriques fébriles,"* bronchitis, pleurisy, and even slight attacks of pneumonia in those who had formerly suffered from this disease in a more rigorous climate, at present we have almost nothing to notice under the head of diseases. The diseases of the early days of this decade were the result of an atmosphere damp and almost cold, as remarked in our last bulletin, and the evident amelioration which we now observe is owing to the happy change of weather and season, so that it only remains to the physician to notice the absence of all fresh attacks of disease and the favourable progress of those formerly contracted.

THE MUTUALLY ANTIDOTAL PROPERTIES OF OPIUM AND BELLADONNA

ARE made the subject of a paper by Dr. Henry S. Downs of New Ycrk, published in the Transactions of the State Society of last year. Eleven cases are detailed, of which we give a synopsis.

Case 1.—Infant, three and a half months old, had been given about one teaspoonful and a half of a preparation of paregoric nearly one-half stronger than the tinct. opii camph., U.S.P. Narcotism, deglutition difficult, pupils contracted to the size of a small pin's head. Child was only kept aroused from stupor by severe and continued agitation. About six hours after the administration of the dose, ten drops of tinct. belladonna were given, and repeated at intervals of fifteen minutes until forty drops were given, when the pupils were dilated to double, and in one hour to treble the former size. Improvement rapidly followed. (Dr. Downs.)

Case 2.—Woman, æt. 35, had taken one-half ounce of laudanum suicidally. Seen an hour later, partially sensible. No emesis could be induced by ipecacuanha, sulphate of zinc, tartar emetic, or mustard. She became insensible, pupils contracted to the size of a pin's point; profound stupor, from which she could not be roused. One drachm of tinct. of belladonna was then given, followed by two grains of the best English extract of belladonna every twenty minutes, until six grains were taken. Soon after the third dose the patient vomited, the ejecta smelling strongly of opium. Sensibility gradually returned, and at the end of eight hours pupils were natural, sight

* Embarras gastrique. This term signifies disorder of digestion, with nausea, vomiting, and often colic and diarrhoea. It is divided into two forms—namely, "Embarras Stomacal" and "Embarras Intestinal." The first characterised by headache, loss of appetite, bitterness of the mouth, white or yellowish coating on the tongue, nausea and tenderness of epigastrium. The second form by lassitude, eructations, barborygni, tension of abdomen, wandering pains in thighs and legs, more particularly in the knees.

restored, and consciousness complete. (Mr. Loines and Dr. Jones.)

Case 3.—Woman, had taken one and a half ounces of laudanum. All the symptoms of opium poisoning present. Emetic first, then a reliable tincture of belladonna, thirty drops every half hour, until ninety drops were taken. Rapid recovery and no indications of her having taken belladonna. (Dr. Wm. H. Thompson.)

Case 4.—Soldier, took two ounces of laudanum and smoked one grain of opium. Three hours afterwards was found comatose, pupils contracted, and slightly spasmodic. Forty drops of tinct. belladonna were given at half-hour intervals, until he had taken 120 drops, and then in half an hour twenty drops more, when he began to improve, and entirely recovered in a few hours, with no signs of having taken belladonna remaining. (Same authority.)

Case 5.—Soldier, took over an ounce of laudanum. About an hour afterwards drowsy, face flushed, pulse low, pupils much contracted, hands twitching, tendency to convulsions. One grain of extract of belladonna every half hour until three grains had been given. Two hours after first dose of belladonna, the pupils had dilated, pulse and skin natural, and able shortly after to go on duty. (Dr. Charles D. Hackley.)

Case 6.—Infant, eight weeks old, had been fed on Mrs. Winslow's soothing syrup until complete recovery was impossible, even by the aid of belladonna. (Dr. C. C. Terry.)

Case 7.—Belladonna poisoning occurred in a young woman who used belladonna pessaries for the purpose of allaying the excruciating pains of ovarian dysmenorrhœa. The toxic effects were suddenly developed to delirium. One and a half grains of Magendie's sol. sulph. morphia entirely removed the symptoms of poisoning an hour after delirium appeared. (Same authority.)

Case 8.—Belladonna poisoning from use of belladonna pessaries. Opium used with same good result. (Same authority.)

Case 9.—Child, through mistake, took one teaspoonful of laudanum. An hour later comatose and incapable of being roused. Ten drops of tinct. belladonna every hour until sixty drops were taken, when narcotism subsided and the patient slowly but gradually recovered. (Dr. J. P. Garrish.)

Case 10.—Man, took one ounce of laudanum. When seen, two hours later, feeble pulse, contracted pupils, stertorous breathing, and could not be aroused. Emetic first, and twenty drops tinct. belladonna every hour until about ninety drops were taken, when he began to show signs of consciousness, and by the aid of coffee, stimulants, and the cold douche, was gradually restored. (Dr. Garrish.)

Case 11.—Woman, took ten grains of opium. In one hour was found in semi-comatose state, pupils contracted. Emetic, then twenty drops of tinct. belladonna every hour until sixty drops were taken, when consciousness began to return, and she recovered.—*Philadelphia Med. Reporter.*

TUBERCLE IN THE BRAIN.

PROFESSOR DUCHEK has published, as the first of a series of "Studies of Diseases of the Brain," three cases of tubercle in that organ.

1. *Tubercle in the Pons.*—Besides tuberculosis of various other organs, there was found in a young man a tubercle an inch in diameter in the left half of the pons. The surrounding brain was softened, and there was exudation on the membranes. The symptoms corresponded to the well-known type of the disease. At first, gradually increasing paralysis of the right leg, later of the right arm and left facial nerve, and perhaps of the palpebral branches of the oculo-motor nerve. Sensibility was diminished in the left half of the face, and mastication interfered with thorough paresis of the masseter muscle. Electrical contractility was weaker in the affected muscles than in the corresponding ones of the opposite side. Pains, spasms, and stiffness, preceded the paralysis in the extremities,

paresthesia accompanied it. Consciousness remained untroubled throughout the course of the illness; death followed in a year from its probable commencement.

2. *Tubercle in the Corpus Striatum.*—A child, six years of age, was affected with chorea-like movements, at first in the right half of the face, and these soon spread to the neck, shoulder, arm, and leg of the same side. By degrees the affected parts became weaker, and at length wholly paralyzed. Contraction occurred only in the muscles of the nape; sensibility of the skin, and reflex-sensibility, were increased. The perceptive faculties were normal. Micturition very difficult in the daytime, involuntary at night. The intellect was latterly disturbed and clouded. The illness lasted six months. A tubercle, the size of a hazel-nut, was found in the left corpus striatum; and one, the size of a bean, in the upper wall in the fourth ventricle, and many smaller ones in the cortical part of the brain.

Duchek attributes the contraction of the muscles of the nape to the tubercle of the fourth ventricle.

3. *Tubercle in the Cerebral Hemisphere.*—A man, eighteen years of age, who worked very laboriously with the right arm, was suddenly seized with clonic convulsions of it, shortly followed by a like affection of the face and loss of consciousness. At first the convulsions recurred in the same way every fourteen days, later irregularly, even many times a day, but without loss of consciousness. Soon tonic spasms alternated with them. For some months all symptoms of illness disappeared; but then they broke out anew, and seized also on the right foot, appearing for the most part only in one extremity; they also once transiently affected the left foot. Burning pain in the forehead preceded the attacks. Coming on again after a second pause of some months, marked paresis of the right half of the face and of the right extremities was noted. The paroxysms lasted till a short time before death, about two years after the first attack, the patient dying, tuberculous, of marasmus. On post-mortem examination there was found in the left cerebral hemisphere a wedge-shaped tubercle, which, from its broad base at the cortex and attached membranes, extended an inch and a half downwards in the substance of the brain towards the optic thalamus; it was enclosed by a richly vascular membrane; the cerebral substance round it was of a pulpy softness. Elsewhere the brain was healthy.—*Wien. Zisch. (Med. Jahrb.), and Brit. and For. Med.-Chir. Rev.*

OINTMENT OF RED OXIDE OF MERCURY.

In the ointment of red oxide of mercury B. P., nitric oxide of mercury is directed to be used. Mr. Squire advocates the use of the precipitated oxide in preference; he assigns, as advantages, that supposing ointments of equal therapeutical value to be used, greater economy is gained by the use of the precipitated oxide, since a less proportion of it will suffice in the same quantity of ointment; that, when nitric oxide is used, the application of the ointment to the skin leaves a quantity of the scales of the salt upon the skin, while, at the same time, a different action is produced to what is sought for when an ointment of red oxide of mercury is employed. Ointment made from precipitated oxide possesses the advantage of a perfectly smooth appearance; and its application is free from the inconvenience of gritty particles and red scales left upon the skin of the patient, as well as possessing superior efficacy.—*Pharm. Jour.*

ON THE SOLUBILITY OF SALTS IN MIXTURES OF ALCOHOL AND WATER. (GERARDIN.)—The results obtained by the author are—1. All salts insoluble in alcohol and soluble in water have, in mixtures of alcohol and water at a constant temperature, a solubility decreasing as the proportion of the water in the mixture is diminished. 2. The solubility of these salts is not proportional to the amount of water contained in the mixture, The quantity dissolved is always less than would dissolve in the same amount of water by itself.—*Ann. de Chimie et de Physique.*

MEDICAL GLEANINGS.

(From the British and Foreign Medico-Chirurgical Review.)

A Case of Double Uterus and Vagina. By Dr. Rabe.—A healthy woman, aged 20, was admitted in May, 1865, into the Town Hospital of Dresden, for blennorrhœa and excoriations of the vulva. She had menstruated since sixteen. The external genitals were normal, but the hymen was wanting. The vagina was double, the lower end of each half being provided with a hymen-like fold of mucous membrane. In the summit of each vagina was a small firm vaginal portion of uterus, each possessing a small transverse os. The uterine sound passed freely into the left os uteri, but only slightly into the right, so that it remained doubtful whether the body of the uterus had two distinct cavities.—*Monatsschrift für Geburtskunde.*

A Case in which the Meneses were apparently substituted by Hæmorrhage from the Skin.—The subject of Mr. d'Andrade's case was a stout healthy Parsee lady, aged 18. She had menstruated regularly from thirteen to fifteen and a half, when catamenia became first irregular, then ceased, being replaced by bleeding at the gums and nose, and vomiting of blood. Menstruation returned; no pregnancy. Mr. d'Andrade observed blood to ooze from the healthy skin of the left breast and of the right forearm. The blood exuded showed red and white globules under the microscope. The skin-hæmorrhage recurred every month or two. Subsequently blood oozed from the forehead.—*Trans. of Med. and Phys. Soc., Bombay, 1862.*

Extra-uterine Gravidity. By Dr. Kammerer.—Dr. Kammerer related a case and presented the specimen to the New York Obstetrical Society, of extra-uterine gestation. A woman, aged 30, had been under treatment for chronic metritis. Seven or eight years previously she had a child. She became again pregnant, and a little time subsequently was taken suddenly ill, with symptoms of internal hæmorrhage and peritonitis, and in the course of a few hours died. Several quarts of blood were found in the peritoneal cavity, and on the left ovary a rent revealing the source of the hæmorrhage. On opening the ovary an embryo was discovered about four weeks old.—*New York Medical Journal.*

The above history is very brief, but appears to be precise. If the facts are correct, there can remain no doubt of the possibility of ovarian gestation, which has been strenuously denied.

Forty Cases of Artificial Premature Labour.—Dr. Simon Thomas of Leyden, relates forty cases in which labour was artificially induced. The indications were chiefly contractions of the pelvis; and these were determined less by the histories of previous labours than by accurate measurements expressly made. Thus, in five cases, the patients were primiparæ. The first method employed was to place a bougie for a short time a few inches between the uterus and membranes, changing it every day for a larger one. Labour only came on in ten days, and the forceps was used. In another case Kiwisch's douche was used. Labour followed in five days. The mother died of pyæmia. In other cases the bougie was used, or the douche; generally days elapsed before labour. Afterwards Krause's method, the leaving an elastic catheter in the uterus, was used. The time expended was from six to ninety-two hours, the majority taking from twenty-four to forty-eight hours. Of the thirty-two children born after Krause's method twenty-five lived; of the thirty-two mothers twenty-five had a quite natural puerperal history; four died of pyæmia or endometritis.

On Eclampsia Puerperalis.—Dr. Seydel relates five cases of eclampsia. In all albumen was found in the urine before, during, or shortly after labour, and disappeared wholly or in part during childbed. A commentary is appended, in which he discusses the various theories of the etiology of the disease. Traube's view, that eclampsia puerperalis is produced by increased pressure upon the aorta, inducing

œdema of the brain, with secondary anæmia, will, he thinks, account for many, but not for all cases. The theory which (forgetful of British predecessors) he attributes to Hecker, that the cause is the transport of excrementitious matters into the blood in consequence of acute nephritis, he opposes, saying its supports vanish more and more with the advance of clinical observation; for, he observes, the albumen in the urine does not appear by itself without labour, but increases during the act of labour, there having been no albumen during pregnancy; and dissection of persons dead of eclampsia always proves the inadequateness of the kidney affection to account for the acute uræmia. He recalls attention to the view followed by the older obstetricians, and recently favoured again, that the most powerful, perhaps the primary, affection is that of the nervous system. In support of this, Seydel adduces, after Spiegelberg, a group of symptoms manifesting excitation of the sympathetic nervous system; for instance, the dilated sluggish pupils, the spasm of the vessels of the skin which—not indeed without the help of the spasm of the respiratory muscles—causes lividity of the skin; the contraction of the muscular coat of the vessels seen in the paleness of the face, and, after the attacks, the compensating turgor; and, lastly, the remarkable atony of the uterus revealed by hæmorrhages. He thinks the alteration of the nervous system starts from the uterus, and especially its contractile function.—*Monatsschrift für Geburtskunde, Oct., 1865.*

Cæsarian Section on account of a large Fibroid Tumour of the Uterus.—Professor Breslau's case is of peculiar interest. A woman suffered retention of urine and constipation. A large tumour filled the pelvis, pushing the cervix uteri near to the outlet and forwards. The tumour was uniformly smooth, very hard, and immovable. It appeared impracticable to extirpate it; it rose above the symphysis. Prof. Breslau endeavoured to bring about degeneration by transfixing it with needles. This did no harm and no good. She became pregnant. It was resolved, on consultation, that Cæsarian section offered the only means of safety to mother or child. The cord came down and could not be replaced; the left foot could be reached with great difficulty high up. For a moment the bleeding from the incision through the uterus was profuse. Two sub-peritoneal tumours presented themselves on the uterine surface; another, sub-mucous, showed itself in the wound. The child extracted alive. The uterus being emptied, did not contract regularly; it did not sink towards the pelvis, nor did the sides of the wound close. It remained large, and showed a disposition to invert itself. It was necessary to unite the uterine wound. Death followed twenty-two hours after the operation. *Autopsy.*—Only two fingers could be squeezed in the conjugate diameter. The entire uterus and tumour was removed; it weighed five pounds and three-quarters.—*Mon. f. Geburts.*

A Case of Lithopædion, by Dr. Conant.—This gentleman exhibited to the New York Obstetrical Society an interesting specimen of lithopædion. The specimen was the result of the woman's first pregnancy. So far as was known, gestation was normal, and when labour came on Dr. Prescott of Maine was called. Labour pains subsided. Subsequently she had a very offensive perspiration. She recovered, and a hard tumour could be felt in her side. She subsequently gave birth to three children in successive pregnancies. In June, 1863, thirty-five years after the first pregnancy, she died. A calcified extra-uterine fœtus was found, and connected with it another hard mass, which was considered by those who examined it to be the placenta. The whole fœtus was covered by a calcified membrane.—*New York Medical Journal.*

On the Diagnosis of Twisting of the Cord round the Child's Neck.—Dr. Haake, referring to the frequency with which the child's life is threatened from the coiling of the cord around its neck, thinks it desirable that the existence of this complication should be verified before the head is born.

This may be done, he says, by examining with the finger in the rectum. The finger can be easily carried above the head, so as to feel the umbilical cord and its pulsation. This gives a valuable guide to the life-condition of the child, and tells when to accelerate the birth of the head is necessary.—*Zeitschr. f. Med. Chir. u. Geburtsk.*

Rupture of a Varix in the Vagina after Labour, causing Death.—The case of Dr. Helfer is a remarkable example of a rare form of post-partum hæmorrhage. A woman who had borne two children was pregnant for the third time; in the early months varicosities, especially along the vena saphena, crural vein, and pudendal veins of the left side appeared; these increased so that in the seventh month the pudendal varices were as large as grapes and goose-eggs, and walking was difficult and painful. Labour occurred at term, easily. The puerperal state was normally passed. On the fourteenth day she went to household work. She exerted herself in drawing water from a running stream; this brought on pain, and flooding followed. It was arrested by plugging. She recovered for a time. Three days later a second very profuse flooding occurred, in consequence of which she sank. Autopsy showed no mark of peritonitis, no extravasation in the peritoneum. Varicosities on both ovaries, the size of crow and goose-quills; the tubes also varicose; the whole cellular tissue of the pelvis filled with blood-clots running along the posterior wall of the vagina, and proceeding from a burst varix.—*Mon. f. Geb.*, 1865.

CÆSAREAN SECTION: LOCAL ANÆSTHESIA BY ETHER.

ON Thursday, the 29th ult., the first application of the ether spray to produce local anæsthesia during the Cæsarean section was made in a case under the care of Dr. Greenhalgh.

The patient was a woman about 30 years of age, the mother of two children. She was between seven and eight months advanced in pregnancy; but, in consequence of the presence of a large (probably malignant) tumour, at the neck of the uterus, it was believed by Dr. Greenhalgh, Dr. McClintock, and other obstetricians who saw the patient, that delivery in the ordinary way would be absolutely impossible, and that the uterus would possibly be ruptured during labour-pains. It was therefore determined to perform the Cæsarean section without delay. Both Dr. Greenhalgh and the patient objected to the use of chloroform; the objection on Dr. Greenhalgh's part being the liability of this agent to produce vomiting. On the day before the operation, Dr. Greenhalgh consulted Dr. Richardson as to the possibility of producing local anæsthesia. Having no instrument which seemed sufficiently large, Dr. Richardson hesitated to promise complete success, but engaged to make the attempt.

The patient was placed in a semi-recumbent position on a table with her legs hanging over the edge. She was supported by an assistant on each side; and her eyes were bandaged at her own request. Dr. Wilson, of Glasgow, watched the pulse, which was 74, and never varied in power, frequency, or time during the whole operation. To produce anæsthesia, Dr. Richardson used a large instrument with double jet, which he had roughly constructed for the purpose. It acted well; and complete insensibility was produced in forty-five seconds over a space 2½ inches broad from the umbilicus to the pubes. The incision was made direct on the uterus—the patient exhibiting no consciousness of the operation. The uterus being exposed, the ether spray was directed on it for a moment, with the effect of inducing contraction.—An opening was then made in the organ; and, with some difficulty on account of the contraction, Dr. Greenhalgh introduced his hand and removed by the feet a fœtus which was alive, and lived an hour. The membranes burst with the delivery; the placenta was removed separately. The uterus immediately contracted as in natural labour, and required no sutures. The wound in the abdominal

walls was kept open during twenty minutes, a large sponge being held in it so as to guard against bleeding when reaction took place. It was then closed with sutures of Chinese silk, the skin being perfectly narcotised with ether spray at each point where the needle was introduced.

In the morning, before the operation, the patient had felt a tendency to vomit, which passed off, but recurred slightly when the hand was introduced into the uterus. She felt this part of the operation, and asked what was being done. When the membranes were ruptured and delivery was being rapidly effected, she started, and said (as women in labour often say), "I am sure I shall die;" and made a similar complaint when the placenta was being removed. She was slightly conscious of uterine contraction. While the wound was being kept open after the operation she talked on various subjects, but seemed anxious about the delay; she was, however, easily reassured.

The total quantity of ether used in the operation was about six drachms. It was obtained from Robbins of Oxford-street, and boiled at 90°; and, in Dr. Richardson's opinion, the success was in great measure due to its purity.

The operation was witnessed by a large number of obstetricians, among whom were Professors Hugenberger and Lazerawitch (of Russia), Professor Marten and Dr. Marten (of Berlin), Dr. Skaldberg (of Stockholm), Drs. McClintock and Beatty (of Dublin), Dr. Wilson (of Glasgow), Dr. Hall Davis, Dr. Graily Hewitt, Dr. Eastlake, Mr. Spencer Wells, Dr. Protheroe Smith, and many others. Dr. L. W. Sedgwick was also present, and rendered very efficient assistance to Dr. Richardson in the arrangements connected with the production of anæsthesia.

On Tuesday last, five days after the operation, the patient had not had a single bad symptom. The lochial discharge was free; the appetite good; sleep excellent; the mind tranquil and hopeful; pulse 80. The wound had healed throughout by the first intention, and four of the sutures had been removed.

On Wednesday evening, the patient ate and slept well; her pulse was 88; and she was in every respect going on most satisfactorily. During the day she had been temporarily alarmed by the sudden introduction of a new nurse, and the pulse had risen to 120; but, before the evening, her condition, as above described, had resumed its favourable character.

So far as this one case can show anything, the following facts are to be noticed.

1. There was no pain produced by the operation; and what was felt was only such as would occur in a very easy labour.

2. No vomiting occurred, although before the operation the patient had complained of great tendency to vomit.

3. There was no hæmorrhage; so that the operation was not interfered with.

4. There was no shock.

5. The circulation remained steady throughout the whole time of the operation.

6. There was no restlessness. The patient moved once only during the operation—shuddering slightly when the child was born.

7. Consciousness was retained, so that the patient was able to do what she was desired. When asked not to strain, she relaxed the muscles immediately.

8. The case shows that local anæsthesia can be produced in a wound six inches long, extending to the depth of the abdominal walls, without being followed by slough or by peritoneal mischief; the wound healing by the first intention.—*Brit. Med. Jour.*

TRICHINIASIS.—In consequence of the announcement of several deaths from trichiniasis, the municipal councils of Lille, Marseilles, and other towns in France have resolved that the Veterinary Surgeons appointed to inspect the butchers' meat offered for sale shall be supplied with microscopes for a more minute examination

Reviews.

ON SOME OF THE CAUSES AND EFFECTS OF VALVULAR DISEASE OF THE HEART: being the Croonian Lectures of the Royal College of Physicians for 1865. By THOS. B. PEACOCK, M.D., F.R.C.P., &c. &c. London: John Churchill and Sons. 1865.

DESIROUS of drawing attention to causes, other than inflammatory, which tend to the production of cardiac disease, Dr. Peacock exhibits in a tabular form the causes of valvular disease or defect as follows:—

1. Malformation of valves: arterial and auriculo-ventricular, giving rise to regurgitation, obstruction, or obstruction and regurgitation.

2. Injuries of valves: arterial and auriculo-ventricular, immediate and gradual, giving rise to regurgitation, with or without obstruction.

3. Alterations in capacity of orifices and cavities, giving rise to regurgitation from erosion or maladjustment.

4. Inflammatory affections, chiefly rheumatic, acute, and chronic, giving rise to obstruction, regurgitation, or obstruction and regurgitation.

It is to the three first causes of disease that the author purposes to draw attention, as the fourth has been already so fully illustrated by other authors. Dr. Peacock considers the semilunar valves as originally, most probably, consisting of segments which in normal growth become united to form the divisions found in the healthy and fully developed state. In this way he argues, "the excess in the number of the valves is not the result of redundant development, but of an arrest of the proper process of growth. We thus frequently meet with four semilunar valves, sometimes with five, and on the view suggested there is no reason why there should not be six, though I have never in any instance seen that number," &c.

"These changes are found both at the aortic and pulmonic orifices; but the protrusion of the valves is generally most marked at the latter, probably from the right ventricle being the most powerful during fetal life, when the membrane is the most extensible. The condition described I believe to be the result of intra-uterine disease, though other explanations have been given of them. It has been supposed that when there are only two valves, one with a certain much larger than the other, that the angles of attachment of one of the valves may have been torn down from accident. A very cursory consideration will, however, show that this supposition cannot explain the occurrence of the condition in most of the cases in which it is found. Injuries of the kind referred to do occur, but they are certainly very rare, and when they are sustained, they give rise to symptoms of a most serious character, and which cannot be overlooked; whereas the condition described is often found in persons who have never presented any signs of cardiac disease or sustained any serious injury. Blending of the valves, precisely similar in every respect to that described, is also met with in the bodies of young children and infants, and in connexion with other deviations from the natural process of development, which conclusively prove their intra-uterine origin. Thus the pulmonic valves are often found united together in cases in which the septum of the ventricles is imperfect, or where the foramen ovale is unclosed and the ductus arteriosus still pervious—conditions which clearly point to the existence of obstruction at the pulmonic orifice during fetal life."

Cases are quoted in the text and foot-notes corroborative of the position taken by the author.

Instances are given from the practice of Dr. Peacock, as well as from that of Drs. Hope, Thurnam, Bristowe, Stokes, Graves, Corvisart, &c., showing how an extraordinary amount of thickening and obstruction may exist for years in the aortic and mitral valves without giving rise to symptoms of cardiac disease, and where the patient may die from causes unconnected with the cardiac disease, which latter may be first learned only at the autopsy.

The gradual progress of the valvular lesion advancing,

pari passu, with a compensatingly increasing power of the ventricle, may explain the absence of symptomatic evidence during life. "It may, however, be doubted whether the condition is always of congenital origin; but when two or more of the valves are found completely united, I think the probability is that the union took place during fetal life." The author adds, "that auriculo-ventricular malformations in fetal life may lay the foundations of disease in after life" in his opinion.

Of twenty-six cases of aortic valvular disease, nine probably originated in malformation of the valves, and of seventeen cases of combined aortic and mitral valvular disease, two probably so originated; or, in other words, of forty-three cases in which the aortic valves were diseased, either alone or in conjunction with the mitral valves, in eleven, or 25.5 per cent., there was malformation of the valves, which probably laid the foundation of the subsequent disease—a proportion which is much larger than would *a priori* have been expected. Space does not permit us to enter at any length on many other points of interest in Dr. Peacock's valuable work. We would, however, commend his directions as to treatment, diet, &c., in cases of aortic and mitral valvular disease. Speaking of digitalis in cases of aortic disease, he observes on its too frequent and too indiscriminate use; he combats the opinion that it exerts a tonic action on the heart; he regards it as adding to the obstruction to the heart's action already existing from the valvular disease. He gives notices of cases bearing out his opinion on this very important subject. In cases of mitral valvular disease he regards digitalis as eminently useful, more from its diuretic properties, thus lessening the amount of blood, relieving congestion, and promoting the absorption of effused fluid. The remedy, however, requires in all cases to be watched, so as to guard against its influence causing too great depression of the heart.

Dr. Peacock concludes by adverting to Dr. Stokes, who, in his admirable work on "Diseases of the Heart and Aorta," remarks, "that the practitioner should never forget that local diseases, themselves incurable, may co-exist with an excellent state of the general health for a period indefinitely long; and the conclusion is but too obvious, that as the disease cannot be cured, the system at large should not be tampered with."

TRANSACTIONS OF THE OBSTETRICAL SOCIETY OF LONDON FOR THE YEAR 1864. London: Longman and Co.

The volume before us contains many papers of great interest by men of acknowledged reputation in their peculiar departments. We will mention a few, "On Fibrous Tumours of the Uterus," treated by surgical means, by J. Baker Brown, F.R.C.S., &c. The conclusions to be drawn from this paper are briefly these:—1st. That the fact of the curability of these tumours is materially confirmed by these new cases. 2nd. That it is not necessary in many cases to do more than incise the os and cervix, thereby much lessening the danger of the operation. 3rdly. That hæmorrhage is almost invariably arrested by incision of the os and cervix. 4thly. That the cure of these fibrous and fibroid tumours is now fairly established, as proved by the experience of Dr. McClintock, Dr. Routh, Dr. Dawson of Newcastle-on-Tyne, &c., as well as by Dr. Brown himself, by surgical means, without the danger of enucleation.

Another paper containing "Ten Cases of Ovariectomy, with remarks on Hospital Management," by Thomas Bryant F.R.C.S., &c., adds further to our stock of experience on this subject, and Dr. Tyler Smith gives eight additional cases of "Ovariectomy" beside the twelve he has already published in these "Transactions." Dr. Eastlake has a contribution "On the third Stage of

Labour"—viz., the management of the placenta, which, taken with that of Dr. Greenhalgh, "On the Treatment of Placenta Previa, with illustrative Cases," deserve careful perusal. Want of space compels us to give only the following brief abstract of this paper and the twenty-seven cases and aables by which it is illustrated. The practical points to be deduced are the following:—That Nature, unaided every now and then, overcomes this accident with safety both to mother and child; that complete and partial placenta prævia may happen at any age, or in a first or any subsequent pregnancy and at any period of utero-gestation; that spontaneous premature labour is the rule and not the exception in these cases; that a patient may suffer from a few minutes to many hours or days in labour, and in proportion as pregnancy is advanced so is usually the severity of the hæmorrhage, constant or periodic, extending over minutes, hours, days, weeks, or even months; that the change is either in proportion to the amount of blood lost, the suddenness of its flow, or the lengthened period over which it extends; that, notwithstanding the alarming loss of blood, the os uteri and external parts may continue rigid and preclude delivery; that the danger both to mother and child is dependent upon the amount of exhaustion from loss; that in some cases neither the rupture of membranes, the natural or artificial separation of a part or whole of the placenta, nor ergot can be relied upon to arrest hæmorrhage; and that occasionally so alarming is the prostration that no attempt could be safely made to effect delivery; that although turning *per se* cannot be regarded as a dangerous operation, yet when undertaken in cases where the patient has been much reduced, it proved fatal in 131 out of 512 (1 in less than 4), not to mention the amount of foetal mortality. The concluding points of Dr. Greenhalgh's conclusions are, that the effect of plugging, according to his directions, was to arrest hæmorrhage, to excite labour pains, and to promote the dilatation of the os uteri and external parts, and that with repeated doses of ergot, uterine contraction and the descent of the presenting parts were favoured and prevented post-partum hæmorrhage.

ESSAY ON THE NATURE AND TREATMENT OF CHOLERA AND FEVER; with Medical Remarks on the Treatment of the Cattle Plague; also an Appendix on Public Health. By JAMES TUCKER, M.D., &c. Dublin: Falconer. Pp. 40. 1865.

NOTES ON CHOLERA; ITS NATURE AND ITS TREATMENT. By GEORGE JOHNSON, M.D., &c. London: Longman and Co. Pp. 112. 1866.

THE prevalence of cholera in the East and on the Continent with the dread of its approach to our shores, together with the unusual prevalence of typhus fever, and the "plague" now raging among cattle in England, has caused quite an inundation of books, pamphlets, and papers upon these and similar subjects, two of which we have before us.

Dr. Tucker commences with a dedication to Dr. Stevens, couched in terms which, although meant to be highly laudatory of Dr. Stevens' ability, and highly complimentary to him personally, is of a nature which we trust few sensible men would receive willingly with pleasure. As might be expected from the amount of "soft sawder" expended on Dr. Stevens in the dedication, the first portion of Dr. Tucker's pamphlet—occupied for the most part by the consideration of cholera—is chiefly spent in a repetition of Dr. Stevens' views as to pathology and treatment (by salines) without any original matter worthy the name. The portion of Dr. Tucker's essay which relates to the cattle plague starts with a preconceived idea that that disease is identical with typhoid fever in man, which is now known to be very doubtful if not untrue. Dr. Tucker in this chapter quotes the *Times* as "the public press;" we are happy to say there are other journals deserving the name of the "public press" besides

the *Times*, which journal has not of late been in a position to lecture the medical profession, as Dr. Tucker appears to think, and from which he seems to have imbibed some of his rather hazy ideas of medicine. Dr. Tucker concludes with an Appendix on Public Health, which (although the only part of his pamphlet containing valuable information) occupies but one page with what every one knows, winding up with a last quotation from his favorite author, Dr. Stevens.

Dr. Johnson's little volume (a reprint from the *British Medical Journal*) contrasts as favourably with Dr. Tucker's pamphlet, as its dedication to Dr. Watson does with Dr. Tucker's to Dr. Stevens. Dr. Johnson's chief object is to disprove the theory that the collapse in cholera is caused by the loss of fluids and consequent thickening of the blood, and to point out the faults in practice resulting from a belief in this (as he conceives) erroneous opinion. We think, however, Dr. Johnson considers the views which he combats and the lines of treatment he opposes are much more generally received than they really are at the present day. Dr. Johnson deduces very fair and convincing arguments from facts noted by various writers on cholera in support of his views. The author then goes on to state, in a very clear and concise manner, his opinion as to the real cause of the thickened state of the blood; stating his belief that this condition has its origin in an obstruction to the passage of the blood from the right to the left side of the heart, caused by spasmodic contractions of the muscular fibres of the minute pulmonary arteries, and consequent want of proper aëration of the blood. To use the author's own words:—"The blood contains a poison whose irritant action upon the muscular tissue is shown by the painful cramps which it occasions; the blood thus poisoned excites contraction of the muscular walls of the minute pulmonary arteries, the effect of which is to diminish, and in fatal cases entirely to arrest, the flow of blood through the lungs." As to treatment, Dr. Johnson prefers purgatives, condemning the saline treatment of Stevens as merely palliative, the opium and astringent treatment as injurious, and Dr. Chapman's treatment by ice to the spine as a practice the result of a theory which the author looks upon as "a speculative web spun from the projector's brain." In conclusion, we have to recommend Dr. Johnson's carefully written and neatly got up little volume as full of interesting and useful information to all members of our profession.

PHOTOGRAPHS (COLOURED FROM LIFE) OF DISEASES OF THE SKIN. Second Series. By ALEX. BALMANSO SQUIRE, M.B. Lond. No. I. RUPIAL AND LUPOID SYPHILIDES. London: Churchill and Sons.

THE present Photograph represents a case of Rupial Syphilitic Disease affecting the Face. The affection is a tertiary one, the primary disease having been contracted about two years ago, and the secondary having appeared about a month after the commencement of the primary. Nothing is said about the treatment, although it would have been interesting to know whether any or what remedies had been employed. It is incidentally mentioned that some of the sores were treated with "ointment," but the nature of its composition is not described. The representation of the disease is a very faithful one, the original having been introduced to the notice of the Pathological Society of London.

PROGRESSIVE LOCOMOTOR ATAXY: its Symptoms, Diagnosis, and Treatment. By JULIUS ALTHAUS, M.D., Physician to the London Infirmary for Epilepsy and Paralysis. Pp. 39. London: Churchill and Sons. 1866.

THIS paper was read at one of the meetings of the Medical Society of London, and it contains a very good practical account of a disease, which for a long time was but imperfectly understood, but since the researches of Duchenne of Boulogne has obtained a definite place in our nosology. To

the last-named author, however, Dr. Althaus does not admit that the first description of the disease is fairly attributable, and he thinks that the late Dr. Todd described it eleven years before Duchenne. Dr. Althaus's description of progressive locomotor ataxy is very clear, and the indications of treatment, although unsatisfactory, are set forth with great candour and judgment.

THE CAUSES AND TREATMENT OF IMPERFECT DIGESTION. By A. LEARED, M.D. Dub. and Oxon., M.R.I.A., Physician to the Great Northern Hospital, London. London: J. Churchill. Pp. 244.

FEW books have gained a greater or more deserved popularity than the treatise before us, three editions having been disposed of within the six years which have elapsed from its first appearance. This we think is owing in part to the frequency and importance of the maladies of which it treats, but mainly to the lucid style in which the author details his experience and displays his erudition on the subject. Diseases of the stomach especially require a knowledge of the physiological actions of the organ, and for this reason a very able chapter on "The Physiology of Digestion" concludes the work. It would seem to us better placed if it were introductory.

As the former editions are so extensively known, it seems only necessary for us to allude to the additions to the present one. For instance, the chapters on the dietetic and hygienic treatment of dyspepsia have been very much amplified, and there is a most valuable appendix containing an account of some experiments of Dr. Leared's to determine the cause of heartburn, and investigations upon the effect of various kinds of charcoal in absorbing gastric and intestinal gases, and thus relieving flatulence. We may add that our French brethren will be enabled to profit by this excellent and exhaustive work, a translation having been just made by M. Vaucher.

WEDNESDAY, APRIL 11, 1866.

SCEPTICISM AND CREDULITY IN PHYSIC.

THE inquiring spirit of the age has overthrown some of what were once considered the bulwarks of Medicine, and opinions once stoutly maintained, have either been spontaneously abandoned or have been controverted by the results of experience and observation. It cannot be denied that the excessive and almost indiscriminate bleedings, sometimes recommended and practised by our immediate ancestors, were often unnecessary and probably injurious; and even with the excellent work of the late Mr. TRAYERS as a guide, it must be admitted that the efficacy of mercury in the cure of inflammations is more than doubtful. As it is not our province to dogmatize on questions which are still on their trial, we do not assert that our forefathers were altogether wrong in employing active measures in the treatment of the diseases they encountered in their day; nor do we proclaim that many practitioners of the present day are altogether right in treating the therapeutic notions of their predecessors as contemptible emanations of ignorance and prejudice. We believe, indeed, that the mortality in recent times from

acute diseases is less than it has been in former periods in this country; and this result may be, and probably is, due to the more guarded and cautious adoption of lowering measures by our modern practitioners; but is it equally certain that the class of asthenic diseases has been diminished in number, or its fatality moderated? We are quite aware that under the present improved methods of diagnosis, many diseases are now described which formerly escaped detection, and therefore we do not assume that such affections as Bright's disease, bronze-skin disease, fatty degeneration of the heart, trichiniasis, and many others, are really new, although they have been described and individualized in comparatively recent periods; but on the other hand, we have very strong doubts whether the practitioners existing at the commencement of the present century, were familiarly acquainted with Asiatic cholera, or epidemic influenza, or diphtheria, or even whether they were acquainted with the typhus and typhoid forms of fever, such as they are described and known in Great Britain in the present day. We say in Great Britain, because we are not sure that the distinct existence of typhus and typhoid fevers is clearly recognized and generally admitted even in Ireland at the present moment.

The above remarks, however, are merely introductory, and are made to explain what appear to us to be some of the causes of the opposite extremes of scepticism and credulity prevalent among the existing generation of practitioners and patients. The student who turns to his Medical Dictionary or his Cyclopædia, and finds a stereotyped plan of treatment laid down for every disease, and who then, in attendance in the hospital wards, finds that the precepts given in books are never, or scarcely ever, followed in practice, naturally begins to doubt the efficacy of all medication whatever; and the practitioner who may have begun with a faith in his art, finds his idol rudely shattered by the discovery he too often makes that diseases get well, or patients die, under any or every treatment, or under no treatment at all.

But strangely enough the scepticism of the Profession is more than counterbalanced by the credulity of the public, who seem to cling with the utmost tenacity to any system of falsehood and quackery, in proportion as legitimate medicine confesses the imperfection of its ministrations. The physician who would plainly tell his hypochondriac or hysterical patient that there is very little the matter, and that mental repose or mental activity, as the case may be, is the only necessary remedy, will probably be regarded as ignorant and incapable; and he who would plainly announce that a cancer cannot be cured, or that a fever will run a certain periodical course, with or without the interference of medicine, would probably be regarded in the same light, and recourse would be had to the pill-vendor, or the cancer-curer, or the homœopathic quack, each of whom boldly pretends to do what scientific medicine confesses its inability to accomplish.

Viewed merely in a psychological light, it is perhaps

rather a source of consolation than otherwise that human beings suffering either from imaginary maladies or from affections generally regarded by the Medical Profession as hopeless, should believe that a cure may be effected by HOLLOWAY'S ointment, or MORRISON'S pills, or by the homœopathic globules, just as hundreds and thousands of mothers in the lower (and perhaps the upper) classes believe that measles is cured by the administration of saffron, which is sold universally in the chemists' shops for that purpose. But when we class together the pretensions of HOLLOWAY, and MORRISON, and HAHNEMANN, we do so for the purpose of observing that the homœopathic quackery is really the worst of the three, because the two former pretenders are avowed quacks, and profess boldly that their nostrums cure all diseases---a proposition which, whether true or not, is at any rate intelligible in its language; but the disciples of HAHNEMANN envelope their fancies in a mystical and quasi-scientific phraseology, which, while it imposes upon the uneducated and the half-educated, appears at first sight, even to the scientific mind, to express some important truths. It is quite intelligible that in the scheme of Providence remedies may have been provided for all the diseases to which mankind is liable, but the fatal objection to this dogma is that the data on which it is founded are not true, or at any rate that they are so few in number, and so imperfectly substantiated, that they are quite worthless. On the other hand, nobody pretends to deny that castor-oil will open the bowels, that opium will cause sleep, or that juniper will act on the kidneys; and even the most bigoted opponent to, or disbeliever in, physis will scarcely dispute the fact that intermittent fever is generally cured by the administration of quinine, or, to make our proposition perfectly logical, that the administration of quinine in intermittent fever is found so frequently to be followed by successful results that the sequence of cause and effect is pretty generally admitted.

Scepticism in Medicine, on the one hand, and credulity as to the action of drugs on the other, are both in great measure to be attributed to imperfect perception, on both sides of the argument, of the real nature of disease and the real domain of therapeutics. The sceptics, while they doubt the efficacy of all medication, should reflect whether the discordant results they observe are not due to essential differences in the character of disease in different constitutions and at different seasons, times, and places; and the credulous should know that many of the supposed cures wrought by the quacks are imaginary, and that the statements made by these gentry are almost all mendacious. Even when the facts may be truly stated, the reasoning is false, as, when a homœopath tells us that he has cured a pleurisy or a pericarditis by the administration of a globule of some inert drug. The disease, indeed, may have disappeared, in one or two exceptional cases, under such circumstances, but the cure was due to Nature, and not to the globule, which had actually no share at all in the result.

Notes on Current Topics.

VERDICTS OF *FELO DE SE*.

THE verdict of *felo de se*, under any circumstances, is a poor and pitiful mode of wreaking vengeance upon the remains of a human being who has passed beyond the reach of the law, and the only result can be to inflict pain upon the feelings of survivors, who perhaps are sorrowful enough at the loss of a relative, or, it may be, are already humiliated by the sins or the misfortunes which led to the melancholy event. But if such a verdict is to be returned by a jury at all, it should only be after a most careful investigation of all the facts, guided by at least some elementary knowledge of the principles of psychological science. These remarks have been called forth by an inquest lately held in London upon the remains of a man named Villers, who guillotined himself in Bouvere-street, and on whom a verdict of *felo de se* was returned, upon no other grounds, it would seem, than that the suicide exhibited great mechanical skill, self-possession, and ingenuity in the mode by which he destroyed himself. The *Pall Mall Gazette* has been, we believe, the only influential London journal which has protested against this absurd and unjust verdict, and Dr. Forbes Winslow, in a letter addressed to that periodical, adduces the fact of a lunatic having committed suicide by crucifying himself in a most ingenious manner upon a cross which he had manufactured for the purpose, and to the construction of which he had devoted several years. Dr. Winslow very properly and very truly remarks that design, method, great cleverness of a mechanical kind, self-possession, and cunning are constantly observed among the insane afflicted with suicidal monomania.

RUMOURED ABUSE OF PATRONAGE AT THE HORSE GUARDS.

It is said in some of the political, as well as in the medical journals, that a small piece of jobbery in the Medical Department of the Army has been, or is about to be, perpetrated in reference to a vacant appointment in one of the regiments of the Guards. At the outbreak of the Crimean war, when medical officers were required for active service, and when the supply fell considerably short of the demand, several gentlemen were induced to enter the medical service of the Guards, on the distinct understanding that the promotion would be *regimental*, that system being in operation in the department of the army in question. Lately, however, the rule has been set aside on the occasion of a vacancy, and the medical officers who joined the respective regiments on the understanding referred to, find that they have been betrayed, and that in a particular instance it is anticipated that promotion will go in the brigade, and not in the separate regiments. What makes the matter worse, is that it is said the step in question is taken by the Commander-in-Chief on personal grounds alone, and that its effect, if carried into operation, is to benefit, at the expense of the other medical officers, a gentleman who happens to be the son of a surgeon who was in the Duke's late regiment. We hope that the rumour to which we allude is unfounded, or; at all events, that the intention of deviating from established rule in the case of one favoured individual will not be fulfilled, for such an abuse of patronage cannot fail to increase the prevailing discontent among the medical officers of the

army in general, who ought to be conciliated rather than affronted at the present moment, when the best men of our profession are invited to enter the service.

QUACK TITLES.

We beg to direct the attention of our readers to a letter under the above head in our present number.

We are glad to be able to say that one result of the article referred to by our Correspondent has been the suppression of obscene quack advertisements in some numbers of two journals which we have recently seen, and which were adverted to by us in the article above mentioned—the *Cork Constitution* and the *Cork Daily Herald*.

We hope soon to be able to say as much for the *Irish Times*, which ought to be as respectable a journal as those already named.

Some of our readers will recollect that we had occasion to bring under their notice last year the conduct of another paper published in Dublin (the *Commercial Journal*), and that subsequently we published a letter from its editor announcing his intention to stop the quack advertisements as soon as his then existing contracts for their insertion should have come to an end.

With regret we are obliged to state that this promise has not been adhered to, and we feel compelled to inform the profession of the fact that they may shape their own conduct accordingly.

We are determined to use the legitimate power of the press to put down such a continued insult to religion, morality, health, public decency, and domestic purity, as is necessarily involved in the continuance of these filthy and dangerous advertisements, which our readers will not fail to observe are inserted without scruple by journals, not only most orthodox in the religious department, but even inserting articles and letters on vexed questions of religious doctrine, while thus neglecting one of the weightier and more practical matters of the law, "let no filthy communication proceed out of your mouth." Our Correspondent has made an unintentional mistake in stating that we advised political journals to refer to the Medical Register only for the names of qualified practitioners. What we advised was to refer to that Register *and* to the "Publisher's Catalogue." We are aware that a qualified man, unregistered and retired from practice, *may* write a *bona fide* medical work. In such case it will be found in the "Publisher's Catalogue;" but, as a matter of every-day fact, the name and work of a qualified *practitioner* will in 999 cases out of 1000 be found in both records.

THE SICK POOR IN ENGLISH WORKHOUSES.

THE Poor-law Board has at last begun to move in answer to the appeals so frequently made in reference to the shameful treatment of the sick poor in the metropolitan Workhouses. It has lately determined to instruct Mr. H. B. Farnall in conjunction with Dr. Edward Smith, now the Medical Officer of the Board, to inspect the infirmary wards of all the London Workhouses, and to inquire into and report upon the existing arrangements for the care and treatment of the sick poor. It appears that the Board has also requested these gentlemen to suggest such remedies for any existing evils in the Workhouses as they may think necessary to improve the condition of the inmates. We are very sceptical as to the results of this inquiry, considering that the Poor-law Board knows already perfectly well

the nature of the abuses which have existed under its very eyes, but it is just possible now, that the public opinion has taken a turn in favour of the poor, that the Board may do something. In the meantime, we understand that the following document has been lately forwarded to the President of the Poor-law Board, as expressing the opinion of some of the leading members of the Profession as to what is necessary for the better treatment of the sick poor in the Workhouses:—

Having been requested to express an opinion of the principles which should guide any efforts to improve the State treatment of the sick poor in workhouse infirmaries, we beg to state that any scheme in order to be satisfactory should, in our judgment, be based upon the following principles:—

I. The sick poor should be separated from the able-bodied paupers, and their treatment should be placed under a distinct management.

II. In lieu of sick wards annexed to each workhouse, consolidated infirmaries should be provided, where the following rules of hospital management should be adopted under skilled supervision. They are those generally accepted in this and other European countries:—

1. The buildings should be specially devised for the purpose of suitable construction and on healthy sites. The rules laid down by the Barrack and Hospital Commission may be consulted with advantage on this subject.

2. Not less than 1000 (and for particular classes of cases 1200 to 1500) cubic feet of air should be allowed to each patient.

3. The nursing should be conducted entirely by a paid staff, and there should be not less than one day-nurse, one night-nurse, and one assistant-nurse for each fifty patients.

4. There should be resident medical officers in the proportion of not less than one for each 250 patients.

5. The medical officers should not have any pecuniary interest whatever in the medicines supplied, nor should they be charged with the duty of dispensing them.

6. A judicious classification of patients should be observed: the epileptic and imbecile, the acutely sick and the aged and infirm being treated in separate wards.

7. The aged and infirm, the chronically sick and the convalescent, should be provided with day-rooms separate from the dormitories.

George Burrows, M.D.; James Clarke, M.D.; Wm. Fergusson, William Jenner, M.D.; James Paget; Edward Sieveking, M.D.; Thomas Watson, M.D.

TRICHINOSIS.

VIRCHOW says that a kind of natural cure of trichinosis is the encysting of the trichinae. When shut up in a cyst, the wanderings and further development of the animals are arrested. They become imprisoned, and show no signs of existence in their then feeble state of vitality. Art can do nothing here in the cure. The attempt to assist the encysting process by giving phosphates and acetic acids is founded on a false idea; for it is not the calcification of the cyst, but the formation of it, which is essential. If the patient live long enough to allow of the formation of the cyst, in all probability the trichinae will not afterwards destroy his life. It is possible, he adds, that some remedy may be found which will kill the trichinae without destroying the patient; but assuredly none such has as yet been discovered. The most dangerous guests are the muscular trichinae, and to find a remedy to kill them would indeed be of the highest benefit. In the meantime, we must remember that the intestinal trichinae produce the brood of young animals which wander through the body into the muscles. The longer, therefore, these breeding animals are allowed to remain in the intestines, the greater will be the progeny set free in the body, and therefore the more destructive the disease.

Hence it is of the highest importance to attempt to remove at once the breeding animals from the intestines by emetics and purgatives. [We are not aware whether the destruction of the trichinæ in the muscles has ever been attempted by the galvanic current; but the attempt, *a priori*, seems worthy of a trial. Such a shock as would be harmless to man's muscular fibre might, perchance, destroy the feeble organism of a trichina.—*Editor British Medical Journal*.]

RETROSPECT OF THE MEDICAL JOURNALS.

APRIL 7TH, 1866.

THE *Lancet* reviews the report of the Army Medical Department for 1863. Some of the papers therein contained are valuable in a sanitary and preventive point of view, but exception is very justly taken to the fact that the question of therapeutics and the medical treatment of disease is altogether overlooked.

Our contemporary alludes to the inaugural address by Dr. Watson, on the occasion of his being elected for the fifth time to the President's Chair at the College of Physicians: in it he intimated his intention of withdrawing after this year from the office to make room for a younger hand. This conduct is contrasted with that of the governing body of the College of Surgeons.

"The annual election of members of Council will take place in three months, and we shall hope to see some new members elected who will strive to follow the progressive policy of their brethren of the College of Physicians, instead of the uniformly obstructive measures which have hitherto obtained with the governing body of the College of Surgeons. Should they fail in obtaining a new charter, they might at least prevail in enforcing the provisions of those already existing—viz., the election of President from among non-examiners, the appointment of Examiners from among the Fellows at large, and the *bona fide* election of these Examiners every five years, all of which regulations are at present evaded."

The system of nursing by lady sisters and nurses, which has proved so advantageous in King's College, St. Thomas's, University College, and the Great Northern Hospitals, is to be tried in St. George's, Charing-cross, and the Middlesex. This journal has already alluded to the introduction of the system in Dublin into Dr. Steeven's Hospital.

A good deal of dissatisfaction is very properly evidenced, by those interested in the matter, in reference to the appointment of a Surgeon to a Regiment of Foot Guards; hitherto these appointments have been made by *regimental* promotion, but now an attempt is being made to make it by *brigade* promotion, evidently with the object of bringing forward a favourite.

The cattle plague returns show a marked decrease in the number of cases.

According to the report of the *Lancet* Commission, the Infirmary of St. Margaret's and St. John's, Westminster, is in a more favourable condition than many others, but little credit is to be given to the governing bodies of these institutions, it is to their excellent and self-denying Medical Officer, that many of the improvements are to be attributed.

The exhibition of obstetrical instruments at the *Conversazione* of the Obstetrical Society seems to have been a complete success.

It is a curious fact that at the same time there were in London Hospitals three cases in which amputation at the hip-joint was successfully performed; one of these, under the care of Mr. Erichsen, we have already referred to; the other two have occurred in St. George's, one in the practice of Mr. Holmes, the other in the practice of Mr. Lee, for the removal of a fibroid recurring growth, and for old disease of the hip. A description is given of an artificial limb made for one of the cases by Mr. Gumpel, but it is a mistake to say that it is the first time such a

thing has been attempted. Chassaignac in Paris had one constructed for a patient of his. It is a model of mechanical ingenuity; the movements are regulated by those of the opposite limb.

The *Medical Times and Gazette* recapitulates the report of Dr. Lankester, the Coroner for Central Middlesex. It is to be regretted that infanticide is on the increase, as it is to be expected this unnatural crime is perpetrated in the majority of instances by domestic servants, we rarely meet with it in the class of prostitutes. *Apropos* to this subject, we find in the *British Medical Journal* a paper by Dr. Paterson on the causes which tend to endanger fetal life during labour, chiefly in their reference to cases which might be the subjects of medico-legal inquiry; the paper will be read with avidity by the lawyers.

There is in the *Times and Gazette* a very able article on Ozone, describing different methods for its preparation, &c.

A successful case of the Caesarian section has occurred in the practice of Dr. Greenhalgh, at least as far as one can judge at present. The patient was operated on March 29th, and was doing well on the 4th April. What makes this case the more interesting is the fact that she was rendered completely insensible to pain by local anæsthesia produced by Dr. Richardson himself. All the journals of the week give the details of this case.

Mr. Hutchinson's admirable lectures on "Rare Forms of Fractures and Dislocations" are continued. He alludes frequently to the writings of Professor R. W. Smith.

Several cases are related of congestion and sweating with lachrymation confined to one side of the face in connexion with epileptiform symptoms. We are inclined to trace these symptoms to lesion of the sympathetic which accompanies the internal carotid to the brain, and which, when interfered with, produces dilatation of the vessels and consequent cerebral congestion.

Dr. Brown calls on the Editor of the *British Medical Journal* to apologize to him for his review of the pamphlet published by the former, and which is so likely to damage the cause of the Naval Medical Officers.

In their ignorance of the condiment furnished by mushroom, our French neighbours have discovered a curious mares' nest; it is in connexion with the late case of summons for the adulteration of articles of food:—

"CAT-LIVER SOUP.—The French journal, *Les Mondes*, has a version of the 'Liver Catsup' tale. It tells us that in a large eating house (*établissement alimentaire*) in London, there is made daily an enormous quantity of a soup which is very popular, and is made of the half putrid livers of cats."

STATISTICS OF PARISIAN HOSPITALS.

STATISTICS show that there have been in Paris hospitals, during the month of February, 597 accouchements, and 53 deaths: in the Hôtel Dieu, 104 accouchements, and 1 death; in the Lying-in Hospital, 74 accouchements, and no less than 30 deaths! The frightful mortality which has so long distinguished the Maternité is arresting the attention of authorities. The statistics are as follows:—

	Accouchements.	Deaths.
Beaujon	33	0
Hôtel Dieu	104	1
Saint Louis	77	1
Charité	42	1
Necker	30	1
Pitié	53	3
Cochin	34	3
St. Antoine	41	5
Cliniques	56	8
Maternité	74	30

M. Lefort has lately given some interesting statistics, based on a consideration of 1,800,000 accouchements. Of 888,312 women confined in the Paris hospitals, 30,594, or 1 in 29, died. Of 934,781 women confined in their own houses, 4,405 died, or 1 in 212. The cause of the great mortality in hospitals is puerperal fever.

Correspondence.

WE are not to be assumed to agree with the views of our Correspondents whose communications we insert for the purpose of affording opportunity for the enunciation of all shades of opinion in things medical. Our revision of letters is, therefore, confined to the removal of statements or expressions which we consider unsuitable or irrelevant to the subject in hand.

POOR-LAW MEDICAL REFORM AND VACCINATION:

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I shall feel obliged by your allowing me, through the medium of your columns, to inform the Poor-law Medical Officers, and I may say the profession generally, for nearly all medical men are vaccinators, that the Vaccination Bill will not go into Committee before the first Wednesday after Easter, time amply sufficient for every medical man in the kingdom to communicate with his Member of Parliament. I have sent a copy of the amendments mentioned by me in former communications to every Member of Parliament, and have written private letters to about twelve gentlemen in the House. From communications already received, I believe it is intended to permit certain alterations to be made in the Bill, and perhaps Government may consent to pay a portion of the fees; but unless that portion be specially appropriated to the medical men, it will only be relieving the poor's-rate without benefitting the vaccinator. The Bill will require careful watching, otherwise it will slip through Committee without being materially amended.

The general question of Poor-law Medical Reform must stand over until after the General Reform Bill has been disposed of.

Allow me to tender to Mr. Prowse of Amersham the best thanks of the Association for the exertions he has made in raising the large sum of £92 18s. which he has forwarded to me, and it is now in the bank to the credit of the Association.—I am, &c.

RICHARD GRIFFIN.

12, Royal Terrace, Weymouth, March 24, 1866.

The following subscriptions have been received since the last publication:—

Barton and Turner, Caistor, 10s.; Ray, E., Clerkenwell, St. James's, £1 1s.; Wyer, O. F., Nuneaton, 10s. 6d.; Greenwood, Major, St. Leonards, Shoreditch, 10s.; Willis, R., Tavistock, 5s.; Evans, M. G., Narberth, 10s.; Congdon, W. G., Penzance, 5s.; Smith, W., M.D., Weymouth, £1 1s.; Hanham, F., Bath, 10s.; Hinnell, E. J., Thingoe, 5s.; Morris, R. T., Wigan, £1; Green, H., Loxden and Winstree, 10s.; Tys, D. F., Blandford, 5s.

By Mr. Prowse:—

QUACK TITLES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Now that the subject of quackery is likely to obtain some notice through the instrumentality of your excellent journal, I trust the turbid waters having been stirred, the wave may not be allowed to subside till all impurities be removed, and the clear stream of legitimate medicine permitted to flow on in its rightful course, unsullied by the impure and obscene dregs which, too long tolerated, have at length served to render the clear fountain a very Stygian lake!

Following the course pursued in your leading article last week, and bearing in mind the words of the poet—

“Plurima felix
Paulatim vitia atque errores exiit omnes,
Prima docens rectum sapientia.”—*Journal*.

I shall endeavour to “teach what is right” concerning the

subject alluded to; and first, as to the author of the “Diseases of Women,” I have to remark it is only *one* of the many guises assumed by that individual; and as there seems to be some doubt as to his *identity* (and no wonder, having as many forms as the Lernaean Hydra of old), I trust you will forgive me adducing a few examples derived at random from some old publications. Having had my attention drawn to this individual more than eight years since, I have since that time watched each curious metamorphosis; and I only regret, a short time since looking over some old papers, I burned those which contained his *larva* existence. Omitting therefore this stage, we find in the newspapers of 1858-66, the following varieties of titles assumed by this “Doctor” :—

“Given away to Nervous Sufferers.

“Dr. Smith has just published a free edition of 20,000 copies of THE WARNING VOICE, or PRIVATE MEDICAL FRIEND. A new work on the cure of nervous debility, loss of memory, dimness of sight, lassitude, indigestion, dislike to society, local weakness, muscular relaxation, languor, listlessness, depression, &c., which, if neglected, result in consumption, insanity, and premature death; with plain directions for perfect restoration to health and vigour. Sent post free to any address on receipt of a directed envelope enclosing two postage stamps. Address, Dr. Smith, &c.

“Consultation by letter without fee.

“Dr. Smith will, for the benefit of persons suffering from Nervous Debility, &c., on receiving a description of their case (enclosing a stamped directed envelope for reply), send his written opinion, with advice and directions for the most successful treatment and cure. Address,” &c.

(December, 1859.)

“A Boon to Nervous Sufferers.

“Given Away—26,000 copies of a Medical Book, for the benefit of nervous sufferers, sent post free, by the author, secure from observation, on receipt of a directed envelope enclosing two stamps—the PRIVATE MEDICAL FRIEND, a new work on the self-cure of nervous debility, loss of memory, dimness of sight, lassitude, indigestion, dislike to society, &c., which if neglected result in consumption, insanity, and premature death; with plain directions for perfect restoration to health and vigor.

“Every young man should peruse this excellent little work if he values his health, happiness, and peace of mind.”—*British Critic*.

“The true guide to those who desire a speedy and private cure. By Henry Smith, Esq.,” &c.

The above is extracted from a most respectable paper—the *Evening Packet*.

1864, a slight change is observed:—

“A Boon to Nervous Sufferers.

“Dr. Smith has just published a Free Edition of 20,000 copies of his valuable work, THE PRIVATE MEDICAL FRIEND (116 pages), on the self cure of nervous debility, loss of memory, dimness of sight, lassitude, &c. Copies may be had free by sending a stamped directed envelope to the author's residence.”

Then follows the “free consultation” clause as above.

(*Irish Times*, 1865.)

“Read the NEW MEDICAL GUIDE. A Physician, who has devoted fifteen years to the treatment of nervous debility, loss of memory, dimness of sight, lassitude, and indigestion, has published a new edition of the New Medical Guide (120 pages), containing his mode of treatment, with necessary instructions, by which sufferers may obtain a cure. Sent post free in an envelope to any address, on receipt of a directed envelope and two stamps. Address, Messrs. Smith,” &c.

Now we come to the strangest transformation of all—the *imago* or *complete state*. In 1866 we find—

“Just published, by the Author of the ‘Volunteer's Manual.’

“NERVOUS DEBILITY: Its Cause and Cure. An invaluable work on the cure of nervous debility, weakness, loss of appetite, indigestion, &c. Illustrated with cases in proof of the author's successful treatment. Free by post on receipt of two stamps. Address Dr. Smith, M.D.”

The last quoted advertisement is extracted from this day's

Irish Times, and leads me to the more legitimate subject I wish to touch upon at present. Can we form any opinion why this individual (and many others of the same stamp) should assume so many phases? why we first find him "Dr." (1854-8), then "Esq." (1859), "Messrs." in 1865, and lastly, at the present day, "Dr. Smith, M.D."? Now, Sir, I think the answer is obvious, when we recollect that, prior to 1858, there was no check to any man styling himself "Doctor," till the passing of the Medical Act at the close of that year, which undoubtedly then struck terror into the breasts of these wretches, therefore the descent to an "un-actionable Esq.;" but soon some amongst this vile fraternity began to assume the former style, irrespective of the pains and penalties of the at first dreaded enactment. But *nothing detrimental followed; nay, the very power the quack at first dreaded, was found to afford protection*, so that growing bold through impunity, they now assume every title of legitimate medical rank. Nor is it an easy matter to determine the true from the false; and with all respect, I think the observation in your article last week—that the editors of the daily press should look into the *Medical Register* before publishing advertisements touching on professional subjects, — though good in principle, will in practice be found very defective. To quote an instance, having requested a friend to supply me with the names of those professing to be medical men in my neighbourhood, I obtained a tolerably long list, divided into *vera et falsa*; on examination, I found amongst the latter, names of *true members of the profession*, who, not being Registered, did not of course appear (they having retired from practice. Now, Sir, had any of these gentlemen sent notice of a work for publication, and the editor not finding their names on the *Register*, I need not state the unpleasantness likely to result. I shall advert to one other phase of this subject and have done. Not long since I saw a case of *compound fracture of the tibia in a very bad condition*. On inquiring how the fracture occurred, I obtained the following history:—The man was proceeding home in the dusk of the evening, when he stumbled over a stone and fell into the ditch; on rising he was unable to walk or use the left leg, however he managed to crawl as far as a cottage on the road side, when the inmates advised him to send for advice, which was done, and the *simple fracture* put up in the usual way. Some days after, one of the young men of the family brought in a *notorious quack* who had the reputation of being a *clever bone-setter*, and this worthy proceeded to investigate the state of affairs. What his manipulation was, of course, I cannot positively state, but to mend matters he contrived to make the *simple a compound fracture*. The patient, when I saw him some days after, stated it was the *Doctor who first saw him that did so*, which surprised me much, as he was a most skilful and excellent surgeon in every way. On minute inquiry, however, I learned the truth as above stated, the poor man asking me not to say anything of the circumstance, as he was afraid to tell on the quack, he having such influence over the peasants in the neighbourhood. I think, Sir, taking this in conjunction with the fact that these wretches, when they have fleeced and emptied the pockets of their victims, having brought them *in extremis*, then send them to seek legitimate advice, should act as a most powerful incentive to every member of our noble and humane profession to at once "rise in arms," and for ever exterminate these wretches.

In conclusion, I think from what I have so feebly endeavoured to promulgate may be deduced—

1st. All medical men in practice or not should be obliged to Register.

2nd. In the words of the Medical Act, sec. 40:—

"Any person who shall wilfully and falsely pretend to be or take or use the name or title of a Physician, Doctor of

Medicine, shall, upon a summary conviction for any such offence pay a sum not exceeding £20."

This Clause to be put in force and not any longer to remain a "dead letter," such prosecution to conviction to be conducted by the Medical Council or such others as they may delegate to do so.

3rd. A remonstrance to be addressed to the editors of those newspapers admitting obscene advertisements.

4th. The name of the individual, whose "literary history" is traced above, be brought before the Medical Council, and treated by them as the Act above cited empowers them to do to those assuming the title of M.D.

Hoping, Sir, you will forgive my occupying so much of your valuable space, and trusting you will not let the matter drop till something definite has been effected for the good of the profession and the public in general, I remain faithfully yours,

JOHN S. A. CUNNINGHAM, L.R.C.S.I., L.K.Q.C.P.I.
Rathmines, March 24, 1866.

[We are glad to see from recent numbers of the *Cork Constitution* and *Daily Herald* that our late article has cleared their pages of the advertisements objected to by us. We hope soon to be able to say the same of the *Irish Times*.—ED. M. P. & C.]

ON NURSING THE SICK.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR:

SIR,—As one of your readers, I feel much obliged for your article "On Nursing the Sick," in the number for Wednesday last. That your remarks were not only called for, but well-timed, received a melancholy proof from an announcement headed "Religious Enthusiasm" in the very same paper.

It appears—supposing that announcement to be exactly correct, and that it is not so I shall be very glad to hear—that thirty-one "Protestant" gentlemen deliberately rejected a large hospital endowment because of the annexed condition:—That the nursing should be placed under the care of the Sisters of Charity. No words could sufficiently condemn such conduct as this; coupled, as I suppose it would be, with a total neglect on the part of these "thirty-one Protestant gentlemen" to provide any substitute for the endowment so generously offered. However this reported occurrence bears you out in your strong recommendation to establish Protestant Nursing Sisterhoods or Training Institutions for Nurses, and I trust the matter will not be allowed to drop until we have several of them in full work in this city.

As some of your readers may not be "well up" in information respecting these associations, allow me to state a few facts which may act as incentives to further search on their part.

St. John's House, in London, an Anglican religious order, manages the nursing at King's College Hospital. The hospital pays the "House" £1000 a year, and in return is provided with all the female domestics, twenty-six nurses, a number of probationers in training, and six Lady Superintendents. This system has lasted for more than seven years, and has worked very well. The "House" is, as I have observed, a religious society. All its members must be members of the Church of England; they are not under "vows," and, practically, they are free to go or stay as they please.

The rules of this society, which I have read, were in great part drawn up by the late Dr. Todd of London, brother to the Rev. Dr. Todd, S.F.T.C.D., and were submitted to, and obtained the approval of, the then Archbishop of Canterbury (Sumner) and of the Bishop of London. It is with these nurses the present Archbishop of Dublin was so much interested.

University College Hospital has been nursed since 1860 by the ladies of All Saints Home, a religious order in connexion with the famous church of that name in Margaret-street, London. St. Thomas's Hospital is nursed by the Nightingale Training Institute, which is a secular body, and sprang out of the nursing exertions respecting our soldiers in the Crimean war.

Lastly, there is in Liverpool a "Nurses' Training School," which is a religious society, but is not confined to members of the Church of England. It is said to be very successful in its operations, which embrace hospital, district, and private nursing.

This institution was founded, I believe, in 1862, and received the support of wealthy Liverpool merchants. A sum of £4461 was raised by donations, and annual subscriptions were offered to the amount of £988. Under its management Liverpool is divided into eighteen districts, and by the last report (1866) I see that it nurses the Royal Infirmary, provides a staff of twenty nurses for the above-mentioned "districts," and has about fifteen nurses available for private families.

During the last year Messrs. Longman have published a full account of this institution in a small volume entitled "Organization of Nursing," to which Miss Nightingale has added an Introduction and Notes. It is published at 2s. 6d., and I can heartily recommend it to your readers. In conclusion, let me again thank you for your leading article, and allow me to hope that you will not let the subject drop.—

Yours truly, MEDICUS.

Dublin, April 6, 1866.

DISPENSARY SALARIES IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—The following table taken from the "Poor-law Returns" will serve to indicate the relative standards of the dispensary salaries in the county Cork in 1855 and 1863. It may be perceived that, whilst in the large proportion of the unions, a progressive spirit of liberality has been displayed by the poor-law guardians, the contrary characteristics have continued to be exhibited in some exceptional divisions despite of all reasonable remonstrances, which proves that nothing short of *Legislative interference* will be sufficient to force "some boards" to relinquish their narrow-minded policy and sordid grounds of selfish opposition to demands, in which not only the interests of medical officers are concerned, but also those of *suffering humanity*, &c. &c.—Your obedient servant,

A PHYSICIAN.

Kinsale, April 6, 1866.

It is proposed for the consideration of the Poor-law authorities, that six hospitals, each containing a thousand beds, shall be erected in London for the purposes of the sick poor of the metropolis. These hospitals will be paid for by the ratepayers generally; but will be placed under an uniform management. Their superintendence will be vested in paid officers, who will be responsible, not to the ratepayers, but to the Poor-law authorities. The treatment of the pauper sick will there be conducted as the treatment of the sick is conducted in ordinary hospitals; and so that the cruel and miserly thriftiness of Guardians will no longer be able to step in between the sick pauper and his requirements. It is proposed that, at the head of this great scheme, shall be placed (as in Paris) a lay director, and under him two medical superintendents who shall direct and be responsible for its proper working. And, besides this, each hospital will be amply supplied with its own medical staff and nurses; and will be in itself a model hospital, furnished with all the modern provisions required for the treatment of the sick.

The University of Leyden has just elected three medical professors, Heynsius, Zayer, and Boojard.

VESTIGES OF MAN IN KENT'S CAVERN, TORQUAY.

MR. PENGELLY, in a lecture lately delivered at the Royal Institution of Great Britain, states that in this cavern nothing like an entire, or even a considerable portion, of a skeleton has been found. The principal identifiable remains are teeth, amongst which are those of the cave-bear, cave-lion, cave-hyæna, fox, probably more than one species of horse, ox, several species of deer, the tichorhine rhinoceros, and the mammoth. The hyæna, and, after it, the horse and rhinoceros, are the most prevalent forms. The relics of the mammoth—tusks and teeth—are those of very young animals. Without including doubtful specimens and mere chips, about seventy "flint" implements have been found. Like the bones, they are least numerous in the uppermost foot or "level" of the cave-earth. Some are of a light grey, others of a cream colour, or almost white; the latter, however, is apparently due to a natural or artificial metamorphosis, producing a more or less earthy texture, which rarely extends quite to the centre. The flint varies much in purity, and is sometimes more or less cherty. Some of the specimens are fragments only, others were found broken but with the parts lying in contact, whilst many are perfect. A few seem scarcely or never to have been used, and none of them present any traces of having been rolled. Some are highly wrought, but never polished; others seem to have been fashioned with but little effort or skill; whilst occasionally a rather large sharp splinter is met with, such as was probably struck off in fashioning a more elaborate tool. The most perfect implements are of two kinds:—flakes, flat or concave on one face, and carinated on the other; and oval implements, worked to an edge all round. Of the latter there are three specimens, all carefully made and well finished; one of them was found in the third, and two in the fourth, or lowest level yet excavated. The whetstones, of which there are two, are formed of hard, fine-grained, dark-green grit. The stone hammer is simply an ellipsoidal pebble of hard Triassic sandstone, which from the character of its protuberant surface, appears to have been held by the fingers applied at the extremities of its shortest axis, and used for breaking. The results of the exploration now in progress have confirmed most, and contradicted none, of those recorded by the earlier investigators. Compared with the previous evidence, that recently found is in a few cases defective, but never conflicting. The committee have found unquestionable human industrial remains, in the undisturbed cave-earth below the stalagmite, mixed up with the bones and teeth of the ordinary extinct cave mammals; but, unlike Mr. McEnery, they have not yet found any traces of *Machinivodus* nor of *Hippopotamus*; nor have they, like Mr. Godwin-Austen, met with any part of the human skeleton.

MEDICAL AND SURGICAL HISTORY OF THE LATE AMERICAN WAR.

GUNSHOT WOUNDS OF THE ABDOMEN.

OF 2707 gunshot wounds of the abdomen, so far recorded, 2164 were flesh wounds, and in 543 the peritoneal cavity was penetrated, or the abdominal viscera injured. Among the flesh wounds 114 fatal cases are recorded, which were mostly cases of sloughing from injuries of the abdominal parietes by shells. Of the penetrating wounds, the results have been ascertained in 414 cases, and were fatal in 308, or 74 per cent. The number of recoveries is unexpectedly large, but includes only cases in which the reports showed, beyond question, that the abdominal cavity had been involved. In many cases fecal fistulae were produced. They commonly closed after a time, without operative interference, re-opening at intervals, and then healing permanently.

Recoveries after wounds of the large intestines have been much more numerous than after wounds of the ileum or jejunum. No case has been reported in which it was

thought expedient to apply a suture to the intestines after gunshot wounds. Gunshot wounds of the *liver* were usually followed by extravasation into the abdominal cavity and rapidly fatal peritonitis. Of 32 cases in which the diagnosis was unquestionable, all but four terminated fatally. All the cases of gunshot wounds of the spleen reported were fatal.

Gunshot wounds of the bladder, when the projectile entered above the pubes or through the pelvic bones, have proved fatal, as far as the records have been examined. But there are many examples of recovery from injuries of the parts of the bladder uncovered by the peritoneum.

Several examples of recovery after protrusions of the abdominal viscera through gunshot wounds have been reported. In two cases, in which loops of small intestine issued, they were immediately returned and retained by means of adhesive strips and bandages, and the patients recovered with ventral hernia. The escape of omentum through wounds would not appear to be a very serious complication, for in many cases portions of protruding omentum have been excised, and the patients have, nevertheless, recovered promptly.

GUNSHOT FRACTURES OF THE PELVIS.

The records under this head include only the cases in which the abdominal cavity was not penetrated. So far, 359 cases are embraced in the report of Surgeon Otis. Recovery took place in 97, death in 77, and the result is still to be ascertained in 185. In 236 cases the ilium alone was injured, the ischium alone in 19, the pubes in 12, the sacrum in 32, and in 40 cases the lesions extended to two or more portions of the innominate. Very tedious suppuration in cases of injury of the pelvic bones commonly took place, and surgery could do but little except to facilitate the escape of pus and remove dead bone. The returns corroborate the observation of Strohmeier, that there is a great liability to pyæmia in these cases.

GENITO-URINARY ORGANS.

Of 457 cases of gunshot wounds of the genitals or urinary organs, so far recorded, and uncomplicated with fractures of the pelvis or penetration of the abdominal cavity, 37 had a fatal result. Surgeon S. W. Gross, U.S.V., reports a case where a conoidal musket-ball buried itself in the corpus cavernosum and became encysted. It gave no pain, and the patient refused to have it extracted.

UPPER EXTREMITIES.

Of the 21,248 cases of gunshot wounds of the upper extremities, the records so far are not sufficiently advanced to make accurate deductions.

DIALYSIS APPLIED TO TOXICOLOGICAL INVESTIGATIONS. (REFEIL.)

THE following are the results of the author's experiments:—

The presence of fatty matter is in some degree an obstacle to the separation by the septum.

The separation of the colloids and crystalloids is more rapid when there exists a considerable difference of temperature between the two liquids—*i.e.* that of the dialyser and that of the receiver, although the equilibrium is not long in re-establishing itself.

The presence of albuminous substances is a great obstacle, especially in such cases as the salts of copper, mercury, iron, lead, tin, &c. It is necessary in such cases to strongly acidulate with nitric or hydrochloric acid, and then to boil, separate the coagulum, and treat again with acidulated water, mix the two liquids, and submit them to dialysis.

The presence of albumen is of no consequence as regards the detection of the organic alkaloids, arsenious and arsenic acids, and the alkaline cyanides.

The separation of the organic alkaloids from such liquids as milk, urine, blood, bile, broth, &c., takes place very slowly, taken in some cases, five or ten days.

The presence of the organic alkaloids may be shown in the liquids dialysed by the potassio mercuric iodide.

Atropine, acetonine, daturine, solanine, and veratrine do not give reactions sufficiently characteristic to prove their presence.—*Year Book of Pharmacy.*

THE DETECTION OF BLOOD-STAINS BY THE MICRO-SPECTROSCOPE.

THE trial of Robert Coe for the murder of John Davies, at Aberdare, is remarkable, says the *Pharmaceutical Journal*, as the first case in which the micro-spectroscope has been employed to furnish evidence of the presence of blood-stains. The following is Dr. Herapath's evidence:—

Dr. Bird Herapath sworn: "I am a Fellow of the Royal Societies of London and Edinburgh. I practise as an analytical chemist and also physician. The hatchet produced was given me by Mr. Wrenn, and I carefully examined it. On the metallic portion I did not find any marks upon which I could rely. I removed the handle and experimented on thin slices of wood which I took from underneath the metallic ring. I examined those sections with a microscope, and found the majority of the stains were due to oxide of iron; some of them showed clotted blood; in some cases the woody portions had been infiltrated with the colouring matter of blood changed by the action of water. On some of the sections of the handle I found globules of blood, and by the micrometer I measured the size of those globules. I placed a section of the handle in a glass cell in which there was a fluid medium, and the blood-globules floated off into the cell, and by the measurement of these I could determine the size of the globules therein contained. These globules were exactly the same size as some globules from dried human blood which I purposely procured, and tested with the same apparatus in the same way. Finding this evidence of blood to be small, I obtained more numerous sections of the coloured surface of the handle of the hatchet, immersed them in distilled water, and obtained thereby a slightly coloured solution, which after filtering was ready for chemical tests, and for optical examination by the micro-spectroscope. I subjected this fluid to the action of light, and it had undoubtedly the properties peculiar to a solution of blood. When a solution of blood was examined in this instrument (instrument here produced) the fluid absorbed some of the rays of light, and thus altered the spectrum or rainbow. Within the green, and on the border of the yellow rays two dark absorption bands were produced by the blood fluid. Only one other substance would produce two dark bands—that is cochineal dissolved in ammonia, but the position of the two bands was different. The spectroscope alone would not enable me to readily distinguish between the two, but combined with chemical examination it would satisfactorily do so. From this optical test I was satisfied that the sections of the hatchet had been stained with blood, and by chemical analysis I also demonstrated it was blood. The combination of the three tests showed that the substance on the hatchet must have been blood."

Cross-examined: I should not like to say that the stains were those of human blood, but my opinion is that they were.

PREPARING FOR CHOLERA.

EDWIN KING, and other owners of property in Grosvenor-street, Islington, were summoned by Mr. William Mayes, sanitary inspector, for knowingly suffering to be occupied a front room on the basement floor, there not being an area three feet wide in every part from six inches below the floor of the room to the surface of the ground adjoining. There were other summonses against the defendants under the Nuisances Removal Act for England, 1855, for allowing the houses, the inhabitants whereof consist of more than one family, to be so overcrowded as to be dangerous to the health of the inhabitants. Mr. William Mayes said he is sanitary inspector. On the 22nd ult. he inspected the houses in Grosvenor-street, and found at No. 2A that the kitchen was used as a separate dwelling by a man, his wife, and two children. A death from fever had taken place in this house about six weeks since, and there was now one person in the house under medical treatment. The house is filthy. At No. 6, the kitchen was occupied by a man and his wife, and there was a bed and bedstead in it. At No. 7 the kitchen was occupied

by a mother and daughter, and there was a sofa-bedstead in the room. The house No. 8 was overcrowded, seven persons sleeping in a room, which only gave 123 cubic feet of air to each person. The house No. 11 was occupied by thirty-two persons—viz., six men, eight women, and eighteen children, seven sleeping in the front and five in the back kitchen. At No. 11A the house was occupied by thirty-six persons—viz., eight men, eight women, and twenty children, the front kitchen being occupied as a separate dwelling by one man, one woman, and four children. The back kitchen was occupied by one man, one woman, and two children; a child recently died in this room, and one that was then under Medical treatment has since died. The room is very damp, the drains are very defective, depositing the liquid soil in the passage, which saturates the partition and floor boards. Frequently the water flows under the bed. The first-floor front was occupied by one man, one woman, and six children. No. 15 was occupied by 33 persons—viz., five men, eight women, and 20 children. Here the front and back kitchen were occupied by three and four persons separately. No. 16A was occupied by 39 persons—viz., eight men, eight women, and 23 children; the front parlour being occupied by one man, one woman, and three sons, aged 9, 12, and 19; and the back parlour by one man, one woman, and four children. The whole of these houses contain eight rooms each, the largest of which is 12 ft. by 14 ft. by 9 ft.; the annual value of each is £30, but as they are at present let they are producing £65 each per annum. The basements of the whole of the houses are very damp; the drainage is defective, the yard being without any, the surface water in one instance flowing into the back doors, the water running down the wall, washing off the paper at the side of the bed. The houses generally are in a very filthy condition. The 32 houses in this street contain 528 men, women, and children. Eight of the above houses belong to Mr. Edwin King, and contain 239 men, women, and children. The defendants all said that they would remedy the evils complained of as soon as possible. The magistrate made orders for the abatement of the nuisances, and fined the defendants in sums varying from 10s. to 2s. 6d., besides ordering the defendants to pay the costs. Mr. Layton applied for fourteen other summonses of a similar description, which were at once granted.

NON-EXHALATION OF CARBONIC OXIDE BY PLANTS. (COREWINDER)

THE author has devised an apparatus, which enables him to estimate minute quantities of carbonic oxide in the atmosphere. By this apparatus, the author has investigated the question of whether plants really exhale, or not, carbonic oxide or other combustible gases. He arrives at the following conclusions:—

1. That there is no appreciable quantity of combustible gases in the atmosphere.
2. That none are evolved from putrefying dung or manures.
3. That none are to be detected in the gaseous products emanating from even the most odoriferous flowers.
4. That none are evolved from the leaves of plants, either by day or night, in sunlight or in shade.
5. That when a plant is submitted to the action of the sun's rays, in presence of a notable proportion of carbonic acid this gas is absorbed with rapidity, but the leaves exhale no trace of oxide of carbon.

These latter experiments were not made upon mutilated plants; they were made in the country, in the author's garden, upon plants living in a normal state.—*Year Book of Pharmacy.*

THE SMOKE NUISANCE.—In the House of Commons, on Friday week, Sir R. Peel drew attention to the nuisance arising from the smoke of furnaces in towns and country districts, and animadverted upon the great waste of coal, and the destructive effects arising therefrom to human life and health and to the vegetation in the neighbourhoods of large centres of manufacturing industry. Sir G. Grey said he had directed an inquiry to be made in the principal towns as to the means taken to enforce the law, and he had no doubt that the result would throw light upon the defects in the law and point the way to improvements, in which case he should be prepared to bring in a measure embodying such amendments as might seem to be advisable.

Meetings of Scientific Societies.

ROYAL.—March 22.—The following papers were read:—"On the Action of Trichloride of Phosphorus on the Salts of the Aromatic Monamines," by Dr. A. W. Hofmann.—"Notice of a Zone of Spots on the Sun," by Prof. J. Phillips.

GEOGRAPHICAL.—March 26.—"Observations on a Memoir recently published by M. Veniukof, on the Pamir and the Sources of the Oxus in Central Asia," by Sir H. C. Rawlinson.—Sir Henry said that the maps and itineraries of the anonymous author had been accepted by several Russian geographers as of undoubted authenticity, and the map founded on them and published in the *Journal of the Russian Geographical Society*, had been made use of in the compilation of the best recent maps of Asia, including Russian official maps and those of Prof. Kiepert of Berlin, and Stanford of London. So little known and yet so interesting, both geographically and politically, was the region under consideration, that if this elaborate manuscript were genuine it would be the most valuable contribution to our knowledge of Central Asia ever made; but if it was not genuine it was one of the most successful forgeries ever attempted in the history of literature. He had given great attention to the subject, and after considering the arguments on both sides, had arrived at the conclusion that the document was an elaborate hoax. The story of the active volcano, north of Srinagar, in a province which had now been almost as well surveyed as our own country, and where no volcano was ever known, and the impossibility of performing the journeys in the number of days stated by the author—as, for instance, the 120 miles between Srinagar and the Indus, through a mountainous and most difficult country, in two days, and the distance between the Indus and Kashgar in twenty-five days—were alone fatal to the authenticity of the narrative.

ROYAL INSTITUTION.—Jan. 19.—"On Radiation and Absorption with reference to the Colour of Bodies and their State of Aggregation," by Prof. J. Tyndall.—Feb. 23.—Sir H. Holland, Bart. M.D., President, in the chair.—"On Kent's Cavern, Torquay," by Mr. W. Pengelly.

STATISTICAL.—March 20.—A paper was read by Mr. S. Brown, "On the Statistical Progress of the Kingdom of Italy." Since the union, in 1860, of the various provinces constituting the new kingdom of Italy, considerable attention has been paid to the collection of Government statistics—a department being attached to the Ministry of Agriculture, Industry and Commerce, aided by Councils, in all the Prefectures of the kingdom. The last Census was taken on the night of the 31st December, 1861, when the population was found to be 21,704,000. At the rate of progress since observed, on the 1st of January in this year it is estimated to be about 22,300,000. The population is mostly agricultural, the largest cities being very inferior in numbers of inhabitants to the great cities and commercial towns in England. Florence will, no doubt, rapidly increase, as the seat of Government; but at the date of the Census it had only 114,000 inhabitants; Naples, 417,000; Turin, 180,000; Milan, 219,000; and Palermo, 186,000. A few leading facts were given to show the condition of the kingdom under each of the heads—Population, Army, Navy, Roads and Railroads, Telegraphs, Post Office, Friendly Societies, Products of the Soil, Commerce and Finance. Great activity prevails in extending the lines of railway to attract the traffic of the East to the Italian coasts of the Adriatic. The completion of the Mont Cenis tunnel and a projected Alpine railway over the St. Gothard are expected by the Italians to give them a large share in the transit of light goods and passengers when the Suez Canal is opened. The products of the soil of Italy—oil, wine, rice, cotton, silk—its vast tracks of unexplored mineral grounds, and thousands of square miles of land which only require scientific irrigation to render them the most fertile in Europe—open up a great future for her commercial enterprise, to which, under the new Government, the greatest attention is being given. The most difficult problem at present is the financial condition of Italy. Wishing, too, and perhaps, partly under the necessity of maintaining a large army at heavy cost relative to the present revenue of the country, Italians yet object to the corresponding sacrifices, though at present but lightly taxed as compared with other countries. The public debt is already £176,000,000, and it is advancing at the rate of

£8,000,000 to £10,000,000 a year. The only remedy is a large reduction of the army, or a much heavier taxation. It appears probable the Italians will choose the latter, which the increasing wealth of the country and development of its resources will render easier to bear.

SOCIETY OF ARTS.—March 21.—The paper read was:—"On Deer Forests and Highland Agriculture in relation to the Supply of Food," by Prof. Leone Levi.

ANTHROPOLOGICAL.—March 20.—The following papers were read:—"On Human Remains from the Thames at Kew," by Capt. A. C. Tupper.—"On the Brochs, and so-called Picts Houses of Orkney," by Mr. S. Petrie.—"Report on the Ancient Remains of Caitliness," by Mr. J. Anderson.

UNIVERSITY OF EDINBURGH.

THE DEGREE OF LL.D. CONFERRED ON PROFESSOR HUXLEY AND DR. RAE.

On the occasion of the installation of Mr. Carlyle as Rector of the University, amongst the gentlemen presented for the honorary degree of Doctor of Laws were two who were originally trained as members of the Medical Profession—Professor Huxley and Dr. Rae, the Arctic explorer. We subjoin the speeches in which Professor Muirhead recounted their claims to academical honour when presenting them to the Vice-Chancellor:—Professor Muirhead, in presenting Mr. Huxley, said: I present to you, Mr. Vice-Chancellor, as judged worthy by the Senate to receive the honorary degree of Doctor of Laws, Mr. Thomas Henry Huxley—(applause)—a Fellow of the Royal Society, Professor of Natural History at the School of Mines, and Hunterian Professor of Comparative Anatomy in the Royal College of Surgeons of England. Trained to the Medical Profession, Mr. Huxley became in early life an Assistant-Surgeon in the Royal Navy; and it was while serving in that capacity in one of her Majesty's ships, then engaged in a survey of the coasts of Australia and New Guinea, that he acquired his unrivalled knowledge of marine zoology, and vindicated his claims to be regarded as one of the most accomplished naturalists of the day (cheers). His appointment, on his return to this country, to the Chair of Natural History in the Government School in Jermyn-street, gave him an opportunity of turning his attention to palaeontological inquiries; and the results of his labour in that field are embodied in a series of valuable and most interesting papers descriptive of various extinct forms of animal life (cheers). As Hunterian Professor in the College of Surgeons of England, he has delivered several courses of lectures on the comparative anatomy of the vertebrata; lectures which, not less than his contributions to the transactions of learned societies, testify his remarkable perspicuity and his rare power of discriminating the relations of structure in complicated forms of animal life (cheers). Professor Muirhead, in presenting Dr. Rae, said: I next present to you, Mr. Vice-Chancellor, as also judged worthy by the Senate to receive the same honour, Dr. John Rae, a Fellow of the Geographical Society (applause), and a Graduate in Medicine of this University. Entering life in the medical service of the Hudson's Bay Company, he was soon afterwards transferred to its ordinary service, and before long attained the rank of one of its chief factors. In that capacity he had the command of several exploring expeditions in high latitudes—in the course of which, travelling sometimes in boats, sometimes in sledges, sometimes for weeks together on foot, he and his companions endured hardships and surmounted obstacles such as it had been the lot of few to encounter. On none of those occasions did Dr. Rae allow any opportunity to escape him of advancing our knowledge of the geography, meteorology, and natural history of the far north-west and frozen regions; and it is not to be forgotten that he it was who first obtained definite information of the fate of Sir John Franklin and his gallant comrades (loud cheers), and indicated the locality where three years later their remains were discovered by McClintock (applause). Very recently, Dr. Rae has been engaged on a Government survey of a telegraphic route from Canada to Vancouver's Island, over the wild country of the Rocky Mountains—an enterprise in which he completely succeeded, although the occupation of a considerable part of the route by savage tribes has caused the construction of the telegraph to be in the meantime suspended (cheers).

Medical Obituary Notices.

DEATH OF PROFESSOR DICK.

WE regret to announce the death of Professor Dick, Principal of the Edinburgh Veterinary College, which took place at his residence in Clyde-street. The deceased gentleman, who was a native of Aberdeen, died, after a three weeks' illness, of heart disease, at the age of 73. Professor Dick studied medicine at Edinburgh University, and was favourite pupil of the late Dr. Barclay. The Veterinary and Zoiatric College was founded by him in 1818; and, in consequence of the successful operations performed in it under the Professor's personal superintendence, it rose rapidly in public estimation, and attracted a large number of students. In 1823 the Royal Highland Agricultural Society of Scotland resolved to patronise it, and 1842 it was incorporated by Royal Charter. Professor Dick was Secretary to the Royal Physical Society of Edinburgh for many years; and on retiring from the post he was presented with a handsome silver claret jug, in testimony of the value of his services in that capacity. At the outbreak of the cattle plague, he was appointed Government Inspector of Foreign Cattle for the county of Mid-Lothian, in which duty he was assisted by Mr. Strangeways, Mr. Worthington, and Mr. Romanes. The system has worked so efficiently that no diseased animal has been suffered to enter the county from abroad. For a great many years, though with some intervals, he was an active member of our Town Council. His evidence before the Royal Commission to inquire into the cattle plague proved very valuable, and was of great service to the Commissioners. He was also for a long time Convener of the Edinburgh trades. In Burntisland he owned a considerable amount of property, and was at one time a member of the Town Council there. Mr. Dick was a man of strong natural abilities, and in his own profession of great acquirements and experience. In political and ecclesiastical matters, his views were somewhat extreme, and always expressed with no reserve and some roughness. He did not know fear, and had neither time nor skill for the mincing of words. But he was so honest, so truthful, so good-natured, and so free from self-seeking, that he had almost no enemies, and hearty friends everywhere. The figure and the name of "Willie Dick" were long conspicuous and familiar among us, and for long too he will be missed and mourned.—*Scotsman*.

J. WALLER MELSON, B.A. (LOND.), M.R.C.S.

OF late we have had to record the deaths of several members of the profession who have succumbed to diseases caught in the wards of our hospitals. It is with much regret that we have now to add another name to the list—that of Mr. J. Waller Melson, B.A. Lond., M.R.C.S., who died on the 22nd ult., at the General Hospital, Birmingham. Mr. Melson has for some time past acted as one of the resident clinical assistants at the General Hospital, and in performance of his duties he contracted the malady diphtheria, to which he fell a victim at the early age of 23 years. He was a most distinguished student of Queen's College, Birmingham, and graduated, with high honours in Physiology (2nd B.A. Exam.) in the University of London. His death, at the beginning of a career of much promise, has caused a feeling of great regret among the profession, and of deep sympathy with his father, Dr. J. B. Melson. Mr. Melson, we may add, is the second resident assistant at the General Hospital who has lately died of diphtheria.—*Lancet*.

SAMUEL HEMPHILL, Esq., M.D.

Died on the 17th of March, at his residence, Springhill, county Tipperary, Samuel Hemphill, Esq., M.D., aged 85, who, for more than forty years, stood in the first rank of his profession in Clonmel.

DR. JAMES PATERSON V. THE EDITOR OF THE GLASGOW MORNING JOURNAL.

THE now notorious Dr. Paterson, who figured so prominently in the great Pritchard trial, has again forced himself before the public, by appearing as the pursuer in an action of damages against Mr. Somers, the proprietor and editor of the *Glasgow Morning Journal*. The case was tried on Thursday and Friday last week before the Lord President and a jury, in the first division of the Court of Session. The action arose out of the following circumstances:—It will be remembered that Dr. Paterson was the medical attendant who saw Mrs. Taylor and Mrs. Pritchard during their fatal illness, and whose conduct in the case was much criticized and commented upon by the newspapers generally. In the *Morning Journal* for March 24th, 1865, three days after the arrest of Pritchard, there appeared a letter to the editor by "one who had much personal knowledge of Dr. Pritchard," and it is on this letter that Dr. Paterson founds his claim for damages, and of which he complains as libellous. Damages were laid at £3000. In the letter alluded to it was stated that the authorities had been led to take up proceedings against Pritchard through the receipt of an anonymous communication, and it was hinted that the writer of the letter was Dr. Paterson. This insinuation the latter gentleman declares caused him much anxiety, and damaged him considerably in his professional reputation and position, and on account of the injury sustained he now brings this action into court. Mr. Somers, in the witness-box, swore that he had no knowledge of who Dr. Paterson was when the discussion as to the guilt or innocence of Pritchard was being discussed, and that the letter complained of was not inserted with any intention to injure him. After a pretty lengthy trial, the jury on Friday found a verdict for Dr. Paterson, the pursuer, with damages of one farthing! We think that the result of this trial may have a good effect upon Dr. Paterson, and we hope that he will see the propriety and prudence of abstaining from any further litigation in connexion with the subject. By bringing this action he has again opened a discussion as to the manner in which he conducted himself in the Pritchard case—a discussion which, in our opinion, can only result in harm instead of good to himself; and we counsel him to allow the subject to drop into that oblivion to which it had been consigned, and from which he himself by these proceedings has for a time delivered it.

PEPSINE. (KOFMANN.)

A COMMISSION appointed to examine the pepsines sold by different makers have given the following conclusions:—

1. Pepsine is a body which possesses the property of coagulating milk, of dissolving fibrin, and other albuminous matters.
2. The quantity of pepsine necessary to coagulate a definite quantity of milk is dependent upon its purity. 25 milligrammes of pure pepsine suffice to produce this result in 100 grammes of milk heated to 40° C.
3. There are sold products under the name of pure or neutral pepsine which are neither pure nor neutral.
4. The addition of starch appears to exercise no conservative influence on pepsine.
5. Pepsine may be preserved pure, according to M. Kofmann, in gelatinous capsules, and, according to M. Domercq, when associated with equal parts of vegetable charcoal.—*Year Book of Pharmacy*.

ROYAL VETERINARY COLLEGE: TESTIMONIAL TO MR. TUSON.—On the 28th ult., a meeting was held at the College by the pupils of veterinary surgery to present Mr. R. V. Tuson, the teacher of Chemistry, with a testimonial "as evidence of their esteem for him, as well as a slight recognition of the able and energetic manner in which he had laboured in their behalf, and of his uniformly kind and gentlemanly bearing towards them." The presentation consisted of an address and one of Smith and Beck's binocular microscopes with numerous appliances.

ARMY AND NAVY MEDICAL SERVICE.

THE following interesting items are taken from the Appendix to the Report of the Admiralty Committee on Army and Navy Medical Officers' affairs.

The total number of candidates examined for the Army Medical Service since 1856 is 922. Of these, 713 were passed and 209 rejected.

The total number of candidates examined for the Naval Medical Service since 1856 is 569; of whom 389 were found qualified, 167 were rejected on account of defective professional knowledge, and 13 were found physically unfit for the service. In 1865, there were only 17 candidates, of whom 7 were rejected. In 1864, there were 49 candidates; of whom 21 were rejected; and in 1863, 63 candidates, 25 of whom were rejected.

The following return from the Colleges of Surgeons of London, Edinburgh, and Dublin, shows (besides other interesting facts) that the number of diplomas of the Dublin College is nearly double of what it was three years ago:—

Year.	London.	Edinburgh.	Dublin.	Total.
1845	348	101	354	803
1846	389	90	40	519
1847	355	76	38	469
1848	341	62	56	459
1849	401	86	45	535
1850	370	91	45	506
1851	404	88	45	537
1852	475	75	44	594
1853	526	110	56	592
1854	498	115	75	588
1855	549	144	89	782
1856	463	114	66	643
1857	517	139	74	710
1858	675	154	81	910
1859	583	102	78	763
1860	462	87	67	616
1861	493	94	70	657
1862	415	123	110	648
1863	457	123	113	693
1864	402	147	131	680

Since 1850, up to the present time, 117 medical officers have voluntarily left the army, at the following periods of service:—

Period of service.	Number.
Under 1 year	5
Between 1 and 2 years	22
" 2 and 3 "	21
" 3 and 4 "	18
" 4 and 5 "	16
" 5 and 6 "	9
" 6 and 7 "	7
" 7 and 8 "	6
" 8 and 9 "	4
" 9 and 10 "	3
" 10 and 11 "	1
" 11 and 12 "	1
" 12 and 13 "	1
" 13 and 14 "	1
" 15 and 16 "	1
" 16 and 17 "	1

This table shows that 48 out of the 117 resignations occurred before the end of the third year; and 82 before the end of the fifth year. After this date the voluntary resignations diminish very rapidly, and cease at the seventh year of service.

Since 1850, 137 medical officers have left the navy—19 surgeons and 118 assistant-surgeons. Of the assistant-surgeons no fewer than 63 (more than half) resigned before the completion of three years' service; 18 before the completion of one year; and 48 before the completion of two years' service. [This clearly shows how distasteful a naval life is to those who have not been brought up to it. The fact also tells dead against the opinion of Dr. Brown and others, that the present pay of assistant-sur-

geons of the navy is sufficient; and quite justifies the recommendation of the committee that it should be increased from 10s. to 12s. 6d. a day.—*British Medical Journal.*

TABES DORSALIS AND PROGRESSIVE GENERAL PARALYSIS.

IN Band xx. of the "Allg. Ztschr. f. Psychiat.," Dr. C. Urstphal published three cases in which the symptoms of advanced general paralysis were united to those of tabes dorsalis, in two of which after death he had recognized, by the microscope, grey degeneration of the posterior columns of the spinal cord. Since then he has had the opportunity of examining three cases after death, and has collected several analogous cases of other observers, so that he now reports on ten cases—three of his own, four of Hoffmann's, and one each by Joffe, Frerichs, and Meyer. Of these only two were not examined after death; the remainder presented—partly to the naked eye, partly to the microscope—the characteristic alterations in the spinal cord. In seven cases brain affection appeared early under the form of mental exaltation, even with epileptiform convulsions; in three, on the contrary, as intellectual weakness, coming on gradually, and increasing into the deepest apathetic imbecility; but in the former also imbecility appeared finally.

The disorder of motor power in this combined form presents at a certain stage a close resemblance to the complex symptoms of the so-called general paralysis. It might be very possible, therefore, that, in some cases at least, where the intellectual preceded the motor disorder, the grey degeneration of the posterior columns was secondary to a primary cerebral affection. But pathological anatomy has as yet afforded this theory no support, the opinion of Joffe and Erlenmeyer, who alone have at present declared themselves in favour of a secondary affection of the spinal cord, not being supported by post-mortem examination. On the contrary, that most important symptom in tabes—namely, the dependence in standing and walking on sight—is wanting in the usual picture of general progressive paralysis. It is, therefore, highly probable that the peculiar motor disorder of progressive paralysis does not arise, as in tabes, from disordered or abolished conduction in the nerves of sensibility; the often present dulling of feeling admitting very well of the explanation that the mental dulness of the patient prevents the perception of sensitive impressions; but they could, nevertheless, exercise a regulating influence over the usual order and sequence of movements, and thus make sight superfluous. The true cause of the motor disorder is, however, doubtful.

In seven cases symptoms of paralysis of the tongue were wanting; in two they were present, but not distinctly.—*Allg. Ztschr. f. Psychiat. and British and Foreign Review.*

ACTION OF DIASTASE ON STARCH.

THE following conclusions have been arrived at by M. Payen, after elaborate experiments:—

1st. That diastase exercises a saccharifying action on dextrine.

2nd. That this action is impeded by the presence of the glucose formed, but is resumed when the glucose is eliminated.

3rd. That the transformation of glucose into alcohol, during the alcoholic fermentation, presents no obstacle to the saccharization of the dextrine by diastase.

4th. That in favourable conditions of the action of diastase on starch, as much as 50 per cent. of glucose may be obtained.

5th. That it has not been possible to obtain 0.8791 of the starch used; but the maximum product has not exceeded 0.5271.—*Year Book of Pharmacy.*

GUADALOUPE. —Cholera has again broken out in the country districts. The medical staff has been augmented, and a commission appointed to make inquiries and point out a remedy for the epidemic.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.

ON Friday last, the 5th inst., at the quarterly meeting of the President and Fellows, Dr. Arthur Wynne Foot of this city was duly elected a Fellow. Dr. Foot is well known to the profession as a frequent contributor to its medical literature. He was one of the Commission recently sent to England by the Irish Government to investigate and report on the cattle plague. He is assistant reader in Anatomy in the University of Dublin, where he graduated B.A. and M.B. in 1862 and M.D. in 1865. He was admitted a Licentiate of the College of Physicians in 1862.

Licences to practise Medicine were granted to the following gentlemen during the months of January, February, and March, 1866:—

William Walsh, F.R.C.S.I. 1865, L.R.C.S.I., 1860, Kilmuckridge.

David Moore, M.R.C.S.Eng. 1859, House-Surgeon, Belfast Hospital.

Patrick Walter Tuite, L.R.C.S.I. 1865, Dublin.

Patrick Brady, L.R.C.S.I. 1865, county Cavan.

Joseph Irwin Welsh, L.R.C.S.I. 1865, county Donegal.

Samuel Henry Banks, L.R.C.S.I. 1865, Wicklow.

Charles Fryer, Lancashire.

Stephen McDermott, L.R.C.S.I. 1865, Roscommon.

John Fagan, L.R.C.S.I. 1865.

Edward Aloysius Stephenson, L.R.C.S.I. 1865, Kilkenny.

James Stirling, L.R.C.S.I. 1866, county Kilkenny.

William Longworth Watkins, L.R.C.S.I. 1866, Dublin.

Edward William Adrian, M.R.C.S.Eng., county Dublin.

To the following gentlemen Midwifery Diplomas were granted during the same term:—

Rowan Purdon, L.K.Q.C.P. 1864, Tralee.

David Moore, L.K.Q.C.P.I., Belfast.

P. E. McG'oin, M.D., Queen's Univ. 1863, county Mayo.

J. Irwin Welsh, L.K.Q.C.P. 1866, Ballyshannon.

John Fagan, L.K.Q.C.P., L.R.C.S.I. 1865.

Edward Aloysius Stephenson, L.K.Q.C.P., L.R.C.S.I. 1865, county Kilkenny.

James Stirling, L.K.Q.C.P., L.R.C.S.I. 1866, co. Kilkenny.

Wm. L. Watkins, L.K.Q.C.P., L.R.C.S.I. 1866, Dublin.

Medical News.

DR. DE SERE has just effected a new application of voltaic heat to surgery. At a white heat (1500° centigrade), produced by electricity, a platinum blade will cut the flesh through in an instant.

A SPRING OF NAPHTHA.—A Kertch paper announces that a spring of naphtha has been discovered in that neighbourhood. As much as 4000 gallons were obtained in twenty-four hours.

MR. SCHLEESING has succeeded in discovering an arrangement by which an intense heat, sufficient to melt iron, can be procured from ordinary gas. By Mr. Schleesing's plan a piece of iron weighing 400 grammes can be melted in twenty minutes.

M. JULES SIMON, in his new work "Le Travail," states that at Jelle and Rouen there are some women so saturated with intoxicating liquor that their infants refuse the breast of a sober woman. In the mountains of the Vosges the infants drink brandy.

ROYAL COLLEGE OF PHYSICIANS.—Dr. B. W. Richardson commenced the delivery of a course of six lectures at the above institution, on Wednesday last, on "Physical Researches in Pathology and Therapeutics." Members of the profession are admitted on production of their cards.

FRENCH EDUCATIONAL COMMISSION.—Dr. Demogeot and Dr. H. J. Montucci, Commissioners from the French Government, are at present in this country with the object of inquiring into the state of education in our universities, &c. Dr. Demogeot visited King's College and Christ's Hospital last week.

SANITARY LECTURES.—The course of sanitary lectures originated by the committee of the Ladies' Sanitary Association at Leeds has commenced. Dr. Greenhow has lec-

tured "On the Atmosphere," and Dr. Allbutt "On the Causes of Epidemics and the best means of Preventing them." Mr. Ikin has also lectured "On the Means of Preserving Health."

CHARING-CROSS HOSPITAL MEDICAL SOCIETY.—At the annual meeting of this Society, Mr. E. Sandwell, President, in the chair, the following gentlemen were elected office-bearers for the session 1866-7:—Hon. President: Dr. Hyde Salter. President: C. W. Calthrop, Esq. Vice-president: R. Bayley, Esq. Treasurer: J. G. Mackinlay, Esq. Hon. Secretary: W. P. Adams, Esq. Council: Messrs. Sandwell, Thorndicroft, Whitney and Wilkinson. Representatives of this Society serving on the Council of the Junior Medical Society of London: E. Sandwell, Esq., and C. W. Calthrop, Esq. After the election, Mr. S. S. White read the prize essay of the Society on Iritis. The prize awarded by the Society consisted of Aitken's "Practice of Medicine," together with two medical plates. The meeting then terminated with a vote of thanks to the retiring officers.

THE year before last Mr. Gregory obtained a select committee on the scientific institutions in Dublin, the object of which was to upset a Treasury report made in 1862, which recommended the abolition of the Museum of Irish Industry. But Irish interests were too strong, and Mr. Gregory's committee recommended its maintenance. Subsequently Mr. Bruce visited Dublin, and we gather from two minutes of the Science and Art Department the course which the Government has decided to take. It is proposed that the following departments of the Royal Dublin Society shall be wholly supported by public funds, like the corresponding public institutions in London, the society acting as trustees and being responsible for their administration:—the Museum of Natural History, including Mineralogy; the Botanic Gardens and Museum at Glasnevin; the Library of the Royal Dublin Society; Leinster Lawn, which should be made a public ornamental garden instead of remaining as at present a waste space between the National Gallery and the Museum of Natural History; the whole of the premises of the Royal Dublin Society, and the necessary staff of the society for conducting the business involved in the above-mentioned objects. The theoretical limitation of the amount of public funds to £5,500 annually is to be abolished and the annual grants necessary for keeping the above departments in efficiency will be considered on their merits and submitted to Parliament every year. It is thought that the Museum of Irish Industry should have a wider scope given to it than that of a School of Mines; that it should become a college for affording a complete and thorough course of instruction in those branches of science which are more immediately connected with and applied to all descriptions of industry, including agriculture, mining, and manufactures; that it should in this way supplement the elementary scientific instruction already provided for by the science schools of the department, and that it should assist in the training of teachers for these schools. To carry out these objects various propositions are made.

AN HYSTERICAL FREAK.—The fascination which the idea of depth exercises over some minds has been often observed, and some persons by no means generally nervous shun great heights, as they are conscious of an almost irresistible desire to leap into space. On Wednesday, a girl under treatment for hysteria in King's College Hospital was coming down the stairs which wind round the lofty walls of the vestibule; when she reached the level of the Surgical wards, she sprang over the ballusters, and was seen by Mr. Howells, the House-Surgeon, descending like a parachute, or rather as a parachute should, but seldom does, for she landed on her feet, and, except a slight strain of the ankle, was uninjured by her descent of more than twenty feet. She screamed when falling, but says that she now forgets all about it.

THE CHOLERA CONFERENCE AT CONSTANTINOPLE.—A proposal made by the French representative at the Cholera Conference to stop the sea communication between Hedpaz and Egypt in the event of another epidemic, has been adopted. The Porte, however, will not accept or enforce the measure, fearing an insurrection among the pilgrims.

MEDICAL SOCIETY OF LONDON.—The following gentlemen have been elected at the ninety-third anniversary meeting, as the officers and council for 1866-67. President:

Dr. Hare. Vice-Presidents: Dr. Gibb, Mr. Henry Smith, Dr. W. R. Rogers, and Mr. John Birkett. Treasurer: Mr. Marshall. Librarian: Dr. Head. Secretaries in Ordinary: Dr. W. Abbotts Smith, and Mr. Walter J. Coulson. Secretary of Foreign Correspondence: Dr. Julius Althaus. Council: Dr. Anstie, Dr. Broadbent, Mr. I. Baker Brown, Mr. Bryant, Dr. Cogswell, Mr. Victor De Méric, Mr. Du Pasquier, Dr. W. Tilbury Fox. Dr. Samuel Day-Goss; Mr. C. H. Rogers Harrison, Mr. Ernest Hart, Dr. James Jones, Mr. Henry Lee, Mr. Francis Mason, Dr. J. W. Ogle, Dr. James Palfrey, Dr. J. H. Paul, Mr W. F. Teevan, and Dr. E. Symes Thompson. Orator: Dr. F. W. Headland.

PRODUCTION OF SOFT SULPHUR.---M. Montier has shown that sulphur heated with 1-4000th of its weight of iodine becomes, by cooling, soft, plastic, and in great part insoluble in sulphide of carbon. He also shows that several organic substances, such as naphthaline, paraffine, creasote, camphor, and turpentine, modify sulphur in the same manner, when employed in about the same proportions. The temperature to which the sulphur must be heated, varies with the nature of the substances added: thus camphor effects a change at a temperature of 230° C., while naphthaline and turpentine require a much greater heat. The author was led to believe that it was the carbon in these substances which was influential, and he therefore made experiments with that body. He found that one part of carbon with 1000 parts of sulphur, at a temperature 270° C., effected the same modification.—*Journ. de Pharm.*

PREPARATION OF CURARINE (M. Preyer).---To prepare this alkaloid, treats the crude poison scraped off arrows, or obtained from the Indians in little clay pots, with boiling alcohol, and distils the alcohol from the solution. The residue is treated with water, and filtered to separate the resin, and the filtrate is precipitated by bichloride of mercury. The precipitate contains all the curarine. It is washed, suspended in water, and decomposed by sulphuretted hydrogen; and thus hydrochlorate of curarine is obtained in solution. The purification may be effected as usual. The soluble salts are all crystallizable. Curarine has a bitter taste, is soluble in water and alcohol in all proportions, insoluble in ether, benzole, and sulphate of carbon. Pure concentrated sulphuric acid gives to curarine a magnificent and lasting blue colour, which serves to distinguish it from strychnine.—*Buchner's*.

INTRODUCTION OF PEROXIDE OF HYDROGEN.---Dr. Richardson lays the following claim to the introduction of peroxide of hydrogen as a therapeutic agent. The peroxide of hydrogen, made at his instance for medicinal purposes, and now so largely manufactured by Mr. Robbins of Oxford-street, is prepared on and by the original process of the illustrious discoverer of the peroxide of hydrogen, the French chemist, Thénard. The credit, if there be any, that is due to him in respect to the use of this substance as a medicine, rests on the circumstances: 1. That he was the first experimentalist who investigated the physiological properties of the peroxide of hydrogen. 2. That he drank the first doses of it to test what could be borne by the human subject. 3. That he determined what volumetrical strength of the solution could be practically employed in medicine. 4. That, as a remedy for disease, he introduced it originally into practice.

SPURIOUS CARBOLIC ACID.---Mr. W. Crookes writes: "The Cattle Plague Commission have recommended carbolic acid as a disinfectant. A spurious article composed of oil of tar, utterly valueless as a disinfectant, is now being imposed on the public. The iniquity of this fraud claims exposure. Commercial carbolic acid is soluble in from 25 to 70 parts of water, or in twice its bulk of a solution of caustic soda, while oil of tar is nearly insoluble. To apply these tests: 1. Put a teaspoonful of the carbolic acid into a bottle; pour on it half a pint of warm water; shake the bottle at intervals for half an hour; when the amount of oily residue will show the impurity. 2. Dissolve one part of caustic soda in ten parts of warm water, and shake it up with five parts of the carbolic acid. As before, the residue will indicate the amount of impurity."

POISONING BY CASTOR SEEDS.---On Saturday evening, March 17th, Mr. Joshua Allen, residing at 9, Bath-street, Poplar, was seized with violent vomiting and purging, accompanied with burning pain in the gullet and stomach, and all the symptoms of Asiatic cholera. Dr. G. C. Kernot,

surgeon, of Chrisp-street, Poplar, was immediately sent for, and found him suffering from an irritating poison. Upon inquiries, he found he had been persuaded by a man in the docks to eat a few castor oil seeds, which at once revealed the cause of the illness. The unfortunate man lies in a very lamentable condition: his recovery is extremely doubtful. It is not commonly known that the seeds from which castor oil is extracted contain in the embryo a very active poison, and that a few of them are sufficient to produce violent purging and death.

AN ARTERIAL IRREGULARITY.---At a meeting of the Vienna Medical Society, Professor Patruban exhibited a preparation showing an infracostal artery. The vessel arose as a common trunk from the subclavian, ran a short course to the upper border of the first rib, and there divided into the external mammary artery, which followed its ordinary course, and an infracostal artery of large size. The latter vessel ran obliquely over the inner wall of the anterior part of the thorax, anastomosed with the other intercostal arteries, and passed outwards at the sixth rib to be distributed to the muscles of the chest. Dr. Patruban observed that this abnormal artery was of importance in regard to medicine, surgery, and forensic questions. For instance, in empyema, in paracentesis thoracis, in necrosis of the ribs, in fractures, &c., fatal hæmorrhage might take place from this artery.—*Wiener Med. Wochenschr.*

THE CATTLE TRADE.---The absolute suspension of the cattle traffic on the Great Eastern Railway renders it interesting to recapitulate the receipts of that undertaking from the conveyance of cattle, sheep, and pigs during the last seven half-years. In the six months ending March 31, 1862, this branch of business produced the company £24,260; in the six months ending June 30, 1863, £50,744; in the six months ending December 31, 1863, £25,391; in the six months ending June 30, 1864, £54,988; in the six months ending December 31, 1864, £54,988; in the six months ending June 30, 1865, £49,737; and in the six months ending December 31, 1865, £22,298. It will be seen that the first half of the year is the most lucrative as regards the movement of cattle; and as in the current half-year the company is not likely to have the benefit of more than two months' cattle traffic (while even during that period it was greatly reduced), the diminution of the receipts under this head cannot fail to be serious, although the increased carriage of dead meat will be to some extent a compensation. On the other hand more cattle than formerly are now being forwarded from Norfolk to the metropolis by sea.

THE AMERICAN ARMY.---During 1861 and 1862 the mortality in the army from disease was more than five times as great as that of men of the same age in civil life, being 48.7 men per 1000 in 1861, and 65.2 per 1000 in 1862. The total number of deaths from disease alone during the two years was 56,193. The number of men constantly sick was about 10 per cent. of the strength of the army, and the total number of cases treated, including wounds, was 878,918 during 1861, and 1,711,803 during 1862. The most fatal disease was camp fever, of which 19,459 died during the two years. Of diarrhœa and dysentery 11,560 died, and from inflammation of the respiratory organs there were 8090 deaths. The army was remarkably exempt from scurvy and from the diseases that result from intemperance and vice. When the hospital system was at its *maximum* there were in the country 202 general hospitals with 136,894 beds. There were over 1,000,000 patients treated at these hospitals, and of the whole number treated but 8 per cent. died.

ACCUMULATION OF STABLE MANURE IN LONDON.---Dr. Septimus Gibbon, in his fortnightly Report presented to the Board of Works, Holborn District, on March 12, 1866, draws attention to the non-removal of stable manure from the mews, laystalls, and streets of London in consequence of a clause of the Cattle Disease Prevention Act 1866, which forbids the exportation of manure, offal hides, &c., from the Metropolis or any other place in which cattle plague has existed within six months previously. This provision extends from March 1 to April 15. The Board have memorialised the Home Secretary on the subject, which has come under the notice of the House of Commons and the Government. We may add that orders for removal are easily obtained through the police, except in cases where there is reasonable fear of infection by Rinderpest.

Notices to Correspondents.

Students.—According to the most recent views as to the atomic constitution of bodies, the equivalent number of mercury is again fixed at 200. The matter would be an unimportant one (except to theoretical chemists) except that the nomenclature of calomel and corrosive sublimate is affected by these changes of opinion, and serious mistakes might arise in practice by any confusion being allowed to exist in naming or prescribing these important drugs.

A First Year's Man.—If you attend regularly the lectures of the Professors and read up the subjects for yourself, you will not have much time to devote to hospital practice at present, but you ought, nevertheless, to visit the wards as often as opportunity is afforded.

J. H.—Four years is the minimum period now required for medical study, and the candidate must pass the examination in Arts before he commences attendance at the Hospital.

Amicus.—Enough has already been said and written on the subject, and it may now be allowed to drop.

A Young Surgeon.—The appointment can only be obtained by making interest among the Directors of the Company. The salary is about £120 a year, with some perquisites.

Dr. B.—We cannot say that we approve the practice, but *de gustibus non disputandum*.

Mr. Griffin's letter is inserted.

The Royal Institution.—The notice has been received.

The Obstetrical Society of London.—The report arrived too late.

A. J.—As far as we are aware, the appearances in the arteries in gangrene from ergot, are identical with those of dry gangrene from other causes, except the ossification of the coats, which not uncommonly precedes the latter form. The main artery and we believe its branches are blocked up by coagula, and the lining membrane reddened. Brown-Séquard has shown that the internal administration of ergot produces contraction of the capillaries, and hence the value of the (aqueous) extract in hemorrhages. If we be not mistaken, Thompson, in his treatise "On Inflammation," speaks of the condition of the vessels from ergot in the chapter on mortification.

MEDICAL APPOINTMENTS.

ENGLISH.

CLAYWORTH, C. C., L.R.C.P., Edin., has been appointed House-Surgeon to the London Hospital.

HARRISON, MR. ROSSALD, has been appointed Junior Surgeon to the Liverpool Northern Hospital.

MCCORMACK, M. J., M.B., has been appointed Medical Officer of Health for the Borough of Southampton.

ROBERTS, F. T., M.B., B. Sc. Lond., has been appointed Physician to the Liverpool Northern Hospital.

IRISH.

BEAMISH, M., M.D., has been elected Vice-President of the County and City of Cork Medical Protective Association.

LYONS, R. D., M.B., F.K.Q.C.P.I., has been appointed to the Richmond Hospital, Dublin.

Births, Deaths, and Marriages.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

CHRISTIE.—On April 1, at Pembroke House, Hackney, the wife of T. B. Christie, M.D., of a daughter.

NEILSON.—On April 2, at Blairgowrie, N.B., the wife of James Neilson, of a son.

NOWELL.—On March 19, at Cornwall Villas, Westbourne-park, the wife of A. H. Nowell, L.R.C.P., Edin., of a son.

SEALY.—On March 20, at Oakland's-park, Weybridge, the wife of G. J. ealy, M.D., of a daughter.

HUBBARD.—On March 27, at 22, Ladbrooke-gardens, Notting-hill, the wife of W. Hubbard, L.R.C.P., of a daughter.

LATHAM-O'HARA.—On March 21, at Ballymoney, T. Latham, M.B., to Anne, daughter of C. O'Hara, Esq.

WILKINSON-LEADBATER.—On March 22, at the Cathedral, Manchester, T. J. Wilkinson, L.R.C.S. Edin., to Miss Jane Leadbater.

WISE-SHARP.—On March 23, at St. Margaret's, Plumstead, A. Wise, M.R.C.S., to Marie Jane, eldest daughter of John Sharp, Esq.

STEWART-YOUNG.—On March 20, at Lanarkshire, Izett Stewart, of Welhall, to Marion Waterstone, youngest daughter of A. K. Young, M.D., of Bayswater.

BECKETT, A. R., L.F.F.P. and S. Glasg., at Liverpool, on March 10, aged 28.

BROWNE, ROBERT CAVE, M.D., at Barnet, on March 22, aged 66.

CAMBRIDGE, DR. S., at Cheltenham, on March 19, aged 94.

DAVIES, SAMUEL S., M.R.C.S., L.S.A., at Pembridge, Herefordshire, on February 12.

HAWKINS, JAMES, L.R.C.P., Edin., at Newport, Monmouthshire, on March 21, aged 52.

MACKENZIE, W., M.D., late of E.I.C.S., at 14, Carlton-terrace, Edinburgh, aged 86.

MAY, W., M.D., at Madeira, on March 21, aged 56.

THOMSON, E. D., Army Medical Department at Gibraltar, on March 6, aged 32.

ADVANCED PAYMENTS.

SUBSCRIBERS are reminded that their subscriptions in all cases must be paid within two months of the date of the order to secure the advantage of the lower rate of £1 1s. 8d. per annum, and that any subscription delayed beyond that period will be charged on the credit scale of £1 2s. 6d. per annum.

Original Communications, Hospital Reports, Society Proceedings, and other matter of considerable length, should reach our Office not later than FRIDAY EVENING for insertion in the following Wednesday's issue. No exception to this rule can be made. Important information—Telegraphic News, and other matter occupying only a short space—can be received up to Monday evening. Authors' corrected proofs must in all cases be returned to the Office not later than 10 o'clock on MONDAY MORNING, and no alterations can be attempted to after that date.

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29.909 in. The mean daily reading was above 30 in. on three days of the week. The barometrical pressure was 29.10 in. on Sunday, and it was 30.05 in. on Monday and Friday.

The general direction of the wind was W., N.W., and S.W. * The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the 10 years 1851-60 to the present time.

Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

* The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in workhouses situated outside the municipal boundaries.

† The mean temperature at Greenwich during same week was 40.2 deg.

ROYAL COLLEGE OF SURGEONS, IRELAND.

Thomas Beaumont, M.D., Indian Army, was admitted a Fellow of the College on the 23rd February last. In THE MEDICAL PRESS of the 7th March, by mistake, this gentleman's name was published as having been admitted a Member.

WEEKLY METEOROLOGICAL REPORT FOR THE WEEK ENDING APRIL 7th, 1866.

Prepared especially for THE MEDICAL PRESS and CIRCULAR by J. H. STEWARD, Optician, 406, Strand, and 54, Cornhill, London.

April, 1866.	Barometer reading reduced to 32 degrees.	Thermometer.		Dry bulb.	Wet bulb.	Wind.		Remarks.	
		Max.	Min.			Direction.	Force.		
1st	29.050	54	48	47.05	42.05	S.W.	—	000	Very dull.
2nd	29.040	50	38	43.05	41.05	N.W.	—	002	Showery.
3rd	29.060	50	39.05	45	41	N.N.E.	—	000	Fine.

PRIZE MEDAL — INTERNATIONAL EXHIBITION, 1862.

**A SUPERIOR FORM OF LIEBIG'S FOOD,
FOR INFANTS AND INVALIDS,**

Contains the same ingredients, and in the same proportions, as recommended by BARON LIEBIG; but, owing to the mode of preparation, the troublesome and tedious operations of

BOILING & STRAINING ARE AVOIDED,—LANCET, July 29 & Oct. 14.

The great success of this Food is a convincing proof that it perfectly fulfils its object.

REPORT BY DR. HASSALL.

"I have subjected the Food prepared by Messrs. Savory & Moore to full examination and analysis, in both its uncooked and cooked conditions; and I find it to be eminently adapted for the Food of Infants and Invalids, being highly nourishing, and, what is of the greatest consequence, of easy digestibility.

"ARTHUR HILL HASSALL, M.D.Lond.,

Author of 'Food and its Adulteration;' Senior Physician to the Royal Free Hospital."

Sold in Tins, 1s., 2s., 5s., & 10s. each.

BARCLAY AND SONS; CROSSE AND BLACKWELL; EDWARDS AND CO.

**NEW PREPARATIONS FOR OPHTHALMIC USE, INTRODUCED BY
MR. ERNEST HART.**

DISCS OF GELATINE IMPREGNATED WITH—

ATROPINE, CALABAR BEAN EXTRACT, IODIDE of POTASSIUM, MORPHIA, ERGOTINE, BROMIDE of POTASSIUM, BROMIDE of AMMONIUM.

See THE LANCET, Jan. 16th, 1864: Mr. ERNEST HART's Paper on the Use of Gelatine as an Ophthalmic Medium. Also, *ibid.*, April 16th; On the Atropized and Calabarized Gelatine. — "These transparent discs dissolve admirably in contact with the moistened conjunctiva. Nothing can be imagined more practical."—ANNALES D'OCCULISTIQUE, June 30th, 1864.

THE PANCREATIC EMULSION: a New Remedial Agent.

Originated by **Dr. DOBELL**, Physician to the Royal Infirmary for Diseases of the Chest.

Vide THE LANCET, Nov. 11th and 18th.

This Preparation is now made on an extensive scale, and the Price is therefore considerably Reduced.

N.B.—The TRUE PANCREATIC EMULSION has an acid reaction, and is readily miscible with water or milk.

Preparations in IMITATION of it have an alkaline reaction, and are not miscible with water or milk.

SAVORY & MOORE,

NEW BOND STREET;

1, Lancaster Gate, Hyde Park; 29, Chapel Street, Belgrave Square.

NEWBERY'S NEW GLUTEN CAPSULES.

COPAIBA, COPAIBA AND CUBEBS, AND COPAIBA AND CITRATE OF IRON.

GLUTEN *versus* GELATINE. — GLUTEN AS AN ENVELOPE IMMEASURABLY SUPERIOR.

Beautifully made; egg shape.
Regular in size.
Contain no air-bubbles.

More convenient to take.
Smaller than those of other makers.
Though containing usual quantity.

Pleasanter in action.
Do not cause eructations.
If tried, will be approved.

Bottles of 36 Capsules, 2s. A liberal allowance to the Profession.

FRANCIS NEWBERY & SONS (Established A.D. 1746), 45, St. Paul's Churchyard, London, E.C.

No. II.

ECZEMA.

By T. W. BELCHER, M.A., M.D. Dub.,

FELLOW, CENSOR, AND EXAMINER, KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND; PHYSICIAN TO THE DUBLIN DISPENSARY FOR SKIN DISEASES; AND EDITOR OF "NELIGAN ON DISEASES OF THE SKIN," 2ND EDITION. 1866.

(Continued from page 332.)

E. C., a female child, aged three years and a half, residing at Irishtown, was brought to me at the Dispensary for Skin Diseases on the 24th of March, 1864, with a cutaneous eruption of several months' standing on the scalp. Her general health had not been very good, and she presented a very cachectic appearance. The eruption I may shortly describe under the term *eczema capitis*. It was preceded by heat, tingling, and itching; no clear information could be had as to the appearance of distinct vesicles; serous exudation had continued for a considerable time; scabs appeared in some places, and from a few of them pus had exuded; cracks or fissures were discernible in other parts; and still further might be noticed what, to an ordinary observer, seemed scales. These caused the patient much itching. At the time of her first visit the hair was partly falling off.

I directed the hair to be cut close, and kept so by repeated use of the scissors; to keep the scalp clean, and to apply with a brush the strong tincture of iodine, which I generally use for such purposes. It is made with methylated spirit instead of with proof spirit; and in this I think it has a great advantage over the official preparation in any affections for which the local use of tarry preparations, or of medicines allied thereto, may be thought desirable.

The application was repeated several times, and during this period she occasionally took alterative powders of mercury with chalk.

On the 4th of April (1864), she showed symptoms of what is often called "a bad state of the system," by the breaking out of small boils on the scalp.

Cod-liver oil, in drachm doses, thrice daily, was given from this date; and on the 16th of May she was discharged cured of the skin disease, and very much improved in her general health.

I shall now give an illustration of a different form of *eczema*.

J. H., aged 19, by occupation a porter, was admitted to the Dispensary on the 18th of April, 1865, with a (nearly) circular *eczematous* eruption on both arms and legs, and on the scrotum. I arrived at the conclusion that it was a case of *eczema impetiginodes* for the following reasons:—

From some of the patches arose a serous, from others a sero-purulent exudation; but on nearly all there was to be seen a constant formation of yellowish-brown scabs.

The quantity of the discharge was very great in this case; I have never seen it greater in any other, and it was a source of much inconvenience as well as annoyance to the patient, who had all the while to follow his daily labour. The tincture of iodine was applied here after the manner detailed in the last case; it was frequently repeated, and throughout the patient took the solution of the arseniate of soda (Pearson's solution) in three-minim doses, thrice daily. At first he took it in infusion of quassia; after a

while this was changed to infusion of gentian; and finally, the vehicle used was infusion of cascarrilla. The patient steadily improved, and all traces of the disease having for a short time disappeared, he was discharged, apparently cured, on the 21st of July, taking the arsenical mixture up to that day. His treatment lasted about three months. He was very well ever since until the middle of last month (March, 1866), when he again came to the Dispensary with a very slight return of his former malady. I may return to his case in a future paper.

Eczema in a more ordinary and more closely typical form occurs frequently on the scalp of infants during teething. On reference to my private case-book, I find that just about the same time (April, 1865), I was attending a gentleman's child, aged about five months, who was affected in this way. The tincture of iodine was tried in this case also, and when it had stopped the copious "weeping," I resorted to ointments to allay the intolerable itching which the little patient felt. I tried first of all Prof. Macnamara's "*Ceratum lauro-cerasi*" (see his edition of "*Neligan's Medicines*," p. 292). This soon lost its effect, and then I tried with more success a cerate of cold cream with chloroform, twenty minims to the ounce. Finally, I completely succeeded with thirty minims of it to the ounce. The cerate was kept in a stopped phial, and throughout the child had alterative, and occasionally purgative, medicines.

I think we may deduce some practical lessons from the consideration of *eczema* as brought under our notice by these cases.

The first is this: that the *eczema* of books and the *eczema* of practice are not always identical.

In my experience the purely typical disease is not so often met with as the complicated. I here take the term complication in its widest sense, as not only comprising the complication of *eczema* with other distinct cutaneous diseases, but also, and chiefly, the complication of the typical form with one or more of its known varieties.

In the first of the cases just detailed there was not *prima facie* any complication; but had we seen it earlier, we probably should have noticed the typical form which passed away with the acute inflammatory stage, on one part of the scalp, and the disease as it appeared on the 24th of March, 1864, on other parts.

In the second case it was clearly complicated in the sense above given. On reference to several cases recorded by me in the *Dublin Quarterly Journal* during the past year, I find in the February number (page 252) a case of scabies with *eczema*, and a case of *eczema impetiginodes*. Again, in the May number (page 495), another instance of the same kind, and also one of syphilitic *eczema*, which, however, we shall not now discuss, as it should be properly ranked among the "syphilides." Further, in the August number (page 254), a very remarkable case, to which I have particularly referred in my edition of "*Neligan on the Skin*" (page 105). Here the patient had, at the same time—1, on the right arm, a typical *eczematous* eruption (*vesicular*); 2, on the left arm an *impetiginous* eruption; 3, on the left cheek an *erythematous* blush. In a fortnight after, the diseased skin of the left arm became "rimous"—the *eczema fendillé* of Hardy and the French school.

I may further observe, in connexion with this subject, that greasy applications are not favourites of mine in *eczematous* cases. I find that they rarely do good. The local treatment which I mostly adopt is such as I have already described; where itching is troublesome, stuping with infusion or decoction of bran is of great service, and mucilage of starch, applied night and morning, in almost every case "mops up" the weeping, and fits the case for the local application of iodine. In inveterate cases where the skin is in the scaly stage, and where there is no infiltration, I repeatedly have used Hebra's tincture, or *tinctura saponis viridis cum pice*, with good effect, and I can confidently recommend it. Its composition and mode of application I quote from my edition of *Neligan*, p. 114:—"This con-

sists of equal parts of tar, soft soap, and methylated spirit. It should be applied twice daily, suffered to dry on the skin, and washed off with soft soap or petroleum soap; the only kinds, I may add, which ought to be used in this disease. This preparation, as its name denotes, was invented by Professor Hebra of Vienna, and was recommended to me by Dr. McCall Anderson of Glasgow, about two years ago.

But it is on the constitutional treatment that I place most reliance in cases of eczema. Iodide of potassium is good, but arsenic is much better; and I never met a case yet that stayed with me long enough and was not cured.

It will take months—from three to nine, I find—to effect a cure, but it can be done, and only by combined perseverance on the part of both patient and physician. Most of the cases I have met with have been with Dr. This and Dr. That; but, with scarcely an exception, none of the many doctors has had fair play from the patients. The patient generally gets dissatisfied when not cured at once, especially when the disease gets aggravated, as it almost always does immediately preceding the amelioration caused by continuous arsenical treatment.

Another capital error is not to continue the constitutional treatment for some months after apparent cure. This is instanced in the second case given in this paper. The patient reappears in eight months with the disease in a mild form. It should be remembered that medicines and local applications which suit one case will often prove useless in another, which to all appearance may be similar. I heard a story lately of an archdeacon who dabbled in physic at his country living. He invested in Neligan's work, and commenced to treat the skin diseases of his parishioners. He tried one remedy advised by Dr. Neligan; success did not attend his efforts, and he pronounced Neligan "no good."

Perhaps few conditions retard the cure of eczema in old persons so much as mental depression. This condition I have found to exist when the lengthened use of one medicine seems to them quite useless. "Nothing is being done for me," says the patient. Well, in such case I would say continue the arsenic, or other remedy as the case may be, changing the vehicle frequently. This will be found to have been illustrated in the second case above given, where the patient took arsenic in three different infusions. I now think it answers well enough to give it in water, with some colouring matter in it to prevent mistake.

Except to dermatologists, the question, what is the essential lesson in eczema, is it a vesicle or not? is of minor importance; seeing that whether eczema be held to include many diseases or few, in point of fact the treatment of most of these diseases, or varieties, resolves itself into one principle, and may be practically the same. I will not here enter into the nature and cause of eczema and the law of elementary lesions, nor shall I pit Hebra and the Germans against Willan, and Hardy and the French against the English school. I have entered more fully into this part of the subject in my edition of Neligan, which I have occasionally quoted. For the foreign and more fashionable theory I may refer to Hebra's views, as fully explained by his pupil and friend, Dr. McCall Anderson of Glasgow, in his monograph on eczema; and also to a review on skin diseases in the *British and Foreign Medico-Chirurgical Review* for this month. For the other side—the views of the school of Willan—see an exhaustive essay in the January number of the same review, by that learned physician, Dr. Tilbury Fox.

THE Paris *Moniteur* of Sunday contains a list of 300 medals—namely eighteen in gold, 178 in silver, and 112 in bronze—granted at the suggestion of the Minister of Agriculture by his Majesty to those of the medical profession who proved during the late visitation of cholera their zeal and devotedness in the care of the sick. The *Moniteur* points out 122 instances of private heroism on this occasion, which proves that, notwithstanding the silence observed by the official papers during the visitation, it was of a sufficiently serious nature to justify the public alarm.

CASE OF SPECTRAL ILLUSIONS.

By BENJAMIN BELL, F.R.C.S.E.

(Read before the Royal Medico-Chirurgical Society, Edinburgh, April 4.)

THE following case seems to possess considerable value in a scientific point of view, from the rare circumstance that the subject of it exhibits no impairment of her mental faculties, knows her false perceptions to be illusory, and is able to describe them in a very intelligent and graphic manner. She is a lady, considerably beyond eighty, of healthy constitution and vigorous mind, still takes a lively interest in passing events, and is surrounded by a circle of friends and acquaintances who cultivate her society for the attractive nature of her manners and conversation. It is proper to mention, that for more than a year, she has been debarred from both reading and writing, employments in which she previously took great pleasure, by the partial formation of cataract in both eyes. Although vision is thus considerably impaired, she is by no means in darkness, but is able to recognize large objects, and, to a certain extent, the persons of her intimate friends. In other respects she enjoys good health, without being exempted from occasional catarrhal affections and temporary disturbances of the digestive function.

In the month of July, 1865, she began to be annoyed by noises which she likened to the ringing of bells of various sizes; some of them small and clear, other so loud and deep in their tone as to resemble church bells in close proximity to the back of her bed. About the same period she observed on the curtains and on the walls of the room a variety of beautiful landscapes, in some of which were figures of men, women, and children, which occasionally seemed to be in motion. These landscapes underwent frequent changes in the manner of what are called dissolving views. Sometimes, in place of them, every surface—the bedclothes, the curtains, the walls—are covered with tasteful patterns, as of embroidery or carving in wood. Not unfrequently the air of the apartment was occupied with what seemed to be a dense fall of snow. These false visual perceptions were little influenced by the amount of light or by closing the eyelids, although they were more distinct at certain periods of the day than at others. The noises, however, were invariably loudest and most distracting during the night.

As a general rule, the pulse was unaffected. There were no indications of cerebral congestion; no flushing, no headache, no giddiness. Her most comfortable time was for an hour or two after retiring for the night, when she usually partook of a moderate allowance of gin and warm water. She was in the custom of falling asleep almost immediately, and of awaking free from both the ringing of bells and the phantasms. Both of these sources of annoyance, however, were sure to return after a short interval, and the remainder of the night was spent very uncomfortably.

Various things were tried without obvious benefit—iron, opium, henbane, aconite. The stomach being in some degree out of order, probably from continued sleeplessness and mental distraction, powders were prescribed, containing rhubarb, potash, and calumba. Under the use of these, in sufficient doses to regulate the bowels, considerable improvement took place, the noises becoming greatly moderated and the phantasms much less vivid.

About the end of September the temporary improvement ceased, and the phenomena underwent a remarkable modification. Instead of landscapes and carved work, she now saw innumerable female heads and busts covering every surface on which she turned her eyes—the bed, the curtains, the walls of the room, the carpet, and even the persons of her attendants. All the countenances were pleasant to look upon, some of them very beautiful; no two faces were alike, and none, at this time, bore any resemblance to people she had ever seen before. The costume and mode of arranging the hair were quite different from what we meet with in the present day. The faces

were varied every morning, sometimes more frequently and the style of dress underwent corresponding changes. The spaces left betwixt the full-sized forms were filled by others on a smaller scale. If, as sometimes happened, one of the larger faces was seen in the space previously occupied by a real picture suspended on the wall of the room, it was always observed to be accurately in the centre of the frame. All these heads had the appearance of exquisitely finished pictures, and were exclusively female, the majority of them young and beautiful.

On the 11th of October the faces were, for the first time, *male*, with large, strongly-marked features and dark eyes, which glared upon her and seemed occasionally to move. On the 12th they were still masculine, but milder in expression, and a certain number seen in profile. Next day the portraits suddenly disappeared, and were succeeded once more by representations of beautiful carved work in oak and mahogany, such as baskets filled with flowers and other things of an analogous nature; these being replaced, in their turn, by tabular inscriptions, apparently in a foreign language, which she was quite unable to decipher. Another day came, and all these things were superseded by an array of female heads, with a few men interspersed, among whom she recognized the well-known features of Dr. Thomas Chalmers and a profile of Professor Miller.

Subsequently to this, for several weeks, the human faces gave place to an inexhaustible succession of wood carvings, apparently, as before in oak and mahogany, of flowers, geometrical figures, and patterns of female ornaments.

Early in December the faces returned in great numbers, and were much more distracting and oppressive, from the circumstance that, instead of resembling portraits as formerly, they were now entirely life-like, both in size and colour. Moreover, the eyes were now seen to move, and were full of meaning. The great majority were youthful and good-looking, with the hair tastefully combed back from the forehead, and in some instances powdered. On the curtain, at the foot of her bed, she could count ten rows of these countenances, with eight individuals in each row. Occasionally she recognized her deceased husband in the crowd; but this, like the other instances already mentioned, was an exception to the general experience, that the countenances had never been seen before.

Towards the close of the year the faces became, if possible, still more distracting to my patient. They were intensely life-like, the eyes moving, and even the mouths opening and shutting in a very disagreeable manner. Sometimes a small picture or fac-simile of the individual would emerge from the eye or mouth, and then gradually enlarge until it took the place of the original. The faces answering to this description were very numerous—men, women, children. They were no longer arrayed in the costume of a former generation, but in the garb of the present day; and many of both sexes were eminently handsome. It was noticed at this time, as on one or two previous occasions, that the illusions became greatly moderated, contemporaneously with the accession of a certain degree of febrile disturbance.

During January, 1866, a good many variations took place in the phenomena, the figures being one day numerous, large, and disagreeable, on another day, small, bright, and beautiful, gracefully arranged upon a straw-coloured surface, like a vision of fairyland. As formerly noticed, they invariably disappeared at once when she had swallowed her allowance of gin and water on retiring to rest. The same effect was produced on one or two occasions during the day, when, in consequence of the illusions being more oppressive and distracting than ordinary, she had recourse, after some persuasion, to the same remedy. At this period the effect of an opiate was again fairly tried, but little benefit was experienced, and it seemed to derange the system.

Since the beginning of February there has been a gradual but very decided amelioration. During a few days, in place of human figures, she saw in one corner of the

apartment, a group of beautiful grey horses, as large as life, and, at the foot of her bed, a crowd of tortoise-shell kittens, with their eyes intently directed towards her. These living objects were succeeded once more by patterns of embroidery and wood-carving, and, several times lately, on awaking from sleep, about midnight, she has observed five male heads peering at her over the foot-board of the bed, while she seldom fails to see in one corner, a pleasant looking young matron quietly engaged with her work. Generally speaking, her condition is much more comfortable than it was for many months; the noises are now quite bareable; she takes her food with considerable relish, and has recovered her wonted cheerfulness which the long continued distraction had well-nigh taken away.

The chief point of interest in the foregoing history, is the perfect conviction on the part of the lady herself that the perceptions of which she was conscious had no external or tangible origin. As they were confirmed neither by her own sense of touch, nor by the senses of her friends, her sound judgment pronounced them to be illusory; had she been incapable of thus exercising her reasoning faculty, she must have fallen into the error of other persons, similarly affected, and have believed the perceptions to be real. In strict language, they *are* real; as real as the normal perceptions of sight and hearing, of which we are all conscious. But there is this distinction, these abnormal perceptions are *subjective* in their cause, depending upon a condition of the sensorium induced *ab intra*; whereas, normal perceptions are *objective*, and caused by impressions made, *ab extra*, on the nervous structures of the eye and ear. The physical causes of these subjective perceptions are necessarily very obscure. That they are independent of organic change of structure is more than probable, from the very noticeable fact, that the psychical phenomena undergo so many variations, and sometimes cease entirely. May we suggest, that whatever lesions of a permanent nature may sometimes be discovered after death, either in the substance or in the membranes of the brain, these illusory perceptions are occasioned by more or less disturbance of the capillary circulation in certain structures intimately connected with sight and hearing—namely the *corpora quadrigemina* and the *auditory ganglion*?

Mr. Craig of Rathis, has published a remarkable case,* in which spectral illusions, resembling in many points those which I have described, continued to recur during the long period of twelve years, and were ultimately superseded by serious and fatal lesions of the brain.

Some years ago, I attended a lady, upwards of sixty, who had been for a long time afflicted with an abiding noise in the head, so loud and distracting that she compared it to the clashing together of metallic vessels. It continued for several years, uninfluenced by treatment. One day, I found her rejoicing in a sudden and complete cessation of the morbid sounds; before the lapse of many hours, she had an apoplectic seizure with *hemiplegia*. She recovered her senses and lived a paralytic for some years; but the noises never returned. A post-mortem examination could not be obtained.

These instances confirm the very obvious conclusion, that perceptions, depending on subjective causes, whatever the exact nature of these may be, are sources of anxiety, particularly in persons well advanced in years, with whom the vascular system is prone to fatty degeneration and other morbid changes.

It appears to me, that the medical treatment ought to be regulated by a due regard to all the circumstances of the case, and not by any preconceived theory.

In the case related in these pages, there has never appeared to be any call for depletion; and, indeed, the opposite plan of procedure has generally afforded at least temporary benefit. On the other hand, it was found in Mr. Craig's case, that any addition to the small quantity

* Edin. Med. and Surgical Journal, No. 129. To Mr. Craig's account are appended some valuable pathological observations by Dr. David Craigie, which will amply repay a careful perusal,

of wine, to which the patient restricted himself, always increased the number and vivacity of the images.

Let me add, in conclusion, that a case, such as the foregoing, in which abnormal perceptions are accompanied by an unclouded state of the mind, capable of recognizing their true nature, may give us insight into recorded instances of spectral illusions in which the mind itself was in all probability disordered. Need we wonder also at the psychical phenomena exhibited in fever, in phrenitis, in delirium tremens, where, in addition to the parts of the *encephalon* specially associated with sight and hearing, we have reason to believe that the whole cerebral mass is more or less affected, either by inflammatory action or by a poisoned condition of the blood, when we know that it is possible for such an infinite variety of landscapes and figures, animate and inanimate, to be spread before the mental eye of one whose reasoning faculty pronounces them to be illusions? Let us suppose that ruling faculty to be in complete or partial abeyance, with similar phantasms crowding in endless variety upon the sufferer, and we shall have, as it appears to me, a ready explanation of much that is absurd, impulsive and violent in the behaviour of many who are in that unhappy predicament.

A REMARKABLE CASE OF TRANSFUSION OF BLOOD, ATTENDED WITH COMPLETE SUCCESS.

Noted by AUSTIN S. MELDON,

LICENTIATE OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS, AND
OF THE ROYAL COLLEGE OF SURGEONS, IRELAND;
LICENTIATE IN MIDWIFERY, ETC. ETC.

THE following remarkable and interesting case of transfusion of blood from one human being to another occurred in Berlin a few days since:—

Early on Monday morning, the 12th inst., a young man, residing in the Neuen Friedrichstrasse, was found apparently lifeless on the floor of his apartment.

Dr. Badt was immediately in attendance, and declared it to be a case of poisoning by carbonic acid gas (Kohlenoxydgas). He had the body at once removed to a spacious room having free access of air. Artificial respiration was had recourse to, and every effort made, both by Dr. Badt and Dr. Sachs to resuscitate the man. At first there seemed but little hope; but perseverance soon brought its reward, and the physicians had the satisfaction of perceiving a return of the natural respiration, accompanied by a feeble pulse. The patient gradually improved, and there now seemed every prospect of recovery. Towards two o'clock, however, the pulse became almost imperceptible; the respiration became slow and short, and in fact, all the symptoms of approaching death began to develop themselves.

As the last resource Dr. Badt proposed the operation of transfusion. Professor Geheimerath Martin consented to operate, and at three o'clock, assisted by his son, as well as by Drs. Badt and Sachs, he introduced a previously well-warmed tube into the median vein and slowly injected blood. The result was extraordinary: the pulse increased in strength, the respiration became deeper, the eyes immediately opened; the cheeks, before of a ghastly pale, reddened, and in a few minutes he was able to swallow a little water.

Nevertheless, he lay in an almost unconscious state until midnight, and seemed to be on the very brink between life and death. On Tuesday morning, however, he was so far recovered as to be pronounced out of danger.

The blood in this case was taken from his brother, as well as from a commissionaire.

I may observe that cases of poisoning by carbonic acid gas are of frequent occurrence in almost every part of Prussia, owing to carelessness in shutting the valve of the stove, by which the gas, generated by the burning wood or coal, is unable to escape.

I am given to understand that Dr. Martin has practised this operation with the greatest success in cases of flooding.

Wilhelms, Strasse, 58, Berlin.

RETROSPECT OF THE MEDICAL JOURNALS.

APRIL 14.

THE *Lancet* alludes to the investigations about to be held into the state of the London workhouse infirmaries by Dr. Smith and Mr. Farnall, under the direction of the Poor-law authorities. It is gratifying to find the value of the report of the Commission is thus officially recognized.

Drs. Farre and Lankester seem to differ on the subject of the prevalence of infanticide in the English metropolis. The former has read a paper before the Statistical Society on the high rate of infantile mortality in these realms.

It seems likely that the surgeons will emulate the example set by their obstetric brethren, and that we may soon expect an exhibition of surgical instruments.

Our contemporary regards with satisfaction the reappointment of Dr. Sharpey to the Medical Council.

Dr. Tuke writes to the *Lancet*, and very properly complains of the unjust and hypercritical remarks made by Dr. Forbes Winslow in reviewing the evidence given by the former before the Capital Punishment Commission.

The cattle plague returns show a very marked decrease in the number of cases.

Mr. T. Carr Jackson describes a case of large fibro-areolar tumour of the thigh in a young man who was exhibited to the Pathological Society. The growth resembles that often met with in the scrotum.

Dr. Dodgson gives a case of cerebral disease in which the power of speech was lost, and where the lesion was found to be in the neighbourhood of that spot where that faculty was localized by M. Broca—viz., the third convolution on the left anterior cerebral lobe.

A number of cases are alluded to in the Middlesex Hospital in which Mr. De Morgan's plan of painting the surface of all wounds with a forty-grain solution of chloride of zinc was adopted, apparently with the best effects.

From the *Medical Times and Gazette* we learn that Dr. Richardson is at present engaged in a series of experiments with regard to the combination of styptics and caustics with the ether spray in the instrument now so largely used by the profession.

Dr. Salisbury's observations on the influence of low organisms in producing intermittent and remittent fevers are certainly novel, and if corroborated will mark out a new era in medicine. He has found these cryptogamic productions in the expectoration of ague patients:—

1. Cryptogamic spores are carried aloft above the surface at night, in the *damp exhalations* which appear after sunset; they fall again after the sun rises.

2. These bodies rise from thirty-six to sixty feet, never above the summit of the damp night mists or exhalations, and intermittent fever observes the same limits in its occurrence.

3. The day air of ague districts is free from the 'bodies' in question."

Dr. Bowerbank gives his experience of cholera as gathered during its outbreak in Jamaica, the letter is highly interesting and well worth perusal; although he does not describe it as a cure, he tells us that in the seventeen cases in which sea water was used by the patients internally, not a death occurred, the fact is worth remembering. He gives us some startling instances of persons buried alive.

From the *British Medical Journal* we learn that the bravery of Mr. Llewellyn, the Surgeon of the *Alabama* who perished in the discharge of his duties to the wounded, has excited the most wholesome feelings of admiration in India. Dr. Partridge of the Bengal army writes to the governors of Charing-cross Hospital, enclosing £336 13s. 5d. the amount subscribed to the Llewellyn fund, with a request that it may be allocated by the Hospital authorities in such a way that Dr. Herbert Llewellyn's name may be perpetuated. We are glad to see a prospect of the testimonial fever showing symptoms of a more healthy and practical aspect than formerly evidenced by commemorative but useless statues and medals.

Hospital Reports.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

TREATMENT OF DELIRIUM TREMENS BY CAPSICUM.

(Under the care of Dr. LYONS.)

THE following case is a well-marked instance of the efficacy of this somewhat unusual plan of treatment:—

The patient, a man aged 40, by occupation a warehouseman in a wine-merchant's establishment, was admitted into the Whitworth Hospital on 25th March. He presented the usual symptoms of delirium tremens, wandering, illusions, tremor, attempts to get out of bed, loss of sleep, sweating, a certain amount of pyrexial disturbance, and required a special attendant to control and keep him in bed, and ultimately the strait waistcoat had to be employed.

The statements of his wife, and subsequently of himself, as to his previous habits were most unsatisfactory and not a little contradictory. About four years previously he had suffered a severe shock, under circumstances connected with loss of the greater part of his pecuniary resources. It was alleged that he was not an habitual drinker, nor at any time a drinker to excess; statements little in keeping with his symptoms and appearance on admission.

Five days previous to admission he was seized early in the morning with shivering, sense of choking, and violent pain in the head. On the following day mental wandering and illusions began to display themselves, accompanied subsequently with flushing of the face, occasional wild raving, and violent delirium.

When seen on the 25th, he presented the well marked phenomena of delirium tremens, and for many days and nights had had no sleep.

Dr. Lyons having, on more than one occasion, previously employed with success the treatment by capsicum, specially recommended to his notice by his friend, Dr. Kinnear, Director of the Melville Royal Naval Hospital, Portsmouth, determined to give it a further trial in this case, in which, for various reasons, it appeared to be indicated, and ordered the patient thirty grains of the powder of capsicum, to be made into a bolus and administered immediately. The dose was taken without any difficulty, notwithstanding that some slight burning sensations were felt in the mouth and throat for a time, and a sense of diffused warmth through the stomach and bowels for a brief period subsequently. In less than one hour after the bolus was taken he fell into a quiet sleep, and some three or four hours subsequently awoke, perfectly calm, conscious, and convalescent. It is much to be regretted that notwithstanding that he was perfectly reasonable, and in all respects quite free from any symptoms whatever of the condition of delirium tremens, a draught containing 30 minims of gutta nigra was administered about 10 a.m., this medicine having been ordered in the morning, to provide for the possible failure of the capsicum dose; but of the efficacy and satisfactory result of the former no reasonable doubt can remain. No stimulants were employed at any time in this case. Convalescence was rapidly established, and the man left hospital in a day or two, himself and his wife in no little degree surprised at the almost magical effect produced by the dose of so familiar an article as that employed.

The results obtained by Dr. Lyons in the use of this drug fully bear out the experience acquired on a far larger scale of observation in the West Indies and in the Melville Hospital by Dr. Kinnear, Dr. Lawson, and others of his distinguished colleagues in the public service at home and abroad. In the records of the Melville Hospital not less than from seventy to eighty cases are reported to have been

successfully treated by the sole use of this drug in single or repeated doses, ranging from one scruple upwards. No gastric disturbance or other unpleasant symptom has been at any time noticed.

As a stimulant of great and immediate efficacy, Dr. Lyons considers that its action may be explained by the direct influence it exerts upon the gastric expansions of the vagi, and so indirectly upon the cerebro-spinal centres. The phenomena of the disease he considers to point to a double condition of stimulated excitation and partial paralysis of distinct and perhaps opposite portions of the nervous system.

For general employment it cannot be doubted that, as pointed out by Dr. Lyons, the use of capsicum offers many advantages over either opium or digitalis. In cases of recurrent delirium tremens associated, as they often are, at a somewhat advanced period of life, with fatty degeneration of the heart, both the latter drugs are very distinctly contraindicated, and their use has not infrequently been attended with results far from satisfactory, even when free from fatal result, which has not always been the case.

MEATH HOSPITAL.

CASES UNDER THE CARE OF MR. PORTER.

Reported by ARTHUR WYNNE FOOT, M.D.

DURING the past month the advantages of local anaesthesia, according to Dr. Richardson's method, have been very fully tested in many operations by Mr. Porter, senior surgeon to the hospital. The following are a selection from his cases:—

Case 1.—Sarah Malahan, aged 18, admitted with the left upper extremity rendered almost useless from an extensive webbed cicatrix, the result of a burn, occupying the flexure of the elbow, and binding the forearm to the arm. The ether spray was applied to the cicatricial tissue previous to its division, which was made without the girl feeling any pain.

Case 2.—Jane Hanlon, aged 19, was admitted, anxious for the removal of an unsightly blackened scar, about half an inch in length, on the middle of her forehead, caused by a blow from a piece of coal received about two years since. The ether spray having been applied, the cicatrix was excised without her feeling any pain.

Case 3.—John Keough, aged 60, affected with an abscess in the scalp, the result of erysipelas. The ether spray having been applied, the abscess was opened without any complaint of pain.

Case 4.—Mary Scanlon, aged 40. The displaced flap of a wound in the palm of the right hand required removal, which was done without pain after the application of the ether spray.

Case 5.—Christopher Curtis, aged 45, admitted with a fatty tumour of twelve years' growth, about the size of a turkey egg, on the back of the neck. The ether spray having been applied, the tumour was excised without any pain during the first incision.

Case 6.—John Tobin, aged 11; an abscess in the left eyelid, opened without pain, after the application of ether.

Case 7.—John Doyle, aged 60, admitted with an anthrax, about two and a half inches in diameter, situated above the right shoulder, midway between the back and front of the neck. The ether spray was applied with two instruments, and the surface having been frozen, a crucial incision was made without any complaint of pain on the part of the patient.

The majority of the cases selected by Mr. Porter for the trial of the local anaesthesia have been peculiarly suited for its successful employment, being those in which the operations involved but comparatively superficial structures. No application was made to the skin preliminary to the distribution of the spray, the rapid action of the ether preventing the occurrence of the painful sensations which sometimes precede the congelation when the action is

prolonged. In such Cases as 3 and 6, an additional advantage is derived from this method, the contraction of the tissues under the influence of cold assists in the evacuation of pus and the obliteration of the cavity of an abscess. In none of Mr. Porter's cases did there appear to be any delay to an early union, neither was reaction painful. The most extreme degree of congelation is not necessarily unfavourable to rapid union. In a discussion upon local *anæsthesia* in the Imperial Society of Surgery of Paris, on March 14, M. Broca mentioned a case where Robert removed the great toe so congealed that during the operation the assistants could hear the flakes of ice crackling under the bistoury. There was no pain, no blood was lost, and the flap healed by the first intention. The employment of two instruments, necessary in Case 7, from the extent of the surface to be rendered insensible, has been obviated by the construction by Dr. Richardson of a multiple instrument combining three distinct jets, movable to various angles, worked with a single pair of small bellows which can act effectively upon a surface of the body three inches long by two wide. The ether employed by Mr. Porter was pure, free from methylated compounds which cause irritation of the skin, left no persistent odour on evaporation, and boiled briskly in the warm hand.

ST. VINCENT'S HOSPITAL.

CASE OF BRIGHT'S DISEASE.

(Under the care of Dr. MAPOTHER.)

THE following case is given with a view to bear out the usefulness of the treatment ordinarily adopted by Dr. Mapother in cases of Bright's disease. The history and the symptoms of it correspond to a large extent to those of another case reported in THE MEDICAL PRESS AND CIRCULAR for the 4th April:—

J. K., *ætat.* 52, a married man, by trade a slater, and a resident of Dublin, was admitted to St. Vincent's Hospital on 3rd April, 1866. About three years ago he was an inmate of the same hospital, and was then affected with œdema of both legs.

On the present occasion he was somewhat similarly affected, but the swelling is now greater than it was three years since.

He traces this œdema to exposure to wet and cold when engaged in his trade about a fortnight before the 30th of March. At the latter date the swelling began, and gradually increased up to the time of his admission to hospital. He did not complain of anything else, save some cough and difficulty of breathing. He passes urine in natural quantity.

As in the former case, just referred to, he was directed to take a tartrate of potash mixture, also one drachm of compound powder of jalap every night.

I saw him for the first time on the 4th of April, when Dr. Mapother tested his urine for albumen, and by the ordinary nitric acid test it was found in considerable quantity.

On the 12th instant I had another opportunity of seeing him in company with his medical adviser. He was then very much better; the œdema had completely disappeared, and so indeed had most of the symptoms for which he obtained admission to hospital. His urine was tested this day, and its *sp. gr.* was ascertained to be 1014. It was also tested for albumen—none whatever could be found; but the urine contained much colouring matter.

The practical point in this case, as in the former one, is the speedy amelioration which ensues from or after treatment like that here noted.

THE Emperor of the French, at the suggestion of the Minister of Agriculture, has granted 300 medals—10 in gold, 178 in silver, and 112 in bronze—to those of the medical profession who, during the late visitation of cholera, evinced zeal and devotedness in the care of the sick.

Proceedings of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MARCH 27TH.

Dr. ALDERSON, F.R.S., President.

A CASE OF LUMBAR COLOMOTOMY (AMUSSAT'S OPERATION), SUCCESSFULLY PERFORMED FOR THE RELIEF OF A VESICO-INTESTINAL FISTULA.

By T. HOLMES, M.A. Cantab.,

SURGEON TO THE HOSPITAL FOR SICK CHILDREN, AND ASSISTANT-SURGEON TO ST. GEORGE'S HOSPITAL.

ULCERATED openings sometimes take place between the bladder and either the small or large intestine, which have no connexion with previous stricture of the gut, still less with cancer. In those cases in which the fæces come from the lower bowel, and are consequently more solid, great suffering is produced, and the formation of calculus in the bladder becomes exceedingly probable. In such of these cases as are not dependent upon malignant disease, colotomy, by diverting the fæces from the fistulous channel, may possibly enable the latter to close, and is at any rate necessary in order to relieve the sufferings caused by the fæces passing into the bladder. The author read the notes of a case in which communication existed between the bladder and some part of the bowel above the rectum, and in which Amussat's operation was performed eight months since; the patient being now in good health, and in a condition of tolerable comfort, with evidence of considerable contraction, if not complete closure, of the fistula. References were also made to some other cases of communication between the bowel and bladder, with a view to support the opinions here put forward and the treatment adopted in the above case; and also with a view to the diagnosis of the seat of the communication with the bowel when out of reach of the ordinary means of examination.

Mr. SOLLY thought the Society was indebted to Mr. Holmes for his case. The profession was not fully alive to the value of Amussat's operation in cancerous diseases of the rectum, and the case related would improve our knowledge of the operation in other than malignant diseases. One peculiarity of interest in it was, that the operation was performed when the colon was not distended, which rendered the proceeding a difficult one. In his (Mr. Solly's) cases the intestine was full, and the operation very simple and easy. He would inquire whether the cavity of the abdomen was opened before the colon was reached?

Mr. HOLMES COOTE said that very few surgeons had had personal experience of Amussat's operation. He had not operated upon the living, but had on the dead subject. The proceeding when the colon was distended was simple and easy; not so when, as in Mr. Holmes's case, the intestine was in a state of collapse. The case was interesting from the complete relief afforded to the patient, and from the fact that the disease was of a non-malignant character. Did the ulceration arise from tuberculous deposit, which might be only of temporary existence, and a complete cure follow?

Mr. CURLING said that the remark made by Mr. Holmes Coote, a surgeon to a large hospital, that he had not yet had occasion to perform colotomy, seemed to confirm the observation of Mr. Solly, that the operation was not sufficiently appreciated by the profession as a means of giving relief in many cases of painful disease. In the interesting case which had just been read, no doubt could exist as to the propriety of opening the lumbar colon, and as to the great advantage which might result from such a proceeding. We had only to contrast the great misery, ending in death, which existed in the case communicated by Mr. Morgan to the last volume of the Society's "Transactions"—in which the ileum opened into the bladder, surgery being powerless in affording relief, with the comparative comfort and release from all suffering now enjoyed by Mr. Holmes's patient—to conclude that, in this instance, the operation

was a triumph of surgery. In his (Mr. Curling's) opinion the principal interest of the case consisted in the diagnosis which had been so carefully and successfully made—in determining, chiefly from the solid character of the fæces which passed from the bladder, and from the free escape of urine by the rectum, that the opening from the bowel was in the larger bowel low down. He would endeavour to follow the author of the paper in confining his observations relating to colotomy to cases of non-malignant disease without obstruction. He believed that there were many cases of the kind to which this operation was applicable—cases of inveterate stricture of the rectum, with ulcerations and mucous growths, attended with an exhausting discharge, the patients going from hospital to hospital for relief, leading a miserable life, and ultimately dying of the disease. Mr. Pennell, whose interesting case of colotomy had been alluded to by Mr. Holmes, in his paper communicated to the Society sixteen years ago, remarked that he would have recourse to this operation in every case of incurable stricture of the rectum, which produced severe suffering, and was beginning to destroy the health and undermine the constitution. He (Mr. Curling) was not aware that this suggestion had ever been acted on, until six weeks ago, when he was induced to perform the operation in the London Hospital on a man only twenty-seven years of age, who had an obstinate stricture and a diseased state of rectum such as he had described. The man was not pressed to submit to the operation, but when the circumstances of the after-condition were fully explained to him he begged to have it done. He recovered favourably, and under tannic acid and chloride of zinc injections the discharge from the rectum was greatly reduced; but it was too early to speak of the effect of diverting the channel for the fæces, and of other treatment, in bringing the rectum into a more healthy state. Colotomy was supposed to be a dangerous as well as a difficult operation. When performed in consequence of obstruction arising perhaps from cancerous disease, and delayed to the latest period, being resorted to only as a *dernier resort* after a stoppage of three or four weeks, the operation was necessarily fatal in many instances. Owing perhaps to accidental circumstances, it had fallen to his lot to perform an unusual number of these operations. His experience extended to fourteen cases; eleven he had performed himself, and he had assisted in three other cases. Now, in nine the operation was undertaken to relieve obstruction, in all from carcinomatous disease; five were fatal, and four recovered; but in none of the fatal cases could death be said to result from the direct effects of the operation. In the remaining five cases, in which there was no obstruction, the operation was performed to relieve the distressing symptoms of disease in the rectum. All of them recovered favourably. So that with this experience we are justified in saying that colotomy is not attended with any great danger. He had not met with any serious difficulty in opening the colon in the cases where no obstruction existed. He attached great importance to securing the bowel to the margins of the wound in the skin, so as to bring the gut near the surface, and to prevent feculent matter escaping into the sigmoid flexure below, as this was liable to be a source of trouble. He trusted that the satisfactory result of the author's case, and the discussion which had taken place that evening, would tend to remove much of the prejudice which existed against colotomy, being assured that it was capable of diminishing suffering and prolonging life in many cases of serious disease.

Mr. HOLTHOUSE could confirm the observations of Mr. Curling as to the great depth of the bowel from the surface in many of these cases, as well as to the necessity of securing the edges of the intestinal opening close to the cutaneous one. He (Mr. Holthouse) had had some experience in the performance of Amussat's operation, and nothing was more striking than the difference of depth at which the colon was situated in different cases. When this intestine was distended above the seat of the opera-

tion, it pressed towards the surface, producing such a stretching and apparent thinning of the superimposed structures that a trocar might be thrust at once into the bowel without any fear of wounding the peritoneum. In other cases, on the contrary, the colon was empty and contracted, sometimes not larger than the finger, and lay at a great distance from the surface. This was the condition of the patient in the last case operated upon by him, and which indeed somewhat resembled that of Mr. Holmes, inasmuch as a communication had formed between the intestine and the bladder. With the view of acquiring a correct knowledge of the relative anatomy of the parts concerned in this operation, and the appearances which indicate the proximity of the colon, Mr. Holthouse, some years ago, made a number of dissections of the region implicated. The parts were dissected both from before and from behind, and the following was the mode of proceeding:—The abdomen being opened and the small intestines removed, a long carpet-pin was thrust directly backwards through the descending colon, one inch above the crest of the ilium, till it emerged through the skin in the loin. Taking the average of the cases examined, the lower end of the kidney was found to be two-thirds of an inch above the transfixed part of the colon, and internal to it. The intestine itself lay on a layer of fat and the anterior lamella of the lumbar fascia, which separated it from the quadratus muscle. In performing Amussat's operation, therefore, after cutting through the skin and subcutaneous tissue, together with the superficial muscles, one arrived at a very strong dense fascia (fascia lumborum) connected with the internal oblique and transversalis muscles externally, passing beneath the outer margin of the erector spine and in front of the quadratus. On dividing this and the last-named muscle, a layer of fat or omentum-like structure, which varies in thickness, comes into view, and immediately behind this is the uncovered portion of the colon. Mr. Holthouse regretted, with previous speakers, that colotomy was not more frequently resorted to, and, when performed, that it was not done earlier. He had on several occasions recommended its performance, but it was either declined or put off till too late. The case of Mr. Gracie (Mr. Pennell's patient), which had been referred to by Mr. Holmes and Mr. Curling, was a striking example of what the operation could effect. Mr. Holthouse had had the advantage of seeing that gentleman when he was in London some years ago, and as evidence of the completeness of his recovery it might be mentioned that he was in the habit of walking from his lodgings in Piccadilly to the Docks and back again without experiencing any inconvenience. His chief anxiety was lest the artificial anus should close up.

Mr. CURLING rose again to state that he had under his care in the London Hospital, at the present time, two patients upon whom he had performed colotomy—one, to whose case he had already adverted, and another, a young man, aged 20, with cancerous disease of the rectum—without obstruction. And he should be happy to show the cases to any Fellows interested in the subject. He would also add, that he had once operated in a case of extreme lateral curvature of the spine, and had succeeded in reaching the bowel above the anterior-superior spinous process of the ilium without opening the peritoneum.

Dr. MARCET related a case of obstruction of the intestine, which was removed by injections of large quantities of olive oil.

Mr. HOLMES then replied. He said that the peritoneal cavity was not opened in the operation. The difficulty in reaching the colon depended upon its being in an abnormal position—quite different, indeed, from its ordinary situation; but he succeeded in reaching it in the mode described in the paper. Usually, as the colon was distended, there was no difficulty in finding it, and this without opening the peritoneum; though this cavity had in many instances been laid open in this operation, and often without the knowledge of the surgeon. He thought

with Mr. Cooté that the case was one of ulceration of tubercular deposit, a form of disease by no means rare. He agreed that many cases in which Amussat's operation might be performed, with the result of prolonging life and affording much comfort, went now from hospital to hospital, and were submitted to instrumental and other interference. Occasionally in these cases, after operation, the comfort of the patient was dreadfully interfered with from the difficulty of fitting an instrument to the opening, and from the constant escape of fæcal matter and its offensive odour. When the bowels acted at regular periods, and the pad could be well adjusted, the patient experienced much comfort.

HARVEIAN SOCIETY OF LONDON.

MARCH 15TH.

J. WALKER, Esq., V.P., in the Chair.

A PAPER was read by Dr. C. MEREDYTH,

ON THE DUALITY OF VENEREAL ULCERS.

The author observed that since the successive incorporations of the simple chancre, the chancrous bubo and blennorrhagia into the symptoms of syphilis by Viller, Nicolas Massa, and Brassavola. The disease has been described under two sections—blennorrhagia and syphilis.

The common property of all venereal diseases being that they were contagious and transmissible by intercourse, had caused them to be attributed to a common principle called the "venereal principle." Hence, it was naturally derived an unity of disease; but the anomalies and contradictions venereal affections constantly presented, have induced many eminent writers to seek for their elucidation, and the result of their investigations is, that it is owing to the artificial grouping under one head of three distinct diseases, essentially different. The issue to be decided is, therefore, the source of the manifestations of syphilis. The adherents of the old classification maintain, that all ulcers of the genital organs spring from one source, whilst the partisans of more recent research affirm, that the ulcers of the genital organs are due to two sources, one giving rise to a purely local affection, the other to a constitutional disease, creating a diathesis. The assertion that the doctrine of the plurality of venereal diseases is new is unfounded, as can be historically proved by reference to all the writers on affections of the genital organs from the most remote period up to the end of the fifteenth century, the epoch when the great epidemic broke out in Italy, during the invasion of Naples by Charles VIII. of France. All the contemporaries of that fearful calamity agree in saying that the disease was *new*, *unheard of*, and *unseen* before, refractory to all treatments that had hitherto been efficacious in combating affections of the genital organs. The celebrated and circumstantial description of the new disease by Fracastor, who lived long enough to observe its downward march, sets forth all the premonitory and successive symptoms of the primary, secondary, and tertiary evolutions of the disease, as they are observed at the present time. The confusion was effected by degrees and became consummated half a century later, when the contemporary observers of syphilis, as Fracastor had styled the new disease, had passed away. This confusion has held its ground for three centuries and a half, and it seems incomprehensible how such a cause of error should have remained undetected and unassailed for so long a time, especially as, although the characteristic induration of the new ulcer has come down to us in one unbroken claim from the time of the great epidemy to the fifteenth century, it cannot be traced back beyond that period. Mr. Rollet argues that, if it be not admitted that the simple chancre, the chancrous bubo and blennorrhagia have, at a given time, been wrongly confounded with syphilis, it must, at any rate, be admitted that it is syphilis itself, which has degenerated into the simple chancre, the chancrous bubo,

and blennorrhagia. That argument I adopt. The hypothesis that "the differences observed in the chancre are due to the peculiar idiosyncrasy of the person, state of his health, or constitution, susceptibility or non-susceptibility to the reception of the disease, condition of the tissues in which the virus has been deposited, and source from which it has been obtained cannot be maintained, except the source which is everything, as M. Basserian demonstrates beyond dispute, in the tenth section of the second chapter of his 'Traité des Affections de la Peau Symptomatiques de la Syphilis.' The conclusions deduced are, that the influence of temperament makes itself truly felt only in the form of the symptoms, their progress, their course, and their greater or less disposition to give way or resist treatment; further, that neither age, nor sex, nor idiosyncrasies, nor temperaments, nor constitutions, nor bad sanitary habits, nor seasons, nor intercurrent diseases can be considered as a determining cause of the generalization of syphilitic accidents in the system." The active analogy between the virus of syphilis and that of vaccine cannot hold good beyond the first stage. The two diseases inoculated in their first stage, both determine a diathesis, but beyond the first stage the two diatheses cannot be compared, inasmuch as the vaccinal diathesis is no longer inoculable when the vesicle is transformed into a pustule, whereas syphilis is inoculable in all its forms, even in the blood drawn from a syphilitic subject. Without admitting the reproduction of chancres invariably in their own form and consequences, it is impossible to account for the fact that that most inveterate syphilizer, Dr. Lindman, who inoculated on himself the prodigious number of 2200 chancres, never produced an indurated chancre previous to inoculating himself with matter taken from ulcers on the tonsils of one of his friends in full syphilitic evolution. The same thing happened to Dr. Warnery of Lauzaune. The theories of M. Langhbert and Professor Boeck to account for the various aspects and consequences of chancres rest on pure hypothesis, unsupported by facts, experiments, and observation. The doctrines of the dualistic school do not rest on theories and hypotheses; they are based on well-defined principles deduced from the teachings of M. Ricord, and generally admitted—viz., the whole chancre is to be found in the pus it secretes; the chancre of inoculation is always the analogue of the chancre that produced it. In other words, the identity of the effects is due to the identity of the cause, which is to be found in the symptoms themselves. The soft chancre and the infecting chancre once clearly established to be two independent nosological species, there is nothing contrary to the laws of pathology to find their coexistence in one or more spots in the same subject. The ulceration participating at the same time of both species of chancres is the character of the chancre mixte. This coincidence can happen but in three ways—first, by the contagious principles entering simultaneously at one point; second, by the infections being supposed on the local; third, by the local on the infections. These three modes of double contagion are illustrated by three observations of experiments due, the first to M. Bulchion Robert, the second to M. Lindwurn, and the third to M. Laroyenne in the "Annaire de la Syphilis, 1859." Much misapprehension results from the term chancre mixte, due to the necessity of nomenclature. It is a misnomer. The chancre mixte is not a nosological species; the term is meant to express the coexistence or coincidence of two distinct nosological species of ulcers of different contagious diseases on the same person. The doctrines of the dualistic school are here but pointed to, there is neither time nor space to enter into detail. Originality of ideas is not sought for, but the author merely desired to direct attention to a subject well worthy of elucidation by patient investigation.

To Mr. LANE.—I have made more than 1500 inoculations, always with a negative result.

Mr. GASCOYNE.—If he denies the coexistence of the two chancres in the chancre mixte, he must deny the vaccino-

syphilitic chancre. Baumes and Spérino have mixed the pus of the simple chancre with vaccinal matter, and have obtained first a chancre, and then vaccine.

Mr. DE MERIC.—The cause is that the affection had been described in a mess, hence the confusion.

Mr. JAMES LANE said that having been connected with the Lock Hospital for some sixteen years, he had had many occasions to study the doctrines referred to by the author of the paper, and he held the same opinion now as he did twenty years ago—*i.e.*, that there was a unity of syphilitic ulcers. He thought it was not much to the point what Fracastor said or those who lived long ago. The true date of the theory of dualism was fifteen years ago, when Dr. Bassereau wrote his work on the subject. How many facts he had seen were in direct opposition to the theory of a duality of syphilitic poison; syphilisation, for example, was every day showing the identity of the poisons. Some weeks ago he had wanted some fresh matter to syphilise a patient, and he took some pus from two sores on two individuals. The first one was a soft chancre, the second a typical hard chancre. He inoculated the matter from the front on one thigh, and of the other on the other thigh on the same patient. The results were precisely similar as to incubation appearance of the ulcer, &c. This has been done before by others. Again, one of the leading doctrines of the dualistic school is that the hard sore is not inoculable on any person who is affected with constitutional symptoms of syphilis. Now this we have had done over and over again. In order to make the hard sore inoculable, it is only necessary to irritate it and it becomes inoculable again. At the same time he must observe that it had been often asserted that the soft sore was very easily inoculable; this was not by any means always true, since there was frequently great difficulty in getting inoculation to take, even from soft sores.

Mr. GASCOYNE avowed himself a partisan of the school of the ancients. The source of the ulcer had a great deal to do with the form it assumed. From a hard chancre it was difficult to get any result from inoculation, and if matter was taken from a soft sore existing on a syphilitic patient, it was often followed by infection of the person who was inoculated by it. To get over such difficulties as these, the *chancre mixte* had been created. Dr. Mostyn had spoken of cases where a man had had what was called soft sores, which were afterwards followed by secondary symptoms. Some time ago a soldier, at the Lock Hospital, had had soft chancre of the penis. The matter trickling down, had inoculated the thigh, and a hard chancre appeared there.

Mr. COULSON was an adherent to the dualistic school. Neither Mr. Lane nor Mr. Gascoyne had explained away the arguments used by writers of that school, although it was easy enough to give difficult and critical cases. He admitted that inoculations had succeeded in persons who were being syphilised, but how was it in a virgin subject? Inoculations from hard chancres had always produced hard chancres in such persons. Syphilisation had certainly shown that some hard chancres might be inoculated from, when irritated by savine ointment, &c., but in other cases he had tried this could not be done, and he believed that Dr. Bidekap had failed entirely, when in Paris, to get any positive result from hard chancres. Now with soft chancres there was scarcely any trouble. He thought, too, with the author of the paper, that the history of syphilis pointed to the introduction of a hard sore at the end of the fifteenth century.

Dr. C. DRYSDALE observed that certainly the partisans of the duality of venereal ulcers had a great deal to urge on their side. As a general rule, there could be not the least doubt that persons who contracted constitutional syphilis had been infected by persons who had either had a hard sore or had suffered from eruptions. In a number of cases of wives infected by their husbands, he had found this to be the case. Still it was impossible to prove that soft sores did not give rise to secondary symptoms, since it contradicted the experience of so many excellent observers.

Again, syphilisation seemed to settle the question, since it had been proved over and over again by Boeck, &c., that matter either from indurated sores or from soft sores, when inoculated on persons with constitutional syphilis, sooner or later failed to produce any effect. The matter from indurated sores took a shorter time until the system was impregnated than that from soft sores. Probably the truth was, that the poison was the same, but in the case of the soft sore the inflammation ran so high as to block up the capillaries and prevent the infection of the system; whilst, in the case of the hard sore, the poison entered like vaccine lymph, without causing any disturbance for some time, and thus infected the whole circulation.

Mr. VICTOR DE MERIC hardly knew to what camp he belonged. If we listened to the dualists, the poison of syphilis had only existed 300 years; during a part of this time M. Ricord had worked, and it was curious that that gentleman should not have remarked what Bassereau had asserted to be so constantly the case. He distrusted these elaborately-framed systems. Thus the dualistic theory was very enticing, if we left out of our minds the possibility of incubation. He thought that, at the present age of the question, it was impossible to arrive at a positive result. There might be something in the age of the person, &c., who was infected that influenced the result. Everything did not lie in the phenomena we had witnessed. Ricord himself mentioned the body of the individual infected as one part of the causation of the sore. We must think also that there might be an increased resistance in some persons. The creation of the mixed sore had caused much confusion. He did not feel inclined to pay much attention to the hybrid sore; in short, both theories satisfied the mind, that there were weak points in both theories, which required the devotion of future inquirers to clear up.

Dr. BROADBENT was very strongly inclined to dualism. He believed that when inoculation had been made from hard chancres, it was really soft chancres that had been inoculated. As to the natural history of chancre, there was no analogy between it and vaccination. In America scabs were used for vaccination. If a scab would produce a perfect vesicle, the analogy failed.

Mr. R. N. DUNN asked Dr. Meredyth if he had not met with cases where secondary symptoms had followed a soft sore. Mr. Dunn had met with cases of this kind in his practice. He had a patient at present, a gentleman, he was treating for constitutional syphilis, who had been told by a Mr. Morgan, that as his was a case of soft chancre he would not have secondary symptoms, but six weeks after the primary one had healed a second sore appeared, with ulcerated sore throat.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Dr. MOIR in the Chair.

THE seventh meeting of the forty-fifth session of this Society was held in their Hall, 117, George-street, on the 4th of April, 1866, at eight p.m.

Dr. GRAINGER STEWART exhibited the following specimens:—

1st. An hydatid cyst of the liver, of the size of a walnut, which contained a quantity of cheesy-looking matter with fatty granules and numerous echinococcus heads. It was derived from the body of a woman who had died of syphilitic affections. It was evidently undergoing a retrograde metamorphosis, and it appeared to have led to no symptom during life.

2nd. From the same liver a small vascular nævus was shown.

3rd. A series of specimens illustrating the changes undergone by syphilitic masses in the liver. The first stage were masses of fibrous tissue of a slightly translucent appearance. The second were masses of a more cheesy non-transparent character. The third was characterised by an almost cretaceous appearance, with wasting of the tissues in the neighbourhood, and the formation of cic-

trices. This form of syphilitic mass was quite different (Dr. Stewart remarked) from the waxy syphilitic masses which he had previously described to the Society. The specimens were derived from a man who had died from syphilitic disease, under Dr. Stewart's care, in the Royal Infirmary.

4th. A specimen of cirrhosis of the liver, associated with syphilitic masses.

5th. A peculiar stricture of the duodenum, which had resulted from cicatrization of an ulcer. The patient had been under Dr. Sanders' care. He was a tailor, 51 years of age; had from boyhood been subject to vomiting; had various dyspeptic symptoms, increasing in severity some years before his death. In October, 1865, he had become so weak that he was obliged for the most part to keep his bed. He was admitted into the hospital in January of the present year. He had loss of appetite and complained of pyrosis and uneasiness, but not pain after eating. He vomited generally about one hour afterwards. He died exhausted. On post-mortem examination the only lesions found were in the duodenum and upper part of jejunum. Here there was a series of strictures dependent upon cicatrization of ulcers. Several other simple ulcers were found in that neighbourhood. The narrowest stricture was about the size of a crow-quill.

6th. A peculiar form of cancer of the stomach and small intestine associated with miner's lung. The patient had also been under the care of Dr. Sanders; had been healthy until the end of December, 1865, when he became dyspeptic, had pyrosis and vomiting; his bowels became very loose, the evacuations were watery, tar-coloured, and offensive. He also had great dropsy, but no albuminuria. He died exhausted, after gangrene, which followed on incisions made to relieve the dropsy. The stomach was of natural size; at several points there was thickening of the submucous cellular tissue. In the duodenum and throughout a great part of the small intestine there were numerous similar thickenings, mostly at the margins of the valvular conniventes. Some of these had ulcerated, and at other points cicatrization with a considerable deposit of pigment had taken place. The glands were swollen and infiltrated, but neither in them nor in any of the thickenings were distinct cancer cells found. There were very numerous large nuclei. Dr. Stewart remarked that it was difficult to say positively what this lesion was. It certainly most closely resembled the cancerous affections, differing from them only in its tendency to cicatrization.

Dr. TUKE exhibited several interesting specimens of diseased brains; one a case of disease of the right frontal convolution and of the orbital lobule, unattended by aphasia, and two cases of atrophy of the cerebellum, unaccompanied by any symptoms whatever, and in particular not associated with any deficiency in the power of coordinating the muscular movements of the body.

Dr. PATRICK KERON WATSON exhibited Dr. Gordon's (of Belfast) splint for fractures in the lower third of the radius, stating that while it was by far the best and most efficient apparatus for treating such fractures, all its advantages could be obtained, and all the disadvantages of the ordinary method of treating such fractures might be avoided, by shortening the ordinary splints, so as to permit the upper splint, or that upon the extensor surface of the forearm, just to cover the wrist-joint, while the extremity of the under splint, or that upon the flexor surface of the forearm, was kept just short of the wrist-joint, the hand being allowed to hang down after the application of the bandages. When such fractures were thus treated all unnatural displacement of the bones was avoided, and after the reunion of the bones the motion of the wrist and fingers remained perfect and natural, requiring none of that tedious education so constantly requisite when the ordinary method is employed.

BENJAMIN BELL, Esq., F.R.C.S., thereafter read a "Case of Spectral Illusions," which appears in page 393. The PRESIDENT and Dr. ARGYLL ROBERTSON made a few remarks upon this paper, after which

Dr. STRETHILL WRIGHT gave an interesting and profusely illustrated lecture upon "Galvano-puncture in Aneurism," minutely describing the apparatus to be employed, the mode in which it acts, and the best means of attaining the desired end. After which he exhibited, by means of the oxy-hydrogen microscope, a highly magnified view of the decomposition of water, of the coagulation of albumen, and of the decomposition of a solution of iodide of potassium. The escape of the bubbles of hydrogen from the one pole and of the free iodine from the other pole of the battery, in the latter experiment forming a particularly beautiful tableau. The thanks of the Society were then conveyed to Dr. Wright by the President for his interesting lecture and beautiful experiments, after which the Society adjourned for private business.

ON THE RELATION EXISTING BETWEEN THE SENSE OF TEMPERATURE, THE SENSE OF TOUCH, AND THE SENSE OF PAIN.

By A. F. SPRING of Lutlich.

THE following interesting case of Dr. Spring is almost unique, and affords a strong confirmation of the opinions of those who think the sensations of temperature, pain, and pressure, are conveyed through separate channels, or are perceived by separate centres. The patient was a female, aged 60, who had long suffered from hypertrophy of the heart, dyspnoea, and persistent bronchitis. From exposure to cold she became paralyzed, though without loss of consciousness or deviation of the tongue when that organ was protruded. The entire right half of the body, including the head, became insensible to temperature and to pain, but there was no loss of motor power; the muscular power, in fact, as measured by the dynamometer, being somewhat increased on the affected side. She could feel the slightest touch on the anaesthetized (?) side, and, when the eyes were closed, she could discover and pick up a pin from the floor. On washing the hands she could distinctly perceive the shock and movement of the water flowing over them, but was quite unable to distinguish whether it was hot or cold. In winter she could only perceive the temperature with the left half of the body, and the same when standing near a fire. The normal temperature of the skin on the affected side was maintained in every part, or differed only to the extent of 1° or 2°. Neither the pricks of needles nor strong pinching was perceived in the slightest degree. She suffered from neuralgia in the temporal region at night. In consultation with M. Schwann, the author ascertained that there was no diminution in the acuteness of the patient's perception in regard to impressions of weight and of contact. The hand lying prone on a table, and weighted with 500 grammes, readily distinguished the addition or removal of two or three grammes, and when weights were concealed in a cloth, and the amount estimated alternately by the two arms, no difference was remarked. From experiments made in the method suggested by Weber for determining the delicacy of touch by applying the points of compasses, it appeared that there was a considerable diminution of acuteness on the left, or healthy side, but a still more marked diminution on the right side. On the eighth day after this consultation the sensibility to pain returned, under the form of a painful formication, and from this time every object appeared hot to the patient, so that she was unable to distinguish ice from water at a temperature of 122°. This state lasted two months, when death occurred from an attack of apoplexy.

In this case the sense of variation of temperature, instead of being associated with tactile sensations, followed the same course as the sensations of pain, disappearing and reappearing, though modified with the latter. The muscular sense was intact, and the sense of touch was only deteriorated in regard to its perception of distance. The cause of these abnormal conditions was evidently seated in the nervous centres.—*Presse Médicale and Brit. and For. Med.-Chir. Review.*

ON THE APPLICATION OF CAUSTICS IN PILLEGMONOUS ERYSIPELAS.

ALTHOUGH cauterisation has formerly been employed in cellulose-cutaneous erysipelas, the method adopted by M. Long, a surgeon-in-chief of the French navy, presents some novel features. Three cases out of several have been recorded in illustration of this mode of practice. The first case was that of a brewer, whose right arm was swollen, painful, of a dusky red, and covered with livid vesications, the redness and swelling extending from the fingers to the axilla. There was deep-seated fluctuation, with fever, dilatation of the pupils, and a soft and regular pulse. Beef-tea was given with a mixture containing acetate of ammonia. Vienna paste was applied over thirty spots about half an inch in diameter in four longitudinal rows, and the limb was wrapped in cotton. The next day, as the patient was worse, fifty other applications of the escharotic were made over the whole surface of the arm, and more beef-tea was given. After this the delirium and fever ceased, and suppuration was fully established, the appetite was quite restored, and solid food was allowed. But the skin was extensively detached, and flakes of mortified areolar tissue were removed behind the elbow. Gradually, however, the condition of the arm was improved, and finally the wounds healed, and motion of the limb was restored. The two other cases presented an analogous condition of the skin and subjacent tissue, and were treated in the same manner with success. M. Long's object in this treatment is to arrest the mischief, prevent detachment of the skin, and give exit to the pus. Sixty or eighty cauterisations over a limb in the earlier stage of the disease, produce powerful counter-irritation, and in most instances the general condition of the patient becomes improved in twenty-four hours, the swelling diminishes, and the suppuration becomes limited. This plan may be adopted in traumatic erysipelas of the head. It is said that only two out of sixty cases thus treated terminated fatally. The application of the Vienna paste leaves indelible scars, but this disadvantage is considered unimportant considering the formidable nature of the disease.—*Jour. de Méd. et Chir. and Brit. and For. Med.-Chir. Review.*

Reviews.

REGISTER OF THE KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND: with Historical Introduction and an Appendix containing a Roll of the Presidents and Fellows from 1654 to 1866; an Obituary of Honorary Fellows, Candidates, Licentiates, and Licentiates in Midwifery, from 1692 to 1866; and a Catalogue of Pictures, Busts, &c., corrected to January 1, 1866. Pp. 128. Hodges and Smith, Grafton-street, Dublin.

WHETHER we view this work merely as a faithful register of the annual advance of one of the most ancient and time-honoured Medical Corporations of our city, or as it fully merits to be looked upon as a trustworthy record of the early history and vicissitudes attendant upon the birth of medical institutions in this country, the well-written and elegantly got-up work before us will, we doubt not, meet with that amount of commendation it so well deserves. The "Historical Introduction" brings us so far back as 1626, when the letter of Charles I. was issued for the incorporation of a College of Physicians in Dublin, which, however, was not acted upon on account of the disturbed state of the times. Be it remembered that at this period there was only one corporate community legally qualified to grant medical licences, Trinity College, so that when the project did, in 1864, obtain the sanction of Government through the instrumentality of Dr. John Stearne, Senior Fellow of T.C.D., we find the "President and Fraternity of Physicians" merely an examining body for that institution till, "in 1667, King Charles II. granted the first Charter of Incorporation to the

President and Fellows of the College of Physicians in Dublin." This Charter, while it preserved the terms of contract between the Provost and Fellows of Trinity College, and the Fraternity of Physicians, gave the latter the general powers of the London College, and specially entrusted to them the entire control of the practice of physic in Dublin. No person without their licence could practise in Dublin or within seven miles thereof; and the expressed object of the Charter was, the extirpation of quackery and empiricism, which it described as then rampant. These powers did not prove sufficient, chiefly because of the small area within which the College could exercise authority:—

"At the request of the College this Charter was surrendered 14th December, 1692, and William and Mary granted a new Charter dated 15th December, 1692, under which, and under some subsequent alterations made by Acts of Parliament, the College is now governed."

This most interesting portion of the work then reviews in a logical and succinct manner the various legal enactments, &c., bearing on the rank, &c., of members of the College and of the profession in general, combined with much curious information, and concluding with an account of the history of, and present rules, &c., relative to the Fellows, Honorary Fellows, Candidates, Licentiates, Licentiates in Midwifery, College Halls, Library, Reading-room, Museum, Medical Society, School of Physic, Sir P. Dunn's Hospital, and Examinations, &c. Then follows an alphabetical list of the names, qualifications, &c., of the members constituting the College in 1866, which, for method in arrangement, and correctness in detail, cannot be surpassed. The "Appendix" contains the names of many of the illustrious of the profession, who, members of this College, by the light they then, "in their little day," threw around the profession of physic to the present moment, shed lustre over the darkling shadows of the page of "Obituary," which, should it do no more than by thus proclaiming, that the "great and good" of the past "have not lived in vain," will not have been written to no purpose; and when the learned Editor shall fulfil his "intention at some future time to enlarge this Appendix into a work consisting of short biographical notices of each Fellow, Honorary Fellow, Candidate, Licentiate, and Licentiate in Midwifery, little has been given here beyond a correct list of the names of the President's and Fellows, with the dates of election or appointment, and the obituary above noted," the profession may look forward to a rich treat. In the meantime, we shall only say, that the little work before us reflects credit on all concerned in its production, does honour to the venerable College, a faithful record of which it is, and we feel assured will be a valuable accession to the library of every lover of physic.

ON THE CURABILITY OF CERTAIN FORMS OF INSANITY, EPILEPSY, CATALEPSY, AND HYS-TERIA IN FEMALES. By BAKER BROWN, F.R.C.S. (Exam.), Senior Surgeon to the London Surgical Home, &c. Pp. 85. Svo. Hardwicke, Piccadilly.

MR. BAKER BROWN has long been known as one of the boldest operators in obstetric surgery. He has not only invented new operations, but has in many instances been the first to introduce foreign operations into England. Sufficient to point to his various perineal operations as new or as improvements on the works of others; vesico-vaginal fistula, of which he is really almost the sole persistent champion in England; ovariectomy, at which he has worked for over thirty years, and in which operation he has lately introduced—perhaps one of the greatest improvements in modern surgery—the division of the pedicle by actual canter. Mr. Brown is in this last point, not as he is often styled, an innovator, but a reviver. Conservative, inasmuch as he can see good in the work of his professional forefathers, he is sufficiently liberal to pursue boldly and contest successfully any

measures which he believes to be for the welfare of suffering humanity.

Mr. Brown has met with great opposition to his views, and in reference to the subject of which he treats in this book a great number of objections have been raised, which, however, have very little to recommend them save their virulence. Based on the investigations of such eminent men as Brown-Séquard, Handfield Jones, Brinton and Lister, there will be little cavil raised against the scientific truth of the theory on which Mr. Brown acts. The class of diseases on which he dwells are those depending on (or arising from) a loss of nerve tone, caused by continual abnormal irritation of a nerve centre. Whichever of the terms, "inhibitory influence" (Handfield Jones and Lister), "reflex relaxation" (Brinton), or "reflex paralysis" (Brown-Séquard), be used, the fact is ceded by all, that "the energetic operation of an afferent nerve" (Lister), or some impression acting injuriously on an afferent nerve (Handfield Jones); or again, "an actually existing irritation" (Brown-Séquard), exerts an injurious effect on its nerve centre, this state being, as Dr. Brown-Séquard thinks, increased or diminished according to the activity of the irritation, causing with its entire removal, or, more probably, as Dr. Handfield Jones affirms, persisting after the cessation of the cause which has morbidly affected it. This latter view appears to Mr. Brown the more generally correct one, because it can hardly be expected that a gradual disease will be suddenly removed, there having been no time for recovery of nerve power. Still following Dr. Jones's theory, we are shown how "a nervous centre may be more or less completely paralyzed without having undergone organic change in consequence of some enfeebling morbid influence," and quotes from Dr. Gull a most interesting instance of complete paraplegia induced by sexual excess, in which nothing abnormal could be detected in the cord, even by careful microscopy. This was paralysis from simple exhaustion. Coming gradually closer to his own subject, we are told how "excessive consumption of nerve force in one part weakens it also in others," of which the general exhaustion induced by excess of venery is an example, and this can only be explained by the intricate commissural connexion between the various centres. Long and frequent observation convinced our author that a large number of affections peculiar to females depended on loss of nerve power, and that this was produced by peripheral irritation, arising originally in some branches of the pudic nerve, more particularly the incident nerves supplying the clitoris, and sometimes the small branches which supply the vagina, perineum, and anus. Closer observation satisfied him that the greater or less severity of the functional affections observed depended on the amount and length of irritation, and the consequent amount of loss of nerve power.

And here we come to one of the principal objections raised against this view and the treatment proposed. This theory of peripheral irritation, as Mr. Brown delicately expresses it, means nothing more or less than that many female diseases are either caused or increased in severity by indulgence in solitary vice. "But," say his opponents, "are the evils sufficiently great to warrant us in stating so objectionable an opinion to the friends of a young lady or to the patient herself? Are we justified in directing our treatment so prominently to this habit? Can we not (although it is not said in so many words) temporize, and hope for a better state of things?" Let Mr. Brown answer these questions himself. Nor are functional disorders the only consequence, but in some cases severe organic lesions. The progress of the disease may be divided into eight distinct stages, No. 8 being arrived at, by gradations more or less distinct, directly from No. 1.

1. *Hysteria* (including dyspepsia and menstrual irregularities.)

2. *Spinal Irritation*, with reflex action on uterus, ovaries, &c., and giving rise to uterine displacements, amaurosis, hemiplegia, paraplegia, &c.

3. *Epileptoid Fits*, or Hysterical Epilepsy.

4. *Cataleptic Fits*.

5. *Epileptic Fits*.

6. *Idiotcy*.

7. *Mania*.

8. *Death*.

My statement that death is indeed the direct climax of the series might be proved by several cases which have occurred in my own practice, one only of which I shall relate. This is preceded by a similar one in the practice of Dr. James Russell of Birmingham.

Mr. Brown's treatment is the removal of the clitoris, which is shown to be the principal seat of irritation, and he prefers it to Dr. Brown-Séquard's method of applying actual cautery, or of simply dividing the nerve subcutaneously. This last method he has long abandoned as being no more certain in its effect than kindred operations on various branches of the fifth nerve for tic douloureux?

With reference to those who are too timid to perform the radical cure, but "recognize the source of evil by continual application of the strongest caustics," we are rather pertinently told, that "it wants little argument to prove that, so far from this practice being beneficial, it is likely, by causing increased irritation, to be positively injurious."

In his preface, Mr. Brown says that he does not for one moment wish it to be understood that he claims any originality in the surgical treatment herein described, but at page 9 talks of the objections with which he has been met, "from the very novelty of these views." Mr. Brown deserves the highest credit for having in these days of enlightened pathology applied science as a justification for reviewing a practice without doubt oftentimes most beneficial, and, indeed, indispensable if a cure is wished; but, as in many other things besides medicine, the practice was the same centuries since, although the principles on which the practice was founded were rather obscure. Thus we find Paulus Æginetus and Ætius Amidus describing the operation in the sixteenth century, and at the late interesting *conversazione* of the Obstetric Society was a drawing of the knife and other appliances necessary for the amputation of the clitoris, as performed by Dionis in 1738. In the Library of the Royal College of Surgeons are a number of works treating of this subject, foremost among which is a most elaborate essay in Latin, dated 1827, by one Nagrodzky, a German. The oldness of the operation is, in our eyes, a recommendation, and we repeat that Mr. Brown is to be praised for endeavouring to break down the barrier of false delicacy but too frequently raised by modern practitioners. This subject is one of such vast importance that we hope on a future occasion to enter into a detailed analysis of the cases treated in this volume.

CARIES AND FISTULOUS TRACTS.—Every surgeon knows how troublesome is the treatment of this affection of bone. Slitting open the tracts and gouging the bone is not always feasible or effectual, and injections must often be resorted to. Solutions of nitrate of silver of various strengths and tincture of iodine are often used, and with good results; but we are bound to notice a series of cases published in the *L'Union Médicale* by M. Notta, an hospital surgeon of Lisieux in France. The lotion used for injecting the tracts is called the liquor Villati, and belongs to the Veterinary Pharmacopœia. Its composition is as follows:—Solution of subacetate of lead, one ounce; crystallized sulphate of copper, crystallized sulphate of zinc, of each half an ounce; white vinegar, about seven ounces. The cases quoted are certainly striking, and about a dozen injections a month (which are, however, somewhat painful) sufficed, on an average, to bring on the healing of the fistulous openings. Professor Nélaton has fully sanctioned the practice, and among the cases cited there are several which were under his care.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 18, 1866.

WORKHOUSE INFIRMARIES.

THE battle against the present Workhouse Infirmaries is still raging as fiercely as ever in the general as well as the medical press, and no opportunity is lost in exposing every instance of mismanagement or neglect occurring in these institutions. It would seem as if the public were now opening its eyes for the first time to the condition of the sick in the wards of workhouses, and not only are the penny-a-liners driving an excellent trade by hunting up every case presenting the slightest "sensational" interest, but the Poor-law Board, with the aid of the indefatigable Mr. FARNALL, C.B., is instituting a series of investigations to ascertain the manner in which all the officers discharge their duty, and the result of these inquiries is duly served up to the British reader every morning with breakfast. It must be confessed that the attacks made upon the Workhouse Infirmary system are becoming too indiscriminate, and many stories are now credited, which are but indifferently authenticated, while trivial matters are sometimes brought into undue importance, and people who scarcely deserve the infliction are subjected to the lash of general censure.

This vehement onslaught upon the local authorities is, however, amply justified by their previous insolence and brutality, and even if some of the attacks made upon them may lie open to the charge of exaggeration, it must be remembered that for many years the most atrocious abuses have been allowed to prevail under the sanction of local authority, and all attempts to remove, or even expose them, have been frustrated by the parties inculpated, who have been moreover shielded by the Poor-law Board. This Board, founded for the express purpose of controlling the local authorities, has actually played into their hands by conniving at their misdeeds, and whenever any official has dared, although in the honest exercise of his duty, to remonstrate against abuses connected with his department, he has been quietly shelved, and a more pliant and obsequious person substituted in his place.

Now we are no friends to what is called centralization, and we have no desire to advocate the abolition of local authority. We are fully aware that a system which ramifies from a single source, and engrosses all patronage and all power in itself, is liable to very great abuse, and would perhaps eventuate in the establishment of a tyranny which would be justly abhorrent to the feelings of the British nation. But on the other hand, the uncontrolled exercise of local power tends to the establishment of a great number of petty tyrannies, instead of a single one, while in actual practice it leads, especially in scientific matters, to the commission of the most egregious

mistakes, and to the perpetration of an infinity of small but often scandalous jobs. The relations existing between the local Boards and the Medical Profession display in a striking manner the ignorance, the meanness, and the incapacity which too often prevail in the councils of the former.

We cannot for a moment suppose that the present horrible condition of the Metropolitan Workhouse Infirmaries has been sanctioned by the Medical Officers of those establishments, and indeed we know that in several instances the most urgent remonstrances have been made by them against the abuses which are now openly shown to exist. But, as we have above remarked, each local authority is a small tyranny in itself, and anything like an expression of the truth from a Medical Officer is regarded as an act of treason, and is liable to punishment by dismissal. Hence it is only natural that men should hold their tongues, when speaking would cost them their situations; and the Workhouse Medical Officers are compelled quietly to submit to evils which they have no power to remedy. As long as the Medical Officer extols the wisdom of the local Guardians, and remains contented with the foul air, the bad nursing, and the neglect which he finds in the so-called Infirmary wards, all is well and good; but as soon as he begins to show that drug-medication is not the only appliance for the restoration of the sick or the preservation from disease of the healthy, he is supposed to have gone beyond his province, and to be a legitimate mark for vulgar abuse, contumely, and opposition. Grocers and cheesemongers, and publicans and pawnbrokers—all of them, perhaps, men very respectable in their particular callings—who form the majority in most local Boards, become at once invested, by virtue of their office as Vestrymen or Guardians, with a sort of intuitive knowledge as to the causes, the prevention, and the treatment of disease, and they will argue with their Medical Officers on such points on a position of perfect equality. Nay more, on the principle that "fools rush in where angels fear to tread," they will pronounce dogmatic opinions upon the most difficult and mysterious questions in sanitary science, and will treat with ridicule and contempt all those whose modesty prompts them to caution and circumspection when dealing with such difficult themes.

Having thus expressed, without any reserve, our contempt for the conduct too often pursued in sanitary matters by the local Boards, it may be asked whether we have any advice to offer as to the inauguration of a better system; and we reply at once that we think the present organization, *if properly administered*, is quite adequate to produce a beneficial result. Without any necessity for building a number of enormous hospitals, each parish, or union of parishes, might be, and *can be*, compelled to furnish adequate accommodation for its sick poor, and the Medical and the nursing arrangements might be, ought to be, and *can be*, placed upon a more satisfactory footing. The Poor-law Board has been disgracefully supine in allowing a state of things which

it has always had the power to rectify, but which it has neglected even to expose, in consequence of an unworthy truckling to the local Boards. Without abolishing the rights of local government, the acts of the parochial Boards in sanitary matters ought always to be subject to the control of some competent superior authority; and there is no more interference with local independence involved in this proposition than is the right of trial by jury compromised by the well-known power of applying to the superior courts when verdicts are supposed to be wrong. As matters stand at present between Medical men and local Poor-law authorities, the former may be entirely in the right and the latter entirely in the wrong, and yet no appeal can be made in cases of disagreement, and the honourable Medical Officer is too often made to pay the penalty of his honesty. The contemptible policy of the Poor-law Board has hitherto been to take the part of the local Guardians, because they appeared to be the stronger party, and perhaps able to command some votes at the elections; but in any Appeal Court hereafter to be established, the Medical element ought to be distinctly recognized, and motives of mere policy or expediency should be entirely ignored.

MEDICAL TITLES.

“A ROSE by any other name would smell as sweet,” is a well-known, and almost a proverbial, phrase. In Medicine, however, it does not seem to be universally accepted as a truism. Men fight and write, and argue, and insinuate about Medical titles as though they were of the first importance; and all the while they are not agreed as to the meaning of the terms respecting which they dispute. We propose to address to our readers a few remarks on this subject; and first of all, we shall dilate a little on that word of hydra-headed interpretation—DOCTOR.

In its most broad and extended sense, this word is everywhere in the United Kingdom used to designate a Medical man as distinguished from a layman. Among people who make more or less pretension to education, it is limited to a Physician, as distinguished from a Surgeon; in Medical circles it is very generally applied to Licentiates of a College of Physicians, and Bachelors in Physic; while among the more strict sticklers for rank and status, it is given only to those to whom it is legally due:—to Doctors of a University.

So completely has the Doctorate become identified with the Profession of Physic, that few lawyers who hold the degree of LL.D. or D.C.L., prefix the “Dr.” to their names. A “D.D.” is mostly a “Rev.”; and is so distinguished in popular phrase from the Doctor Medical; a Graduate in Music is an academic exception; though a veritable M.B. or M.D., as the case may be, equally with his Medical brother; while no Bachelor in any of the faculties, save physio, ever dreams of assuming or of allowing himself to be styled by the title of Doctor.

In England Doctors in Physic are few: in Ireland

they are numerous; but in Scotland, their name is legio. From this it happens that in Scotland nearly every practitioner who calls himself M.D., has a legal right to the title. In Ireland, many have the degree, many have it only by professional courtesy, and many have it solely by popular diploma. In England the vast majority, while popularly spoken of as “the Doctors,” are not addressed as such; they have no claim to the title, and, for the most part, they clearly signify that they have no wish to be called by a name which does not properly belong to them.

Now, while we think that usage, or some other good reason, may often make it desirable for a man to drop a title which rightfully belongs to him—as when Dr. BUTT in the Consistorial Court is Mr. BUTT in ordinary high class legal practice; and Dr. ADAMS, in his capacity of University Professor, is Mr. ADAMS the eminent Surgeon before the public. Yet the opposite plan is not equally justifiable; and after all the fair and honest plan is for a man to call himself what he is, and not what he is not. We cannot, of course, hope to change the popular meaning of the word “Doctor,” nor do we wish to do so; but unless the usage of some body corporate, or some plainly defined rule, permit, we hold that a spade should be called a spade, and nothing else.

There is something dignified in a first-class Surgeon calling himself “Mr.” even though he be a Doctor; and there is something inexpressibly shabby in a Surgeon who is not a Physician usurping the title of the latter.

We have spoken of peculiar usages of Medical Corporations in this matter. The London College of Physicians distinctly repudiates giving the title of “Dr.” to any of its members or licentiates, as such; and so, we believe, does the Edinburgh College. The usage of the Dublin College is remarkable, and that there may be no mistake about it, we shall here give it in the form of an extract from the published Register of that body for the present year. At page 17 we thus read:—

“By ancient usage in this country, analogous to the title ‘Rev.’ in the case of a clergyman, and ‘Esq.’ in that of a barrister, the title ‘Dr.’ has always been applied to a physician as distinguished from that of ‘Mr.’ in the case of a Surgeon.

“Accordingly this College invariably applies the title ‘Dr.’ to its fellows, honorary fellows, and licentiates, whether graduate Doctors or not.”

From the foregoing, it would appear that members of the Dublin College are justified in using the professional prefixed title “Dr.,” while it is equally plain that they have no right to assume the academic M.D.

In Ireland it has always been the custom to give the courtesy title of Doctor to a Bachelor in Physic. This originated, if we may hazard a conjecture, on the same principle by virtue of which a Lieutenant-Colonel is commonly styled “Colonel,” and a commander in the Royal Navy “Captain.”

In these cases the Lieutenant Colonel and the Commander are really *the* men; and wherever they may serve under their superiors of analogous title, the latter are

looked on as more or less honorary officers, so far as their higher rank goes; the *work* is expected to be done by the others. Just so with the Bachelor in Physic in the older Universities; he differs from the Doctor only in his junior rank, and not at all in his professional qualification. The Bachelor is qualified to practise; the Doctor, on academic theory, is in addition licensed to teach (*docere*). This, however, is but a roundabout way of justifying a clearly wrong usage. We see nothing at all derogatory to the character or status of a Physician in his calling himself, for example, "Mr. JOHN PICKWICK, M.B.;" but to ordinary observers, it does sound not unlike usurpation that he should style himself "Dr. PICKWICK," and yet sign his name "JOHN PICKWICK, M.B." The number of Doctors of Medicine in the Universities of Oxford, Cambridge, and Dublin, is now very much greater in proportion to graduates from other places than it has been within the last century; and we confess it does seem a little unfair that the style and title of their degree, representing, as it does, a *triple* graduation should be taken by their juniors, who each and all can do as they did, and take the higher degree, when they are of sufficient standing to do so.

There is another point to which we may refer before concluding these remarks. When any graduate of Oxford, Cambridge, Dublin, Edinburgh, or London, signs M.D. or M.B. after his name he usually appends the name of the University from which he has his degree. Why do not all other graduates adopt a similar honest course? For many we cannot answer; but for many others we must say that they seem rather to shrink from informing the public to what Universities they belong. Thus we have one man signing himself "M.D. Dub., F.R.C.S.I." This is plain enough. He thinks both his qualifications highly creditable, and he is not ashamed of them. Another, however, signs himself "M.D., F.R.C.S.I." Why this difference? we ask. In many instances the only answer to be given is that M.D. is M.D., but as to any further particulars the less said the better. Now, all Universities in these kingdoms are legally equal so far as degrees go; the value of the education and qualification given by the different bodies must and always will vary; and so we must expect grades in the value of degrees, as in everything else in this world. We are convinced, however, that one large set of quack advertisements must come to a speedy end if we all sign after our degrees the place from which we have them. We have an advertising "Dr. SMITH," and any quack can with practical impunity call himself "M.D.;" but, as soon as the custom begins to run in the direction now advocated, the quack, if he wish to pass for the genuine article, must attach the name of some University to his title; and *then* we forthwith arrive at the state of things in which what was formerly every one's business, and therefore no one's, becomes the peculiar affair of some corporation, which, for its own sake, must fight it out with the usurper.

On the whole question, as before remarked, we think the profession should utterly oppose the assumption of titles which have no foundation in law or recognized usage; while, as to courtesy titles, we do not see why a spade should be called anything but a spade.

THE NEW VACCINATION BILL.

THE long and rather interesting debate on the motion of committing the Vaccination Bill in the House of Commons on Wednesday last, terminated by the Bill being referred to a Select Committee, with the full understanding, however, that the principle of the proposed measure was to remain untouched. Mr. H. BRUCE, in introducing the subject, made a very able speech, in which he traced the history of vaccination from its discovery to the present time, and showed, in the most conclusive manner, the necessity of passing stringent measures for the purpose of securing the efficient vaccination of the community. A great part of the debate was needlessly occupied by the recital on the part of some members of the foolish objections made by some ignorant persons against the practice of vaccination, and of course some jocularity was indulged in with reference to the Medical Profession; but on the whole, the tone of the different speakers was in favour of a more adequate remuneration to the vaccinators, the Government being rather blamed for parsimony in this respect than for undue liberality, and the comparative failure of compulsory measures for ensuring vaccination was in some degree attributed to the false notions of economy which have hitherto prevailed.

The Bill now introduced proposes to give the Poor-law Board additional powers to enforce the general practice of vaccination, to revise existing contracts, and to re-arrange the districts but it makes no difference in the rate of remuneration, and it leaves the superintendencies of vaccination practically in the hands of the local Poor-law Guardians.

Now it is impossible to conceive anything more absurd than to leave it to such persons, and we wonder why the Poor-law Board and the Guardians are not interested also with the nomination of the Bishops, or the command of the Channel Fleet, or the appointment of the judges, or the patronage of the Army, or the direction of the Bank of England, or any other office or duty which could be just as appropriate as the superintendence of a Surgical operation. It cannot be alleged that pauperism and vaccination are necessarily associated together, because it is expressly stated that the performance of gratuitous vaccination does not pauperize the person on whom the operation is performed, and it is most important to dissociate entirely the ideas of pauperism and vaccination, because while pauperism is properly discouraged, it is the duty of the State to encourage vaccination in every possible way. We state most unhesitatingly that the local Poor-law Guardians are utterly incompetent even to understand the principles on which the performance of efficient vaccination is founded, and

their gross ignorance of medical matters, their inherent love of petty jobbing, and their meanness in all that relates to the medical profession, make it imperatively necessary to relieve them from a duty which has been most inconsiderately imposed upon them.

We are not at all sorry that the Bill has been deferred for the present, and if it should be deferred altogether until the whole of the machinery of vaccination is removed from the control of the Poor-law, until a public prosecutor is empowered to inflict fines for non-vaccination, and until an efficient superintendence over the vaccinators is established, we shall not regret the delay.

THE VACCINATION (SCOTLAND) ACT.

FROM the Report of the Registrar-General in regard to the working of the Compulsory Vaccination Act during its first year, we learn the gratifying fact that only 2701 (2.71 per cent.) of all the children born during that year, amounting to 99,671 living children, remain unprotected by vaccination, and we also learn that during 1865 the number of deaths from small-pox sunk to less than one-half of the lowest number during the preceding ten years. It is obviously premature to connect the one fact with the other; indeed, knowing, as we do the wavelike manner in which the mortality from small-pox rises and falls, it would be absurd to attempt to do so until, from further experience, we obtain data sufficient to enable us to connect a certain percentage of unvaccinated children with a certain amount of mortality from small-pox. Years must elapse before we can obtain data sufficient for this, and after all we may well inquire, "Is this the object of the Vaccination Act?" And we unhesitatingly answer, "Certainly not." So long as one child can escape vaccination, and so long as there is no means of retrieving this failure, just so long there will be in this country a yearly increasing focus of contagion, the force and efficacy of which will only be ascertained as it is developed by the lapse of years. This, then, points to the first great defect of this Act, the impossibility of ensuring, by its provisions, the vaccination of *every child* born alive; without this the act, though not utterly valueless, is yet by no means so valuable as it might be. The maxim that if a thing was worth doing at all it was worth doing well, was early impressed upon us, and we think that Government would do well to remember that half measures are the bane of civilization, and that if it be worth while to compel all children to be vaccinated it is idle to say so without taking especial care that all shall be vaccinated. And there can be no difficulty about the matter; one or two inspectors of vaccination would very soon follow up the 2 per cent. of unvaccinated children and make sure of them. Till these are appointed the Vaccination Act is to a great and yearly increasing extent a dead letter.

There is still one other defect of this Act which requires redress, and it is this, that though compelling vaccination for the public weal, it yet leaves it to be paid for by private individuals, or to be performed gratuitously

as an act of charity by the medical man. Now, this is absurd; Government has no more right to compel my child to be vaccinated than to compel my cattle to be slaughtered, and if it wishes either to be done it must, or rather from our past experience we must say---ought to pay for them. In our large towns there are thousands vaccinated gratuitously at dispensaries who would find it a very great hardship indeed to raise even the one shilling and sixpence which is the statutory fee for the service; and in the Highlands and islands of Scotland many families pinch themselves to raise the by no means exorbitant statutory fee of three shillings and sixpence, because they know they shall otherwise be mulcted of the sum of twenty-one shillings, and even in the Lowlands many children of the poorer classes are vaccinated gratuitously to save those from a fine which would be simply ruin to one unable to raise eightpence. All this gratuitous vaccination, whether by private or dispensary physicians, indefinitely delays the solution of this question, and imposes another hardship on the shoulders of medical men, most of whose burdens are, like this one, self-imposed. Suppose gratuitous vaccination were to cease, would only 2 per cent. escape vaccination? I trow not. And I wonder how many of those vaccinated have been done in this fashion for the truth of which I can vouch. Parochial Boards and Inspectors do not always do their part of the work in carrying out the Act. A child in one of the parishes here of which I am vaccinator failed to have a certificate returned to the Registrar in due time. The Registrar is also Inspector, as is the case in many country parishes. The Registrar did not send an intimation of failure, but spoke to the father of the child (sec. xvii.). My son, in the meantime, vaccinated the child (as small-pox was somewhat prevalent), but refused to sign the certificate, as the father would not or could not pay the legal fee. This occurred some time since, and I have got no intimation, or rather order, from the Board (sec. xviii.) to vaccinate this child, or to give in a certificate of insusceptibility. By sec. xxvii., when the Parochial Board of any parish fails to perform its duty in carrying out the act the Board of Supervision steps in to enforce obedience; but who is to intimate failure to the Board of Supervision, particularly in such a case as this? Is it possible that this child could be registered as vaccinated without a certificate, on the personal knowledge of the Registrar? Or does it form one of the 2 per cent. unvaccinated—a position it has no actual right to occupy.

Some few parishes pay their vaccinator the statutory fee for all the children of the poorer classes born within their bounds; but this only renders it the harder for the inhabitants of those parishes not liberal enough to do likewise. If general vaccination be necessary for the public welfare, it is quite proper that the public should pay for it in every case; if it be not, it is absurd to attempt to enforce it. Meanwhile we may add that we think it very questionable policy for medical men to interfere in this matter; their obvious duty is to be true

to themselves, to cease from gratuitous work, and to insist upon a proper fee for each vaccination, leaving it to the paternal Government to find some means of at once protecting itself—that is, the whole body of the people—at the same time that it relieves those who feel themselves unduly burdened in having to pay for what they are compelled to have done whether they wish it or not.

The Vaccination Act was always regarded as a mere stopgap. In the very first report of its working its evils crop out; and these are of such a character as necessarily to go on increasing till remedied by another and more perfect enactment, which, so long as medical men supplement the present Act by gratuitous vaccination, will be postponed to the Greek Kalends, *Scottice*, “The morn come never.”

DEATHS OF DR. BABINGTON AND DR. HODGKIN.

Two well-known luminaries of medical science have just departed this life, amidst general expressions of regret, as they were no less distinguished for their high professional attainments than for their urbanity and genial disposition. Although both were verging on old age, they were still engaged in the active pursuit of their duties, the one in his practice in London, the other died while on a temporary sojourn with Sir MOSES MONTEFIORE, in the East. Their figures will be missed by those who were acquainted with the medical celebrities of the metropolis—Dr. BABINGTON, with his tall, slim, and gentlemanly form, in which the appearance of age was skilfully concealed; Dr. HODGKIN, with his long beard, strangely contrasting with his rigid Quaker attire. Both were men of distinction, Dr. BABINGTON having long held the position of Physician to Guy's Hospital, and Dr. HODGKIN having been for some time Professor of Pathology at the same institution. Dr. BABINGTON was at one time Pre-

sident of the Pathological and Epidemiological Societies; Dr. HODGKIN was the founder of the Ethnological Society, and was one of the earliest investigators of pathological science in the present century. Both were known as writers on medical subjects, Dr. BABINGTON having translated a work on the “Epidemics of the Middle Ages,” besides contributing a number of papers to the medical societies and to the medical journals; Dr. HODGKIN having written, among other works of merit, a well-known book on the “Pathology of the Serous and Mucous Membranes.”

SPIRITUALISM IN THE OLD BAILEY.

ON the occasion of a recent trial for libel at the Old Bailey, the DEPUTY RECORDER, in passing sentence, indulged in some remarks on spiritualism which excited some surprise in the public mind. He is reported to have said that, “for his own part, he was rather inclined to believe in spiritualism, *although he had seen nothing of it.*” This declaration of an inclination to believe in a system of which he knew nothing appeared so extraordinary, as coming from the judicial bench, that we do not wonder the learned functionary endeavoured to explain it away last week, which he did by attributing inaccuracy to the newspaper reporters. He said, as he now tells us, “that he could not say with the learned counsel (Sergeant BALLANTINE) that he was a universal sceptic, as for his own part he was rather inclined to believe; but of spiritualism he knew nothing whatever.” But the reporter of the *Times*, in a note appended to the DEPUTY RECORDER's explanation, maintains the strict accuracy of his report; and to make the matter still more complicated, Sergeant BALLANTINE denies that he expressed himself as being in any sense a universal sceptic, and asserts that his (Sergeant BALLANTINE's) scepticism relates only to spiritualism. So that Mr. Deputy Recorder CHAMBERS has not improved matters by his explanation, which only renders more obscure what was sufficiently unintelligible before.

NEW INVENTIONS.

SAVORY AND MOORE'S “REPTILE HEART” SYRINGE FOR ENEMA AND UTERINE INJECTION.

This apparatus acts by alternate contraction and dilatation, with a valve to direct the course of the current, thus resembling the action of a reptile's heart. It is very portable and occupies very little space, and is also very cheap. It consists of a flexible tube terminating at one end in an ivory nozzle, and opening at the other end into an india-rubber bag, and this latter again is adapted by means of another flexible tube to another bag of the same material. The first-named bag acts like a syringe, expanding and charging itself by its own elasticity, and

capable of being compressed and emptied by the pressure of the hand, and the other bag is a reservoir made to contain the fluid to be injected, and is easily detached when it becomes necessary to fill it. When only a moderate amount of fluid is required to be injected it may be contained in the reservoir; but if a larger quantity is necessary, the india-rubber entrance tube (not seen in the engraving) may be placed at once in the vessel containing the injection. Thus the amount of liquid employed can be varied to any extent, and the apparatus is equally

adapted for the administration of enemas or vaginal injections. It is easily cleaned by passing a little warm water through it. The instrument is designed by Messrs. Savory and Moore of New Bond-street, and is manufactured by Messrs. S. Maw and Son of Aldersgate-street, London, and the high reputation of both these firms will at once secure for the new invention the professional and public support which its ingenuity, simplicity, cheapness, and portability eminently deserve. It is inclosed in a small waterproof covering, and is very compressible, so that it is quite inconspicuous, and may be carried easily in the pocket.

Correspondence.

✂ We are not to be assumed to agree with the views of our Correspondents whose communications we insert for the purpose of affording opportunity for the enunciation of all shades of opinion in things medical. Our revision of letters is, therefore, confined to the removal of statements or expressions which we consider unsuitable or irrelevant to the subject in hand.

HOSPITAL NURSES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In a leading article, a few weeks since, in this journal, the above subject is well and ably brought under notice. Emboldened by the suggestion thrown out in the concluding clause, I take the liberty of addressing a few lines, which should you think worthy of insertion, will, I trust, serve to draw attention to a subject of so much importance. Conversant with the routine of metropolitan hospitals for some years, I can bear witness to the difficulty, nay impossibility of obtaining good nurses for the sick, and I well remember one institution in this city having to depend on the services of *one paid nurse alone* for more than two months, and how she ever got through the duties of daily attendance on upwards of seventy patients (male and female) is a mystery to me; but such was the difficulty experienced in procuring suitable persons the board had to defer appointing nurses for more than two months.

As to the "religious" aspect of the subject, both in this city and in London, I think most people will concur in the well-earned and deserving praise bestowed on the "sisterhood;" but, although not entirely agreeing with Miss Nightingale, that "the idea of the 'religious order' is always more or less to prepare the sick for death," still I think on other grounds this system is not applicable to most of the institutions in our city. Therefore, some other method must be devised which would effect the desired end, and would it not be advisable to train young women as nurses *as a profession*. This I conceive may be accomplished in one of two ways; first, by receiving into our hospitals young women of good character as apprentices under the head nurse, and discontinuing the present practice of ward maids. This might be done if, as an inducement, good wages and a comfortable home were guaranteed to the pupil when the period, say four years, of apprenticeship had expired. If this were done, I believe many young girls who at present seek by emigration to better their condition, or crowd the offices for servants in this city, would be only too glad to take advantage of the system, and we would have hereafter no lack of trained nurses capable of attending on the sick in the way it should be done.

The second method I would suggest, though very desirable, is perhaps not so feasible; it is the establishment in the vicinity of the city of a convalescent home or sanatorium, which, while it would confer a boon on the profession by permitting removal of cases not requiring further medical treatment from the hospital wards, thus giving room for

other urgent ones which at the present day have reluctantly to be refused admittance owing to the want of space; to the public in preventing the possibility of infection being carried from the hospital ward into the family circle, and effecting a quicker and perhaps more permanent cure on the sick patient; and, finally, would solve the problem of training hospital nurses by affording a *nidus* where the inherent gentleness of the sex might be taught to soothe the bed of pain, and even rob the fell-destroyer of half his terrors. Apologizing for trespassing so far on your valuable space, and hoping soon to see in our neighbourhood what your Edinburgh and Birmingham Correspondents announce (in the paper I have referred to) being accomplished in the sister isle with a large staff of young nurses in full training, I remain, yours faithfully,

JOHN S. A. CUNNINGHAM, L.R.C.S.I., L.K.Q.C.P.I.
Rathmines, April 12, 1866.

AMENDMENT OF THE MEDICAL ACT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am glad to see by this week's issue that an Amendment of the Medical Act is in contemplation, and I hope the profession will respond to your call, and second the able efforts of THE PRESS AND CIRCULAR in obtaining insertion of clauses which shall protect the legitimate practitioner and not the quack, as the present useless and inoperative measure does. We were told by the optimists that the Registration Act of 1859 would raise the status of the medical profession immensely and demolish quackery. Well, Sir, the very opposite has been the result, and the latter vice was never more rampant than at present. The proposed Amendment of the Medical Act will certainly be a step in the right direction, as it will prevent unqualified and unregistered persons assuming medical titles; but that will not deter the quacks in the least. What more easy than to drop the title of Doctor, Surgeon, or Professor, and traffic on the ills of humanity as before. Until an act is passed prohibiting ignorant and unqualified individuals undertaking the treatment of disease and dispensing of drugs, all the efforts of the Medical Council will fail in purging these kingdoms of quackery. I am sure our profession is of much greater importance to the community than the "legal;" nevertheless, the safeguards in the former are few and imperfect, in the latter numerous and secure. If the Medical Council have wasted a great deal of time and money heretofore with little benefit to the profession, at present good service is being done in erasing obnoxious names from the Registry, and I beg to suggest to the members of that body the desirability of placing in the same category those gentlemen who disgrace their profession by meeting quacks in consultation.—I remain, dear Sir, yours very truly,

CHAS. GARLAND, L.K.Q.C.P.I., L.R.C.S.I.
Newry, April 7, 1866.

Parliamentary Intelligence.

HOUSE OF COMMONS.—APRIL 9TH.

THE PROMOTION OF ASSISTANT-SURGEONS IN THE GUARDS.

THE Marquis of HARTINGTON said, in reply to Mr. O'Beirne, that up to the time of the warrant in 1858 the system of promotion in the Guards was, no doubt, a regimental system; but in that year a warrant was issued which conferred several advantages, as to pay and rank, on the medical department, and that warrant also recommended that the mode of promotion, as a general rule, for the rank of assistant-surgeons should in future be by seniority in the service. In 1860 the question arose in regard to the surgeons of the household cavalry, whether the pro-

visions of the warrant would apply to that branch of the service, and it was decided by her Majesty, on the recommendation of the Commander-in-Chief to the Secretary of State for War, that in the household cavalry and in the Guards also, in consideration of the surgeons having accepted the warrant, they should enjoy the advantages it conferred upon them.

THE CATTLE PLAGUE ACT.

Sir G. GREY said, in reply to Mr. C. Read, that the provisions of this Act had been merely temporary, but an order in council had been passed to continue those provisions with regard to the slaughtering of animals and the payment of compensation to the 10th of May.

CONTAGIOUS DISEASES BILL.

On the motion of Lord C. PAGET, the following members were nominated the select committee on this Bill:—Lord Clarence Paget, Sir John Pakington, Mr. Walpole, Mr. Hunt, Lord Hotham, Sir James Fergusson, General Peel, Sir Harry Verney, Admiral Erskine, Sir Morton Peto, Mr. Ayrton, Mr. Kinnaird, Mr. Locke, Marquis of Hartington, Sir George Grey, Colonel Herbert, and Mr. Morley.

APRIL 10TH.

MORTALITY OF TROOPS IN CHINA.

On the motion of Colonel NORTH, the following gentlemen were appointed a select committee on the mortality of troops in China:—Colonel North, the Marquis of Hartington, Lord Hotham, Mr. Baxter, Mr. Adderley, Lord F. Cavendish, Mr. Roebuck, Colonel P. Herbert, Mr. Dalglish, Lord H. Percy, Mr. Calthorpe, Major Anson, Lord J. Hay, Mr. Trevelyan, and Major O'Reilly.

PROMOTION OF SURGEONS IN THE GUARDS.

Sir R. ANSTRUTHER gave notice that on the 16th of May he should call the attention of the House to the proposed alterations in the system of promotion amongst the medical officers in the brigade of Guards, and that he should move for a copy of the Warrant or order of 1860, under which the alteration was made.

APRIL 11TH.

The Cattle Contagious Diseases Bill and the Labouring Classes Dwellings Bill were read a third time and passed.

VACCINATION BILL.

Mr. H. BRUCE, in moving the committal of the Vaccination Bill, after sketching briefly the history of vaccination, and the legislation in regard to it, and quoting copiously from numerous medical returns and reports to illustrate its efficacy in checking the spread and virulence of small-pox, described in detail the defects of the present system, which the Bill was intended to remedy. The Bill, he explained, besides consolidating the existing law, would enable the Poor-law Board to re-arrange districts and revise contracts periodically; it would provide for more complete and permanent registration, and would give increased facilities to Boards of Guardians to enforce an universal system of vaccination.

Mr. HENLEY, in criticizing the Bill, pointed out two principal defects—the want of security for a due supply of healthy lymph, and the inadequate payment of the medical officers, to which last cause he attributed the comparative failure of the system of compulsory vaccination.

Sir R. PEEL agreed with Mr. HENLEY in censuring the niggardly payment allowed to the vaccinators, and enumerated nine or ten clauses in the Bill which he predicted would be inoperative. He suggested that it should be postponed to give time for further consideration.

Mr. LEWIS moved that the Bill be referred to a Select Committee, and this amendment was seconded by Sir J. C. JERVOISE, and supported by Lord HENLEY, Mr. BARROW, and other members.

After some further discussion,

Mr. BRUCE consented to refer the Bill to a select committee, but upon the express understanding that the committee were not to interfere with the principle of the

measure, which was the establishment of a compulsory and efficient system of vaccination.

The Bill was then ordered to be referred to a select committee accordingly.

On going into committee of supply—

Mr. McEVoy—That in the opinion of this house, her Majesty's Government should now adopt the recommendations of the Select Committee of 1858, which recommended "her Majesty's Government to take into consideration the claims of Ireland to a grant of the half cost of medical officers of unions, with the view of providing for the same in future, as is now the practice in England and Scotland," fortified as such recommendation is by the report of the Select Committee on Taxation of Ireland in June, 1865, who reported that with regard to the grants for Poor-law Medical Officers and Workhouse Schoolmasters, "it would be reasonable that the same aid should be extended to Ireland as is already extended to England."

THE CATTLE PLAGUE IN MIDDLESEX.

Mr. DUCANE asked the Secretary of State for the Home Department whether his attention had been called to what took place at the Middlesex Sessions, held yesterday, with regard to the cattle plague. A Mr. Glossop was represented to have said, in moving for a rate of a penny in the pound to meet the expenses of compensation, that he regretted to have to state that the cattle plague was increasing in the county. Great ravages had occurred in consequence of the introduction of diseased Dutch cattle in the ship *Mars*, which were landed at Blackwall, and taken through the metropolis to the extreme verge of the county and smuggled in by the agents of Lord Granville and Lord Taunton. He wished to ask whether the right hon. baronet would inquire into this, and if he were convinced it was true, whether he would devise some remedy against a similar affair taking place.

Sir G. GREY said he had first heard of this only about five minutes ago, and he was unable to answer the question as he knew nothing of the circumstances. He thought there must be some misstatement, but he would take care to inform himself of the facts, and he would then be in a position to lay the information before the house.

The annual meeting of the shareholders of the Briton Medical and General Life Association was held on Saturday last, presided over by Dr. G. H. Barlow. A most satisfactory report was presented, as it showed that 2769 policies had been issued during the year, assuring £829,926, and yielding in new annual premiums the sum of £25,200; and, further, that out of the gross income of £171,994, after payment of claims and other outgoings, the sum of £70,631 remained as a balance to be added to the reserve fund. A dividend of eight per cent. was declared.

EARLY BRITISH SKELETON.

In the autumn of last year, near Malton, the North-Eastern Railway Company commenced the formation of cofferdams on each side of the river. In the first formed, on the Malton side, as reported at the time, after ten feet of the fluviatile post-tertiary clay had been excavated, a three-foot bed of alluvial silt was entered, which abounded with water, and caused the cofferdam to burst. Beneath this sand was the Kimmeridge clay of the Vale of Pickering, and upon it, at a depth of thirteen feet, the femoral and pelvic bones of a human being were thrown out, the skull then being left within the piles forming the dam. An enlarged dam having been formed, operations were recommenced last week, when the skull so much desired was fortunately obtained, and is now deposited in the collection of pre-historic *crania* of the Rev. William Greenwell of Durham. The bones, from long steeping, have become blackened and devoid of lime, resembling leather more than bone, and are much impregnated with vivianite. The body has been that of a male of small stature, apparently from 40 to 45 years of age. The teeth have all been present, and are not much worn, but the sagittal suture of

the skull is almost obliterated, and so is the coronal suture. It has been supposed that the body was one of an early British race, but the skull is not at all typical, and not in the least like those obtained from either the long or the round barrows of the Britons. It is very broad in the occipital region, and rather narrow in the frontal: but the main characteristic is flatness. Mr. Greenwell says the skull is very like some he has from a Kentish Roman cemetery, but is relatively broader in the occipital region. He can offer no conjecture as to race, but the supposition that the man may have been a dependent on the Romano-British camp at Malton, probably an auxiliary. This view is strengthened by the finding in another excavation, but on the other side of the river, and also below the clay and silt, a rudely-formed vessel upturned.—*Times*.

Meetings of Scientific Societies.

GEOLOGICAL.—March 21.—The following papers were read:—"On the Fossil British Oxen: Part I., Bos Urus, Caesar," by Mr. W. B. Dawkins.—"Further Documents relating to the Formation of a New Island in the Neighbourhood of the Kamen Islands," by Commander G. Tryon.—"Note on the Junction of the Thanet Sand and the Chalk, and of the Sandgate Beds and Kentish Rag," by Mr. T. McKenny Hughes.—"On the Lower London Tertiaries of Kent," by Mr. W. Whitaker.

ROYAL SOCIETY OF LITERATURE.—March 21.—Sir Patrick Colquhoun, LL.D., in the chair.—Mr. Vaux read a paper, communicated by Mr. Fox Talbot, V.P., "On the Translation of the Clay Cylinder called that of Bellino," containing the annals of the two first years of the reign of Sennacherib. The two principal subjects of these annals are the successful campaign against Merodach Baladan, the King of Babylon, who is noted in the Bible as having sent presents to Hezekiah, when he heard that the Jewish king had recovered from a fit of sickness; and the building of a new magnificent palace at Nineveh, together with a restoration of the city itself. The war with Merodach Baladan is described very graphically, the details of many passages being capable of illustration from the sculptures in the Koyunjik Gallery at the British Museum; while, in the same room, we find Sennacherib presiding over the preparation and construction of great works, which may fairly be supposed to represent either this new palace at Nineveh or, at all events, some other great building in Assyria. Mr. Vaux pointed out to how great an extent this cylinder might be taken as a description of the sculptures which were procured by Mr. Layard during his last visit to Nineveh, and added several notes in confirmation of Mr. Talbot's translation.

BRITISH ARCHAEOLOGICAL ASSOCIATION.—March 28.—J. R. Planché, Rouge Croix, V.P., in the chair.—Mr. J. W. Bailey exhibited an ancient iron dagger, excavated from the railway works near to Barclay's brewery, in Southwark, the handle and blade in one; also an iron trident found in Southwark, and pronounced to be the weapon of a Roman gladiator. The same gentleman exhibited a curious ancient hammer-head made of stag's horn, and a vase or bottle of late Roman or early Saxon fabric, remarkably formed.—Mr. Brighthouse exhibited a vase of Peruvian fabric.—Lord Boston exhibited a photograph of the famous Lee penny, which his Lordship had with much trouble obtained. The coin in which the gem is set has been termed a Byzantine coin, a shilling and a penny. The proper description of the coin it was his wish to determine; and the photograph proves it to be an English groat, temp. Edward III.

LINNEAN.—March 15.—The following papers were read:—"Account of a *Lusus Naturæ*, a Double-headed Indian Water Snake," by Dr. J. Shortt.—"Descriptions of Six New Species of Simple-fronded Hymenophyllaceae," by Mr. J. G. Baker.—"*Lichenes Amazonici et Andini*," by the Rev. W. A. Leighton.

ANTHROPOLOGICAL.—April 3.—The following papers were read:—"A New Reading of Shell-mounds and Graves at Keiss, near Wick," by Mr. J. Cleghorn.—"On Human Remains at Keiss," by Mr. R. J. Shearer.—"On Human Remains at Keiss," by Mr. J. Anderson, Mr. G. Petrie, and Dr. J. Hunt.

ZOOLOGICAL.—March 27.—A letter was read from Dr. G.

Bennett, giving details concerning the habits of the Lyre Bird (*Memura Nova Hollandiae*) in captivity.—The Secretary communicated an extract from a letter addressed to him by Dr. Schlegel, concerning the correct localities of the different species of Cassowary.—Dr. Murie and Mr. St. George Mivart communicated a joint memoir on the anatomy of the Lemuroidea, principally relating to the myology of these animals.—Mr. Selater and Mr. Salvin read a catalogue of birds collected by Mr. E. Bartlett during his recent expedition up the River Ucayali, in Eastern Peru, with notes and descriptions of the new species. The total number of specimens contained in Mr. Bartlett's collection was about 700, referable to 252 different species, of which 12 proved to be new to science.—Mr. A. G. Butler communicated a supplement to his monograph of the genus *Danais*, lately read before the Society, founded on specimens in the collection of Mr. O. Salvin.—Dr. J. E. Gray gave a notice of an apparently new species of Monkey of the genus *Cercopithecus*, living in the Society's Menagerie, and proposed to be called *C. erythrogaster*, and a notice of a new species of *Nasua*, from South America, proposed to be called *N. dorsalis*.—Dr. Gray also pointed out the characters of a new species of *Spatangus* in the collection of the British Museum, which he proposed to call *S. variegatus*.

ON THE USE OF THE BROMIDES OF POTASSIUM, CADMIUM, AND AMMONIUM IN THE TREATMENT OF INSANITY.

THE experiments related in this paper were instituted by Dr. Belgrave of the Lincolnshire County Asylum, chiefly to ascertain the therapeutic value of the bromides in the treatment of general paralysis, and they seem to show the possibility of controlling some of the more serious occasional manifestations of that disease, as also similar symptoms in other forms of mental disorder. Fourteen cases of general paralysis were treated with the bromides of potassium and ammonium with variable results; but the general effect of the bromides appeared to be to tranquillize the system. Eleven cases of epilepsy were also subjected to treatment by the bromides, the patients being selected in consequence of their extreme irritability and proneness to violence. The results did not prove that these drugs have the power to diminish permanently the number or the severity of the fits, but they afforded evidence of their influence in allaying some of the most violent manifestations of the disease. The bromide of cadmium was tried in eleven cases of mania, with a view to relieve severe temporary excitement, and in doses of one grain it was found to exert a very rapid and powerful effect, causing abundant vomiting and some purging, diminution in the force of the pulse, and temporary mental quietude, bordering on depression. Dr. Belgrave concludes, from his observations, that the bromide of potassium is antiphlogistic, and a sedative to the cerebro-spinal functions; that it subdues the force of the pulse and induces loss of flesh and debility, and that it exercises a powerful temporary effect over the number of fits in epileptic cases. The bromide of ammonium resembles the bromide of potassium in its action, but is less powerful, and does not induce emaciation or general depression. The bromide of cadmium is probably an irritant to the mucous membrane of the alimentary canal, its brief but marked calmative effect being principally the depression following the action of a powerful emetic and purgative. The action of this drug resembles that of tartar emetic or sulphate of zinc, but it has treble the power of the former and twelve times that of the latter (*sic*). It is said by Dr. Belgrave to be exceedingly useful in severe exacerbations of mania.—*Journal of Mental Science*.

COLCHICIN AND COLCHICEIN.—Dr Huebler has examined this poisonous alkaloid. He finds its best precipitant to be tannic acid. Treated with strong sulphuric acid it is converted into *Colchicin*, an isomeric nitrogenous body, of a slightly bitter taste and acid nature. It combines with soda, baryta, and oxide of copper to form crystalline salts.—*Year-Book of Pharmacy*.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 10th inst., and when eligible will be admitted to the pass examination:—

J. L. Moseley, A. H. Baines, C. J. Scels, F. S. Daldy, Charles Munden, J. G. Carruthers, W. B. Lewis, C. J. Worts, George Stokell, W. J. Bennett, J. W. Barry, William Kipling, John Lloyd, J. J. Bingham, William Price, David Havard, C. H. Joubert de la Ferté, Innan Welsh, Friend Lewin, T. A. Roberts, R. C. Sanders, W. H. Causton, George Salt, W. J. Barkas, T. O. Wood, J. T. Parkinson, W. A. Cox, Edward Jackson, T. W. Lee, H. L. Snow, William Dobson.

The following passed their examination on the 11th inst.:

Edward Hower, R. M. Bradford, J. T. Williams, C. B. Crowfoot, N. H. Jarvis, George Andrews, Richard Rendle, R. L. Wilson, J. G. Wiseman, J. B. Saundry, Frederick Taylor, Edward Sunderland, A. H. Buck, Adam Wilkinson, William Powell, Edward Stephens, William Youngusband, J. R. Haynes, C. C. Winckworth, H. E. Hetting, T. D. Saunders, George Thompson, F. W. Wimberley, John Bately, Clement Dukes.

The following passed on the 12th inst.:

William Roche, John Currow, A. F. McGill, Daniel King, Wm. Webster, W. B. Kendall, John de Liefde, T. W. Joy, F. W. Salzuann, Branford Edwards, R. M. Cole, Charles Higgins, J. A. Lormier, Alex. McGregor, John Gosse, D. H. B. Anderson, John Giles, William Anderson, N. C. Dobson, John Fairbank, Alfred Hollis, J. J. Swindell, Walter Maine, J. G. Black, B. P. B. Burroughs, Anthony Foster, Evan Williams.

It is stated that of the 108 candidates who offered themselves for examination, 5 were rejected on the first day, 8 on the second day, and 9 on the last.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following gentlemen having been duly examined, received letters testimonial in the month of March:—

Anster, William Blacker, Dublin.
Doyle, Patrick O'Connell, Milltown, Dublin.
Weir, John, Portadown, county Armagh.
De Merick, Eugene, Dublin.
Park, Duke, Ballywilliam, county Fermanagh.
Knox, Martin, Dublin.
Begg, Joseph Thomas, Dublin.
O'Leary, William Patrick, Charleville, county Cork.
Bolster, Thomas, Summerville, Mallow, county Cork.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 5th inst.:

Macgownan, Alexander Thorburn, Caversham-road, N.W.
Pratt, William Thomas Cassell, Newport, Monmouthshire.

The following gentlemen also on the same day passed their first examination:—

Barroll, George William, St. George's Hospital.
Bately, John, Sydenham College, Birmingham.

MR. HERMANN OTTO POST, lately deceased, has left a legacy of £100 to the German Hospital.

A YOUNG man died of hydrophobia in the neighbourhood of Manchester, after two days' illness, on Wednesday last. He was bitten in the leg by a bull-terrier in August last.

At the London Quarter Sessions, on Saturday week, a report of a committee was adopted, increasing the salary of the city coroner to £885 a year.

MR. H. EDWARDS, Surgeon to the Cardiff Workhouse, has been charged with manslaughter: two men having died after taking some medicine for which they had applied to the workhouse surgery.

The gross income of Christ's Hospital for 1865 amounted to £71,855 11s. 10d. Of this the medical officers of London and Hertford received £745. The average number of boys maintained and educated in the London and Hertford establishments was 1205.

MR. PEALE of Maidstone, has offered to the Town Council of that borough £1000 to purchase a healthier site for the Grammar School.

DR. HILLIER, in his report to the vestry of St. Pancras, stated that only one fatal case of small-pox had occurred in the parish, but that ten cases were under the care of parochial surgeons. The Small-pox Hospital is quite full.

A FALSE report has been spread that trichiniasis had

appeared in Chicago; the object being to favour speculation in the meat trade.

THE Duke of Cambridge will preside at the annual festival of the University College Hospital on the 18th inst. at Willis's-rooms.

THE old College of Physicians in Warwick-lane, which was built by Sir Christopher Wren, is to be pulled down in a few days.

ROYAL IRISH ACADEMY.—Lord Talbot de Malahide, the newly elected President of the Royal Irish Academy, has appointed the Very Rev. Dean Graves, the ex-president; Sir W. R. Wilde, M.D., Rev. Geo. Salmon, S.F.T.C.D., and Professor W. K. Sullivan, C.U., Vice-Presidents of the Academy.

ACCORDING to a report prepared by Dr. Percy since the session began, it is stated that the system of ventilation adopted in the Houses of Parliament is that of exhaustion, the air being put in motion by means of heat, applied by coke fires in great upcast shafts, the chief two being in the Victoria Tower and the Clock Tower.

THE Constantinople Cholera Conference have agreed upon a plan of procedure. It groups the questions to be considered into four classes: 1, the nature and origin of cholera; 2, its transmissibility; 3, the measures of prevention against it; and 4, the form to be given to the resolutions of the conference.

AN ALKALOID IN RHATANY.---Wittstein has obtained, from an extract of American rhatany, an alkaloid, apparently identical with tyrosine; an analogous result has been obtained by M. Ruge, excepting that he regards the alkaloid as distinct, and differing from tyrosine, by two atoms of carbon.—*Year-Book of Pharmacy.*

RECIPROCAL ACTION OF CREAM OF TARTAR AND SULPHATE OF LIME (BUSSY AND BUIGNET).—It has long been the custom of wine-makers to put gypsum into their wine before or after fermentation. The result of this addition may or may not be pernicious, most probably it is not. MM. Bussy and Buignet, on bringing sulphate of lime into contact with bitartrate of potash, in an alcoholic mixture, found that the results were neutral tartrate of potash, tartrate of lime, and bisulphate of potash.—*Year-Book of Pharmacy.*

FERRUM REDACTUM (OBERLANDER).---The author analyzed a sample of reduced iron, and found it to contain only five per cent. of metallic iron, the rest being protoxide with sulphide. He surmises it to have been the wasted residue from the preparation of cyanide of potassium according to Liebig's process.—*Year-Book of Pharmacy.*

MORTALITY IN CHILDREN.---Out of 100 children born in Norway, 83 attain the age of five years; in Sweden, 80; in Denmark, 80, including Schleswig and Holstein, down to the Elbe, the country of the Angles of old; in England, 74; in Belgium, 73; in France, 71; in Prussia, 68; in Holland, 67; in Austria, 64; in Spain, 64; in Russia, 62; in Italy, 61. Thus the chance is always in favour of the life; but here it is 8 to 2, there only 3 to 2. What is the proportion of deaths under the age of five out of 100 children that see the light? In Norway, 17; Denmark, 20; Sweden, 20; England, 26; Belgium, 27; France, 29; Prussia, 32; Holland, 33; Austria, 36; Spain, 36; Russia, 38; Italy, 39.

DETECTION OF SANTONINE IN URINE (NOTTA).---When santonine is taken before bed-time, the urine next morning will be found to turn a cherry-red on the addition of liquor potassæ, even without heating—an indication similar to that of diabetic sugar.—*Year-Book of Pharmacy.*

TEST FOR THE PURITY OF ESSENCE OF MUSTARD.---The oils most frequently used to adulterate essence of mustard become brown or red in the presence of concentrated sulphuric acid, while the pure essence dissolves in it. Five drops of the essence with 50 drops of concentrated sulphuric acid should be introduced into a small tube and shaken together. If the essence is adulterated, the coloration will at once become apparent. Should rectified petrolenm be present, the acid will not colour it; but it may be recognized by its insolubility in the acid floating in the form of a limpid oil.—*Year-Book of Pharmacy.*

Notices to Correspondents.

The Royal Institution.—The notice has been received.
Mr. R. D.—We have not noticed the case because we suspect that both parties really belong to the same fraternity, and if so, it is better to let them settle their disputes themselves. We cannot find the name of either in the Medical Directory, but that of one of them is well known.
X. Y. Z.—The term "haloid salt" signifies a salt having an analogous constitution with that of sea salt.
Mr. T.—We have received the pamphlet, but we regard it as only a puff.

POOR-LAW MEDICAL SERVICE.—VACANCIES. ENGLAND.

Chard Union.—First Ilminster District; area 7032; population 4608; salary, £68 ss. 4d. per annum.
Driffield Union.—Killham District; area 13,880; population 2035; salary £16 per annum.
Hartley Wintney Union.—Heckfield District; area 7759; population 1492; salary £70 per annum.
Kingsham Union.—The Workhouse; salary £50 per annum.
Uppingham Union.—Barrowden District; area 16,874; population 3887; salary £45 per annum.
Wexham Union.—Fourth District; area 15,941; population 3299; salary £25 per annum.
Width Union.—Abergwessin District; area 68,480; population 3784; salary £42.
Penbridge Union.—Brewod District; area 20,721; population 5629; salary £50.—Workhouse.—Salary £20.
Banbury Union.—Hornton District; area 9740; population 3062; salary £61 ss.
Bridgewater Union.—Chilton Polden District; salary £50.

IRELAND.

Westport Union.—Islandeady Dispensary; election May 4; salary £75; vaccination and registration fees about £25.
Devlin Union.—Clonnellon Dispensary; election May 2; salary £80.

MEDICAL VACANCIES. ENGLAND.

Leeds Sanitary Inspector.—Salary £500 a year; election May 9.
West London Hospital, Hammersmith.—Resident Surgeon.
Samaritan Free Hospital.—Physician for out patients.
Northampton Infirmary.—Assistant House-Surgeon; salary £50, with board, &c.
Sheffield Public Hospital.—House-Surgeon; salary £100, with board, &c.—Assistant House-Surgeon; salary £65, with board, &c.
Stockport Infirmary.—Assistant House-Surgeon; salary £50, with board, &c.
Worcester Dispensary.—Resident Medical Officer; salary £100, with two and a half per cent. on the subscriptions, and with apartments.
Carmarthen Lunatic Asylum.—Assistant Medical Officer; salary £100, with board, &c.; candidate must speak Welsh.
Margaret-street Consumption Infirmary.—Visiting Physician.
Stamford Hill Dispensary.—Assistant Medical Officer; salary £40, with board, &c.
Iste of Man Hospital.—Resident Medical Officer; salary £75, with rooms, &c.
Wivelscombe Dispensary, Somerset.—Medical Officer; salary £50, with a house.

MEDICAL APPOINTMENTS. LONDON.

W. R. ROGERS, M.D., Physician for In-Patients to the Samaritan Free Hospital.
WM. HICKMAN, M.B., Surgeon for Out-Patients to the Samaritan Free Hospital.
F. E. JUNKER, M.D., Physician for Out-patients to the Samaritan Free Hospital.
FISH, R., M.R.C.S., Assistant-Surgeon to the London Rifle Brigade.
GRUBB, R.T., M.R.C.S., House-Surgeon to St. Mark's Hospital.
HAYWARD, SIDNEY, M.D., M.R.C.S., Honorary Medical Officer to the Royal Pimlico Dispensary and Lying-in Charity.
MURRAY, W. BOYD, M.B., M.R.C.P., Physician to the North London Hospital for Consumption.
PAGE, W. J., M.R.C.S., Surgeon to the Peckham Rye Dispensary.
A. W. WILLIAMS, M.D., Physician for Out-Patients to the Samaritan Free Hospital.
DE TATHAM, H., L.R.C.P., M.R.C.S., House-Surgeon, to St. Mary's Hospital.

PROVINCIAL.

BOTTLE, A., M.D., Senior Resident House-Surgeon to the Leeds Public Dispensary.
BUTLER, T. M., M.R.C.S., Honorary Assistant Medical Officer to the Surrey County Hospital, Guildford.
COOKSON, E., L.S.A.L., Resident Assistant House-Surgeon to the Leeds Public Dispensary.
ELLERTON, JOHN, M.D., Surgeon to the North Riding Infirmary, Middlebro'-on-Tees.
RIDGEN, G. W., M.R.C.S., House-Surgeon to the Taunton and Somerset Hospital.
SCHOLLICK, T. J., M.R.C.S., Honorary Assistant Medical Officer to the Surrey County Hospital, Guildford.
MORTON, J., M.B., Honorary Assistant Medical Officer to the Surrey County Hospital, Guildford.
VEITCH, WILLIAM YOUNG, L.R.C.P. Edin., House-Surgeon to the North Riding Infirmary, Middlebro'-on-Tees.

J. H. QUIN, M.R.C.S.E., House-Surgeon and Apothecary to the Lincoln General Dispensary.
P. Q. KARKEK, M.R.C.S.E., House-Surgeon to the General Infirmary, Chester.
J. TAYLOR, M.R.C.S.E., Assistant House-Surgeon to the General Infirmary, Chester.

IRELAND.

T. S. MURRAY, L.K.Q.C.P.I., Medical Officer for the Manorhamilton Dispensary District, has been elected Medical Officer for the Tobercurry Dispensary District of the Tobercurry Union, vice J. M. McCarthy, M.D., deceased.

SCOTLAND.

SIMPSON, J., L.R.C.P. Edin., has been appointed to the Leith Hospital and Edinburgh Humane Society and Dispensary.
J. GODFREY, L.R.C.S. Edin., has been elected Assistant Medical Officer to the Barnhill Poorhouse, Glasgow, vice J. Taylor, M.D., deceased.

Births, Deaths, and Marriages.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

BIRTHS.—ENGLAND.

BUCHANAN.—On April 7, at 63, Harley-street, the wife of G. Buchanan, M.D., of a daughter.
FITCH.—On April 5, at Chaddeley Corbett, near Kidderminster, the wife of F. Fitch, M.D., of a son.
FRITZPATRICK, JOHN.—On March 31, at 39, Elgin-road, Kensington-park-gardens, the wife of John Fitzpatrick, M.D., retired Surgeon-Major, Madras Army, of a son.
GAMGEE, J. S.—On March 31, at Birmingham, the wife of J. S. Gamgee, M.R.C.S., of a daughter.
GELL.—On March 27, at Great Aycliffe, the wife of A. S. Gell, M.R.C.S., of a son.
HARVEY.—On April 7, at 31, Grosvenor-street, the wife of John Harvey, M.D., of a son.
MACANN, A. B.—On April 5, at 22, King-street, Portman-square, the wife of A. B. Macann, M.R.C.S., of a son.
MORPHEW.—On April 8, at Sevenoaks, the wife of A. Morpew, Staff-surgeon, of a daughter.
PERKINS.—On April 2, at Bentinck-terrace, Regent's-park, the wife of R. H. Perkins, Surgeon, Bengal Army, of a son.
RUSSELL.—On April 5, at Acreington, Lancashire, the wife of W. S. Russell, M.R.C.S., of a son.

SCOTLAND.

ADAM.—On April 2, at 137, Princes-street, Edinburgh, the wife of H. Adam, Assistant-surgeon, Madras Army, of a son.
CALDWELL.—On March 28, at Dregghorn, Arvshire, the wife of J. Caldwell, L.R.C.P. Edin., of a daughter.
McQUIBBAN.—On the 28th ult., at Constitution-street, Aberdeen, the wife of Dr. McQuibban, of a daughter.
NEILSON.—On the 2nd inst., at Blairgowrie, Perthshire, the wife of J. Neilson, M.D., of a son.

IRELAND.

WILMOT.—On the 2nd inst., at Merrion-square, North, the wife of S. G. Wilmot, M.D., of a daughter.

MARRIAGES.

DRAKE-ELLIOT.—On April 4, at All Saints', West Ham, T. Drake, M.R.C.S., to May, daughter of W. Elliot, M.D.
PEGGLEY-OATWAY.—On April 5, at Old Cleeve, Somerset, L. Pugsley, M.R.C.S., to Susannah Risdon, daughter of the late R. Oatway, Esq.
WARD-BURNAND.—On April 10, at Cuckfield, W. P. Ward, Surgeon, Royal Artillery, to Eleanor, eldest daughter of H. Burnard, Esq.
WELCH-SLATER.—On April 10, at St. James's, Clapton, Charles H. Welch, L.F.P.S. Glas., of Cambray-villa, Clapton, to Ellen F. Slater, only child of the late Isaac Slater of the Cape of Good Hope.
LAWSON-BROOKS.—On the 3rd inst., at Blackpool, Wm. Lawson, Surgeon, of Brierfield, near Burnley, to Anne, daughter of J. Brooks, Esq.
COOMBS-FRANKLIN.—On the 4th inst., at Coventry, Carey Pearce Coombs, M.B., of Beckinton, Somersetshire, to Mary Leslie, daughter of W. Franklin, Esq.

SCOTLAND.

DUNCAN-THOMSON.—On April 4, at Mains Tillicoultry, John Duncan, M.D., of Edinburgh, to Jenima, daughter of Alex. Thomson, Esq.

ERRATUM.—In your issue of the 4th inst., which details the proceedings of the last Surgical Society meeting, contains a typical error in the report of one of the cases which I had the honour to bring before that meeting. The words "now malignant," should have appeared *non-malignant*.

HOUSE OF INDUSTRY HOSPITALS,
NORTH BRUNSWICK-STREET.

INTRODUCTORY LECTURE IN THE THEATRE OF THE
RICHMOND HOSPITAL.

By Sir DOMINIC J. CORRIGAN, Bart.,

PHYSICIAN-IN-ORDINARY TO THE QUEEN, CONSULTING PHYSICIAN TO THE
HOSPITALS, ETC. ETC.

SUMMER SESSION, 1866.

GENTLEMEN,—The course of lectures and clinical instructions we inaugurate this day, appears to me to be one of the most important and useful movements in hospital teaching that have occurred in the Dublin School of Clinical Medicine for many years.

I return my best and warmest thanks to my kind colleagues, the Physicians and Surgeons of these great hospitals, for the very great compliment they have paid me, not only in permitting me, but in asking me to inaugurate this movement.

The resignation of my appointment as Physician would have entailed my separation professionally from this great institution and from them, which I should have greatly regretted; but they, in their kindness, forwarded to the Board of Governors, and through it to the Lord Lieutenant, their unanimous desire that the distinction of Consulting Physician should be conferred upon me, to which representation His Excellency Lord Wodehouse was pleased to accede.

I should not express my feelings were I not to take this opportunity of sincerely thanking them, and of adding that I feel, and shall ever feel, very proud of their approbation, and of their mode of evincing it.

I cannot say I have deserved it, but I accept it as a testimony from them, that during more than twenty years of my connexion with those hospitals I have laboured to merit it.

And here I may remark, as an observation to my young friends, that cordiality of action and mutual good feeling among the members of the medical staff of an hospital are to be cultivated, not only for their own sakes, but for a higher purpose—the care of the sick poor, so that all may confide in one another in their doubts or difficulties, and seek one another's advice mutually and unreservedly.

It is in a hospital where there is such cordiality cultivated that the poor are best cared for.

The instruction commenced is intended to supply a want which is much felt—viz., the want of opportunities to students attending some of our other hospitals of studying fever and the acute contagious diseases.

Some of the recognized institutions, both in Dublin and elsewhere, are prohibited by their charters or bye-laws from admitting fever or contagious diseases, while others have not the necessary accommodation for their reception.

It is now proposed to open to advanced students from other hospitals the wards of the Hardwicke Fever Hospital during the summer session, where they can see the various forms of fevers and contagious epidemic diseases on a great scale.

The hospital contains 120 beds. Within the past year there were admitted into it 1411 cases, of which there were:

Fever	1163
Small-pox	103
Scarlatina	12
Measles	27

For a moment I may digress here on the subject of small-pox, in the hope that the facts mentioned may induce increasing attention to vaccination. We had 103 cases of small-pox in the past year. Of 71 vaccinated only 3 died, or little more than 2 per cent.; of imperfectly vaccinated 1 died out of 3, or 33 per cent.; while of the non-vaccinated 29 cases, 8 died, being 27 per cent.; or putting it perhaps more fairly, and classing imperfectly vaccinated and not vaccinated together (and indeed imperfectly vaccinated is worse than not vaccinated at all, for the mark hlls apprehension), the result will be this: the deaths in the vaccinated cases were only 2 per cent., while the deaths in the imperfectly and non-vaccinated were 30 per cent.

On the absolute need of your cultivating an acquaintance with the several varieties of fever it ought not to be necessary to dwell; but I know that some pupils pay little attention to this important class of diseases, and they have cause deeply to regret it afterwards, when placed in circumstances where they want the knowledge but cannot acquire it.

Fever in some form or other is never absent from country or town.

In our army, even in our most active campaigns, for every hundred men killed in action or dying of their wounds, ten thousand perish of fever and its cognate diseases.

How is it, then, that our students generally do not give that attention in fever wards that they give in surgical wards? I fear I must attribute it to indolence.

A broken or dislocated limb is recognized generally with little trouble, and with some students their hospital rounds are confined to what they learn without trouble; in fact, walking a surgical hospital is a kind of "sight-seeing."

But it requires long and attentive observation to recognize the shades and phases of fever, where it is not a single limb or joint that is engaged, but all the functions of the living body, and where it becomes necessary to observe and to estimate the amount of disturbance in each, and those disturbances as difficult to describe and as changing as the hues of clouds are, yet in fever are the signs of recovery or death.

You can learn all these phases and changes if you stay quietly and silently in the fever wards for hours learning for yourself, but you must teach yourself by studious and patient observation; you cannot learn what you want from others or from description, your own eye must be, and can alone be, your instructor.

In no branch of medical studies is the trite quotation more true than in the study of fevers—

"Sægnis irritant demissa per aurem,
Quam quæ subjecta sunt oculis fidelibus et quæ
Ipse sibi tradit spectator."

Let me suppose you now at the bedside of a fever case; stand there quietly, don't disturb the patient, don't at once proceed to examine pulse, or chest, or abdomen, or to put questions. If you do, you may be greatly deceived, for under a sharp or abrupt question a patient may suddenly arouse himself in reply, answer your questions collectedly, and yet die within three hours.

Look at your patient as he lies when you enter the ward or sick-room; his very posture speaks a language understood by the experienced eye.

It is not unusual for the anxious and young resident to draw the earliest attention of the physician in his morning round to some patient who had appeared to him to be in a most dangerous state all night, and for the physician to take a single glance at the patient, and say in reply, "Never mind him, he is all right, come" to the next case, it is a very bad one." What is the difference between the two? Merely that of posture. The first, or apparently very bad case, had gone through the agitation of crisis during the night, but at morning visit was asleep, lying three-quarters on his side, or half on his face, in the posture instinctively chosen to relieve the diaphragm from abdominal pressure, and with

muscular strength enough to retain that posture; while beside him lies the serious case, the man who gave no disturbance during the night, who did not complain, but lies on his back without the preservative instinct and without the strength to change it, and with the abdominal viscera like a nightmare on the diaphragm.

Go next in your study to brain and nervous system. Again, you need not question, and you have wakefulness, eye, and tongue to guide you.

Of all the changes we have to dread, that arising from want of sleep is one of those most to be feared.

Never forget that a patient in fever may die from want of sleep, and want of sleep alone, without one single organic lesion. Sleep is the rest of the brain, as repose is the rest of the limbs.

The brain can no more continue to work without sleeping, which is its rest, than the muscles of our limbs can continue to act without repose, which is their rest.

A man will die from fatigue of his muscles without other disease, just as the hunted hare dies; so will man die from fatigue of his brain without organic disease, and whenever a patient passes a day and night without sleep, though all other symptoms seem favourable, look out for danger.

The eye of a fever patient will tell you much. The appearance of the pink sclerotic that indicates acute congestion in the vessels of the head, and the livid red of the conjunctiva in typhus that indicates passive congestion or atony of the capillary system, are very much alike in appearance, and easily mistaken for one another; but seen and recognized and painted on the tablet of your memory, will never be forgotten. In the child in fever there is another sign revealed to you from merely looking at the countenance, and always to be dreaded—it is frowning, however slight. A frown is not natural to a child, and it is often the first sign of commencing mischief in the child's brain. Wakefulness, headache, and frown are of more serious import in the child in fever than in the adult.

There is an apparently trivial sign about the eye of a fever patient, which you will lose if you rudely disturb the patient or question him. It is the passage of the tear. If the secretion of the lachrymal gland flow in its natural course, and pass out through the nasal duct, having performed its office of washing the eyeball and keeping it moist, it is a good sign, for it indicates that the instinctive functions of organic life are still performed; but if the eyelids cease to act, and that the tear-drop falls over the outer angle of the eye, it is a sign that the functions of organic life are beginning to give way.

The cheek alone will tell you much; and the red patch on each cheek, eminently characteristic of typhoid fever, or "follicular enteritis," without a question tells the experienced eye that the case before it is not typhus.

There still remains one other remarkable sign speaking to the eye, the pulsation of the carotids. These vessels may throb either from increased impetus from the heart, or from increased rapidity of circulation with debility.

Here, for the first time, the eye is at fault, and we must bring in the assistant sense—touch. Small-pox illustrates what I mean. During the progress of the pustular stage, for about eight days from its commencement, or eleven from the commencement of premonitory fever, there are the usual febrile symptoms, but about the eighth day of the eruption, when the pustules are fully matured, the patient often becomes delirious; the pulse is more frequent, the circulation is carried round in its circle with increased rapidity, and every artery in the body throbs. The carotids seem to throb violently, but lay your finger on them, and you find they bear little or no pressure, and that what seemed a pulsation of violent force is the appearance produced at each filling of the vessel as contrasted with its immediately comparatively empty state. It may be likened to the rush of fluid without force along a tube previously flaccid. It is scarcely necessary to add that these appearances in the carotids, so like in their resemblance, so different in their nature,

indicate very opposite lines of treatment, and a mistake may involve the loss of life.

Again, the eye will distinguish between cerebral breathing and pulmonic oppression.

You can now form an idea of how much may be learned from the mere inspection of a case of fever without asking the patient a question, and I think you will agree with me that you learn much from eye and touch alone; but again I must impress on you that you must learn all this for yourself, and that the study you are now entering on in many particulars requires more patience, more attention to niceties, more cultivated observation than your previous studies.

In reference to the examination of the system of circulation, on the sustainment of which so much depends in the treatment of fever, I would impress on you in judging of the strength of the heart's actions, to depend on the pulse, radial or carotid, not on the examination of the heart's sounds or impulse by the stethoscope.

I think you will not impute to me any, even the faintest, desire to disparage the stethoscope, but when information is wanted, always choose that way which is surest and safest.

When it is desired to ascertain the force with which a gun propels its shot, the power is not estimated by the noise of the explosion or the force of the recoil. The force with which the shot is impelled and the distance it reaches are the tests of the power of the gun.

The heart is the gun which at each contraction discharges into the aorta a cylinder of blood of about one inch long, which propels before it the blood already in the aorta and branch arteries, and the force with which that cylinder propels before it the blood in the arterial tube and strikes your finger in radial or carotid pulse, is the best and surest measure of the force of the heart's action, just as the force with which the cylindrical shot strikes the target is the best and surest test of the force of the gun. But even could the stethoscope give as accurate information as the pulse, I would still counsel you to rely on the pulse, for which you are all practised daily and continuously in educating your sense of touch, while you never can become as accomplished in judging of the sounds of the heart.

There are other causes of fallacy in relying on the stethoscope. The heart may lie close to the ribs, as it nearly always does in the female and often in the male, and then both sounds and impulse will be sharp, even with a heart of weak but irritable muscle, while in a strong man, with a large round chest and strongly acting heart, so thick a layer of lung may intervene between heart and rib that the layer of lung will act like padding to deaden sound, and like a buffer to intercept impulse.

Again, suppose you come to the conclusion that pulse and stethoscope contradicted each other, which would you trust?

The pulse indicated antiphlogistics, antimony, and depletion, while the stethoscope indicated, as you supposed, feebleness of heart's action and stimulants, which indication would you rely upon?

I think you will answer with me—Trust to the pulse in preference to relying on the stethoscope.

There is another portion of the great circulating system which you can examine with the eye—the great capillary system.

The preservation of this great part of the function of circulation is of vital importance in the treatment of fever, and hence the use of flying blisters, sinapisms, external heat, pure air, &c. &c., by which we hope to stimulate and sustain it.

You will not fail to recognize the great importance of attending to it, when you recollect what comparative anatomy and physiology teach us, that the capillary circulation is the fundamental circulation of life; that large vessels are added as animals ascend in the scale; that even in fishes the great function of circulation through the system is carried on without a heart, and that the heart is but a supplemental organ in the upper classes of animals

to propel a supply for the capillaries, as the donkey engine lifts the great water supply for the main machinery.

If it were possible to make a selection, it would be more important in fever to maintain the function of circulation in the capillary system than in the heart; but in the upper classes of animal life, and especially in man, so intimate are these relations that if one fail so must the other soon succumb.

Both or either may fail from over-loading or congestion, or, on the other hand, from feebleness, and on this difference often depends what is called the type of fever; that is, whether its form is such as that, by antiphlogistic treatment, by simply relieving the vessels, they can return to their former state, like elastic tubes that have not lost their resiliency; or whether, even if their distended state be relieved, they then require a stimulant treatment to excite them to action; or, following the illustration of the elastic tubes, they require stimulation to restore them, resembling elastic tubes that have lost their resiliency.

The colour of the macule on the skin guides us as to the state of the capillary circulation.

We know that in experiments on the capillary circulation the first change of colour is from the blood moving slower and slower, and in the same proportion becoming darker and darker, until at last its movements cease altogether, its colour is black, and life in the bunch of capillaries has ceased.

We see this change going on in the macule of typhus fever. Dots of dusky red to-day become darker to-morrow, and in one or two days after nearly black, and whenever, as in lying on hip or back, there is the additional impediment of pressure to circulation, the capillary circulation ceases, and gangrene or death of the part is the result.

Proceeding with the examination you now pass to the abdominal viscera, which claim your attention, not only on their own importance, but as their state may seriously interfere with the respiratory movements of the lungs, either by their weight and mass pressing against the diaphragm, or by their distension interfering with its descent among the organs within the abdomen. There is one, the bladder, which preëminently should ever have your continuous and unremitting attention.

Trust to no one's report of its state, not even the patient's own.

It will distend to great size, containing often two quarts of fluid, putrefying or throwing back its poisonous urea into the system, and all the time, perhaps for several days, the overplus passing away leads the careless or the ignorant to suppose that the bladder has emptied itself; and, paradoxical as it may appear, the most accomplished and most attentive surgical intern is even more likely than another to overlook the state of bladder.

He has been accustomed to relieve the bladder of its contents most often when a mechanical obstruction has existed for some short time, when the bladder still maintains its muscular power, or when the obstruction being complete, the bladder is distended tensely, like a globe in shape, and is visible as such even to the eye and felt as such under the hand.

This is not its state in fever. The obstruction is not complete; while the fluid is dripping into the fundus, it is leaking out at the neck through the urethra, while a portion continues to accumulate behind in the passive bladder, which makes no ball-like protuberance, but lies as a passive flattened bag among the intestines.

It offers no resistance, but recedes on pressure, and in this state it may be productive of much mischief, of convulsions or death.

The contained urine passes into putrefactive fermentation with great rapidity.

In twenty-four hours it becomes intolerably ammoniacal and fetid.

There are only two ways of detecting this state, by percussion and by the catheter. A very little practice is sufficient by percussion to determine whether there is water

in the bladder; but if at all in doubt, use the catheter. Its introduction gives neither pain nor annoyance.

I did not intend to make any observation whatever on treatment, but I have made this exception, having too often seen the neglect I have noticed occur, and its sad consequences.

I shall conclude with a few observations on a question that has created considerable attention—viz., whether typhus fever and typhoid fever are merely modifications of one another, or whether they are different diseases. Judge for yourselves, you will have abundant opportunities; you will see them in the Hardwicke lie side by side; compare them at the same moment and watch their progress from day to day, and I think you will come to the same conclusion at which I have arrived, after an observation of many years, that they are distinct and separate diseases.

I would not spend your time or mine on the question if it were merely theoretical, but it is essentially practical, seriously affecting treatment, and the use of two of our most important therapeutic agents, opium and stimulants; for while, in many cases of typhoid fever, we can keep the patient with great advantage under the mild and continued influence of opiates, we must be very wary indeed, as to their use in typhus, and while we may use stimulants very freely in typhus, we must often be very chary of their administration in typhoid fever.

It is to be regretted that the name "typhoid fever" has ever been used, for the very name typhoid gives a bias to the mind to think that typhoid is a variety of typhus, just as typhoid applied to erysipelas and scarlatina mean a low type of those diseases.

Another name has been lately introduced, "pythogenic fever," which presents this objection, that the name is founded on a supposition as to the cause, not the nature, of the disease. I think it is hard to contemplate even in mere aspect the two diseases and consider them as one, so strongly do the bright pink-patched cheek, fissured tongue, and lenticular prominent eruption of typhoid fever contrast with the livid countenance, brown tongue, and dark macule of typhus. It would take us too long to go at length into the diagnostic symptoms.

One of the reasons advanced by some who look upon them as varieties of the same disease, is that they have the same origin, arise from the same poison, either of contagion or malaria; but surely, although the poison and sting of a hornet may give rise to pyæmia, erysipelas, anthrax, or gangrene, no one could argue that all those diseases are the same because they owe their origin to the same poison.

Another argument to the like effect has been drawn from typhus spots or macule, occasionally making their appearance in the course of typhoid fever. Typhus spots or macule are simply congestions of bunches of capillaries, with or without effusion of blood under the cutis, but these macule or typhus spots may appear, and often do appear, in scarlatina or measles, and surely no one would argue from the combination that macule and measles, or purpura and scarlatina, are the one disease.

The real practical point for your consideration is, not whether they owe their origin to the same or similar causes, but whether the principles that guide treatment in typhus fever should guide it in typhoid, or *vice versa*—judge for yourselves. I believe you will come to this conclusion, that for all practical purposes you must consider them different.

It now only remains to thank you for your attention to an introductory lecture, that I have not attempted to make either deep or learned, but to consist only of those modes of thoughts and observations that I found useful to myself in studying fever, and which I trust may, perhaps, be not always fruitless to you, and while I again thank my kind and esteemed colleagues for their kindness, I have a favour to ask which I know they will grant, that while they have done me the honour to name me "Consultant," they will allow me to be a "perpetual pupil," and still come to these wards to learn, though not to teach.

THREE CASES OF DISTORTION OF HAND.

By RICHARD BARWELL, F.R.C.S.,

ASSISTANT-SURGEON, CHARGING-CROSS HOSPITAL.

In June, 1865, was brought to my notice a child aged 6, the fingers of whose left hand were webbed—viz., the index, middle and ring fingers were united.

Previous to coming under notice two operations had been performed on the hand with the knife, an attempt also had been made to establish separation of the fingers with the seton; both these had failed, but the parents were still anxious that the hand should be, if possible, restored.

On examining the fingers I found them connected together, not merely by a thin web, but by a thick layer of tissue covered in front and back by skin from corresponding parts of the fingers; or, in other words, the three outer fingers appeared as one broad mass, marked before and behind by two shallow grooves indicating the normal but absent separation. There were marks of old scars at different parts of these grooves, and a separation existed between the last phalanges of middle and ring fingers to nearly half their extent—the persistence of movable joints was in some parts doubtful, as between the first and second phalanges of the index, and all the joints were certainly stiff from want of use.

In considering the conditions of this case, the thickness and fleshiness of the bonds between the fingers, the three previous futile attempts at producing permanent separation, it appeared to me useless to try any other means than implanting a fresh piece of skin into the wounds left by cutting the fingers asunder. The next point was the place whence the fresh skin should be taken, and I chose the buttock behind the great trochanter, because a scar in that situation is seldom visible.

On the 22nd July, chloroform having been administered I thrust a straight bistoury in a sloping direction from behind forwards through the tissues, uniting the index and middle fingers, keeping the blade much closer to the latter, so that, when the whole length of the digits had been separated, so much tissue was left on the forefinger that its edges could be brought neatly together and sewn with wire. The same proceeding was then used at the next interspace, the greater amount of skin being left and sewn round the inner side of the middle finger. Thus the wounds to be filled up lay on the outer side of both middle and ring fingers and at the fork, or point of their bifurcation. Of these wounds an impress was taken on a piece of paper and the necessary pieces were cut from the haunch in such wise as to leave a portion of skin between the two excavations and also so as to enable me to lift up each strip-like piece in a loop while it remained attached at either end. The wound in the buttock was closed with silver wire, the fingers to be covered were thrust through their respective loops, and first the palmar edge was stitched—a process which required much care and ingenuity—then the dorsal aspect was secured, and afterwards the hand and arm were carefully bound *in situ*.

The child slept well during the first two nights, on the third pain kept her restless, and on the fourth day—viz., on the 25th July—I removed the bandage and cut away the skin connexions with the haunch. The hand had swollen from position, but only a very small part of the implanted skin had died, the rest was fairly united. It is unnecessary to follow the details of the case farther; it did uninterruptedly well, and in a month the hand was healed, passive motion had begun to render the fingers more mobile.

Case 2.—This girl's eldest sister, aged 13, had a small cartilaginous tumour developed in one of the flexor tendons of the ring finger; the case was interesting to me, as showing the amount of muscular contraction necessary to produce movement of limb. Thus when the fingers were straight and the wrist fully extended, the tumour lay under the annular ligament of the wrist, the distance between it and the internal condyle measured $8\frac{1}{2}$ inches, when the fingers and

wrist were flexed to their full, the tumour moved up the arm and became placed at the distance of $6\frac{1}{2}$ inches from the inner condyle; thus the muscular structure to which the swelling was affixed contracted if it were fixed to the superficial flexor very nearly a quarter of its length.

I removed the tumour with the knife of course, without dividing the tendon, and found it to be imbedded among the fibres of the deep flexor tendon of the ring finger, and therefore the proportion of muscular contraction must have been much higher.

The piece of cartilage was the shape of and about as large as a horse bean. The wound healed quickly; although a little synovial oozing continued for eight days, there was no suppuration, and the case did perfectly well.

Case 3.—Miss L., aged 19, was brought to me by her parents, October 4, 1865, with the middle finger of the right hand bent down and doubled into the palm—a source of such inconvenience that the hand became nearly useless. The origin of the affection was a fall three and a half years ago, in which the hand and wrist appear to have been doubled up under the body. Great pain and some considerable swelling were produced, the whole hand remained lame for some months, and when it became capable of use, the middle finger, even then much bent, curled up more and more into the palm. She has sought surgical advice and has been greatly persuaded to allow the tendons to be divided.

I found the middle finger strongly retracted, the first phalanx bent down forcibly, and each one flexed on its neighbour. By the exercise of some force it could be slightly brought out of the palm, giving to the hand of the surgeon the sensation of stretching a spring. As soon as the finger was released it flew back again. The movements of the ring and little fingers were constrained and awkward, but this seemed rather owing to the position of the middle finger than to any inherent defect. The patient's health being perfect, there remained for consideration only the form of operation to be adopted, and this alone is a subject presenting difficulties sufficiently grave; but which are in this sort of case neither duly studied nor recognized. Indeed, operations for the cure of distorted and stiffened joints are, as a rule, described as though after cutting tendons, &c., the limb, being easily placed in position, rapidly regains its mobility and power. Such, however, is never the case; the true restoration of a joint is difficult and protracted, according to the amount and duration of fixity and distortion. The division of tendons or muscles in some joints certainly does facilitate restoration of posture. In other parts it does not even effect this object, while it frequently protracts recovery of function, and in some parts of the body renders such recovery impossible. This is especially the case with the fingers. The method in which the superficial and deep flexors are bound into their sheaths, the peculiar attachments of the interossei, and the false bands from the palmar fascia, as well as ligamentous contracture, all combine in enforcing the abnormal posture. Thus the section of one or both flexors in the palm has very slight influence on our power of straightening a crooked finger, but has vast influence in rendering the subsequent mobility of the limb very slight indeed. After such section, the second and last phalanx, one or both, are frequently incapable of voluntary flexion, and even if they can bend, their movements are confused and difficult.* The anatomical conditions properly understood fully account for such a result; but I would here refer especially to the foregoing case, which shows that if a tendon of a retracted flexor muscle be cut and the fingers straightened, the divided ends will lie two inches asunder, and thus even if the tendon unite, the union cannot possibly be isolated; its action must, therefore, be confused and chaotic. For these reasons I refused to sanction any division of tendons until, at all events, every other means had been tried. I

* See account of a commission on a case of M. Guérin.—*Bulletin de l'Académie de Médecine* (viii).

proposed stretching the parts under chloroform, once certainly, perhaps twice, or even three times, cautioning the parents that after-treatment would occupy a considerable time, and that power of perfect extension could not be ensured. In spite of this not very favourable prognosis, my proposal was after a time accepted, and on 6th November chloroform was very fully exhibited, and I proceeded to straighten the finger. It yielded at first pretty readily, but after a time the utmost limit of what the unassisted hand could do was reached. I had, however, provided myself with a wooden lever, ten inches long, the middle part of which was hollowed so as to fit with sufficient accuracy the back of the finger. While the first and second phalanx and the wrist were flexed to their full, the third phalanx could be with tolerable ease straightened on the second. These two were bound tightly by a narrow band (half-inch broad), and with many involutions to the lever; then with great caution, but also with a certain vigour, the second phalanx was straightened on the first, and the first, as nearly as seemed prudent, on the metacarpal bone. Then while these parts were held in place, the wrist was straightened, the splint was bound to the hand. The patient soon after recovery from the anaesthesia complained of pain. I waited as long as it was endurable, then removed the wood and applied in its place a splint, which kept the finger semi-flexed. Application of cold was ordered to the hand, wrist, and forearm; half a grain of morphia with ammonia was ordered to be repeated in four hours, if necessary.

On the fourth day the splint was removed, the swelling had all but disappeared, passive movement was quite endurable, as long as extension was not carried beyond a certain limit; however, by firmness of hand and careful management, I day by day got the finger straighter. I wished to employ some force which would keep up extension without acting as a rigid band. Several methods of applying steel springs completely failed, either from their twisting round, pressing too violently in places, or other cause. I adopted, therefore, the following plan:—A strip of strong plaster, three-eighths of an inch broad and about a foot long, was split from one end to a little beyond the middle, the two split parts were crossed at the fork, so that the right one became left, and *vice versa*; this portion was then laid upon the pulp of the finger, the unsplit strip was carried over the end and nail, and made adherent to the back of the phalanx; the split parts were then wound round and round until the whole phalanx was covered, the unsplit piece of plaster projecting on the back to the middle of the hand. A similar mechanism was adapted to the second and first phalanges. Thus to each inter-node of the finger was attached a strip of plaster after the manner of an extensor tendon, and to each could be attached an elastic force springing from the forearm after a method fully described elsewhere.* By these means a variable degree of extension, without rendering the finger immobile, could be maintained, and the limb could be extended by manual force, without undoing the dressing. In six weeks the finger, considerably straighter, did not further improve; it was therefore determined again to give chloroform, and this time, during insensibility, attention was expressly directed to the fascial and subcutaneous bands. However, the straightening was accomplished with greater ease than the last time, and a further effect produced. The same plan of after-treatment was carried on. In another six weeks the finger appeared in the usual position of the hand normal—that is to say, in all posture in which the fingers are slightly flexed; but the second could not be quite straightened on the first phalanx nor the latter on the metacarpal bone. With this exception, the functions of the part were perfect; lateral movement and flexion quite free.

Under these circumstances, and seeing that the want of extension was so slight as no longer to be considered a deformity, that the hand was again useful for needlework and the piano, I recommended the patient to be, at all events

for the present, content with the result, and simply to prevent any tendency to return by straightening the finger frequently with the other hand and wearing a splint at night. There is at present date no tendency to relapse.

Hospital Reports.

[THE following reports are particularly worthy of notice. I am indebted to Mr. Hamilton, not only for the kindness with which he showed me the cases hereafter referred to, but also for his correction and revision of the report. To Dr. Lyons I am also indebted for affording me every facility for insuring the due publication of his cases, and for the use of his private notes which he kindly handed to me for the purpose. Some important reports from the Meath and Mater Misericordiae Hospitals are unavoidably deferred to our next issue.—T. W. B.]

RICHMOND HOSPITAL.

THREE CASES OF CHRONIC ABSCESS.

(Under the care of Mr. HAMILTON.)

THESE cases exemplify the different methods advantageously used in the treatment of these abscesses according to the peculiar nature of each. Such abscesses are frequently mistaken for other surgical affections, chiefly tumours, of which the second is an interesting example. The relation of a well-authenticated case of the kind is of considerable practical importance to the surgeon.

E. G., æt. 29, was admitted to the Richmond Hospital on the 10th January, 1866. She stated that in June previous she received a hurt from a door on the crest of the right ilium, but until the following September she did not experience any pain. At that time she felt a dragging pain in her back, and this continued until about six weeks before her admission to hospital, when she remarked a small lump on her side (on the crest of the ilium); this gradually increased until it attained its present size.

On admission, she complained of great pain in the back and right side, and was unable to lie on her back. The abscess was very large and diffused, extending over the ilium from the crest to the sacrum; fluctuation was very distinct, and there was no discoloration of the integuments. The matter was covered by the *glutæus maximus*. On the 15th of January, after some preliminary treatment, Mr. Hamilton opened the abscess and inserted one of Chassaignac's drainage tubes.

A good deal of thin greenish matter, with yellow curdy and flaky material through it, was given exit to. This was followed by much relief. At four o'clock the same evening she had a rigor, and the abscess was painful.

17th: Thin fetid discharge very profuse, coming out by the sides of the tubes and not through them. The tubes merely acting as setons to keep the openings from closing.

21st: Became affected with pleuritis of the left side of the chest with bronchitis, which yielded to treatment, and towards the end of the month she had recovered from both, but she was greatly cut up by the illness, and still more by the profuse discharge and night perspirations, want of appetite and of sleep, with pain and great tenderness in the abscess. Mr. Hamilton removed the drainage tube, and on the 30th January he made a large opening in the centre of the abscess, giving exit to much fetid pus and air. From this she continued rapidly to improve in health and strength.

On the 5th of February there was no pain and no matter discharged from the abscess, and on the 12th it was quite healed.

Case 2.—B. P., æt. 27, a stout healthy-looking country-woman, unmarried, was admitted into No. 10 ward on the

* "Cure of Clubfoot," &c.

26th of February, 1866. She states that about three and a half years ago a small tumour appeared near her shoulder; and that it gradually increased in size until her admission. She further stated that the tumour had grown more rapidly during the last six months than before that time; that she got no hurt, so far as she knows; and that she never felt any pain in the part.

She had been in the habit of blistering and poulticing it, and she observed that the poulticing increased its size.

The following were the most prominent symptoms on admission:—

There was a tumour about the size of a small melon, round, and with a well-defined margin, situated below the clavicle, and lying in the depression between the great pectoral and deltoid muscles, it was quite movable and unattached save at the inner edge of the deltoid, in some of the fibres of which the cyst appeared to be entangled. The integument covering it was colourless, and there was a distinct sense of fluctuation imparted to the touch all over the tumour. The cyst appeared to be very thick and dense, but was thinner in some places than in others.

The diagnosis was the practical point in this case; and that it was difficult may be inferred from the fact that it had been sent into hospital as one of encysted tumour, which it had been pronounced to be by some surgeons of good authority.

Mr. Hamilton, on careful examination, doubted it was so, and arrived at the conclusion that the case was one of chronic abscess. Seeing, however, that there was some difference of opinion about it, he determined to make an exploratory puncture, and accordingly on the 7th of March the patient was brought to the operating theatre. He made a puncture with a bistoury, and on its withdrawal there followed a gush of rather thick and very yellow pus. Two days after the patient complained of slight headache and shivering, but this soon passed off, and the wound healed.

12th March: It appeared as if the sac was filling up again, and it was rather tender. On the 17th the strong tincture of iodine was ordered to be applied over it. A week after it was noted that "under the application of the tincture of iodine, the tumour appears to be gradually growing less." I saw it on the 11th of April in company with Mr. Hamilton, who showed its position, but it had then become so small that it was not very clearly to be made out. A few days after, the girl, wishing to go home, and as Mr. Hamilton considered there was still some fluid in the remains of the abscess, which, were there time, would be absorbed, he thought, under the circumstances, that it was best to let it out before she left the hospital. He accordingly made a small puncture with a lancet and a small quantity of thin pellucid fluid came out. Next day there was no sign of the tumour and she went out.

Case 3.—Edmond Murphy, aged 12 years, was admitted into the Richmond Hospital on the 7th of March, under the care of Mr. Hamilton, for a chronic abscess situated over the seventh and eighth ribs on the left side.

The history of his case is as follows:—

About two months ago, while at play with other boys, he received a blow of a policeman's hat (made of very strong material to afford protection to the wearer) on his left side. From the date of the receipt of the blow he suffered occasionally from pain in his side until a fortnight before his admission into hospital, when the tumour on his side appeared.

The patient is a delicate-looking boy, having a scrofulous diathesis, marked by the fairness and transparency of his skin, by his light grey eyes, and by his neck being covered with the cicatrices of numerous scrofulous ulcers. The boy states that he occasionally has night-sweats; otherwise, his general health appears good.

On examination Mr. Hamilton found a chronic abscess about the size of a half orange, having its long diameter parallel to the axes of the ribs, lying on the eighth rib, and most probably connected with caries of this bone; fluctuation distinct, and the tumour, as it were, bound

down to the rib, so intimate is the connexion between them.

A week after patient's admission an eschar was made over the tumour with potassa fusa; a few days later the slough separated and a copious discharge of greenish yellow matter containing a few shreds of lymph took place. The discharge continued for some time, and finally the cavity having closed up, the boy was discharged cured on April 5th. In this case the opening of the abscess was not followed by the slightest constitutional disturbance, indeed the boy appears to have put up flesh on the hospital regimen.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

DR. LYONS'S CLINIQUE.

PHANTOM TUMOUR OF THE ABDOMEN.

A. B., aged about 20, a florid and healthy-looking girl, of sanguineous temperament, unmarried, was admitted into the Whitworth Hospital, labouring under a combination of muscular and arthritic rheumatism. Menstruation was regular, and, under the influence of appropriate treatment, the rheumatic affections were very sensibly improved in all parts except in the muscles of the upper extremities and the shoulders, elbows, wrists, and small joints of the hands. On the slightest attempt at either voluntary or forced motion of any part of either upper extremity, extreme pain in the corresponding joint was complained of, and the patient lay in bed, unable, or unwilling, to assist herself in the most simple and ordinary offices of life. This condition persisted after all trace of pyrexial action had subsided; and, with a clean tongue, cool skin, and quiet pulse, the statements made as to the inability to perform or support ordinary movements of the upper extremities without exquisite pain seemed not a little apocryphal. It may be mentioned, in illustration of any presumed moral obliquity on the part of the patient to simulate sufferings which she did not really experience, that example was abundantly supplied by the undoubtedly feigned performances of a hysterical pseudo-epileptic for a considerable period an inmate of the same ward. Before the subsidence of the acute symptoms in this case, attention was attracted to the presence (unconsciously to the patient) of a considerable tumefaction of oval form, somewhat tender on pressure, very firm to the feel, in the situation, and apparently somewhat of the dimensions of the gravid uterus at about the fifth or sixth month, and in no small degree simulating the characters of such a tumour, save that it was distinctly bifid at the upper extremity. The circulatory system was at this period singularly excitable; the face flushed up at the least emotion, and the pulse rose to 120 or 130 under the most trivial influence. The rapid action of the aorta heard in the supposed tumour, under these circumstances, might have been, by a hasty or superficial observer, confounded with the action of a fœtal heart, and would have materially strengthened the supposition, had such been entertained, that the patient was advanced in pregnancy. The absence of mammary enlargement and of discoloration of the areolæ, the alleged menstruation of very recent occurrence, the bifid character of the superior extremity of the tumefaction, and, above all, the clearness of sound elicited on percussion, plainly pointed to a condition not that of pregnancy; and, on very careful exploration, it was ascertained that the swelling was due to a rigid and somewhat tumefied state of the inferior divisions of the recti abdominis muscles. This opinion was in a day or two subsequently found to be still further borne out by the occurrence of a precisely similar state of rigidity and tumefaction of the superior divisions of the same muscles, well-defined in the mesial line by a deep sulcus, into which the fingers sank, corresponding to the linea alba, and externally by the linea semilunaris on either side. Under the use of bromide of ammonium and bark, with daily

Electric shocks through the upper extremities, strictly low diet, and the combination of decided, though gentle means of moral suasion, this patient has daily improved, and is now able to sit up. The tumefaction of the recti has subsided, and the phenomena of a tumour have disappeared.

The case is worthy of record as another example of a possible source of error in the exploration of abdominal disease.

Pneumonia—Tonic Treatment—Recovery.—The following case may be very briefly noticed, as an example of the successful employment of the tonic plan of treatment in a case of extensive inflammation of the right lung:—

J. M., aged 33, of slight frame and delicate, if not cachectic aspect, a cutler's helper, was found on admission to be suffering from very extensive pneumonic consolidation of the entire posterior half of the right lung, with concomitant bronchitis in both lungs. The general debility of the patient, the feebleness of the circulation, and his somewhat cachectic aspect, seemed clearly to contraindicate the use of either mercury or antimony. He was at once placed on five-grain doses of sulphate of quinine, with beef-tea, milk, and four ounces of wine.

On the third day after admission the pulse had fallen to 92; respiration was becoming much freer; crepitus *redux* was extensively audible, and expectoration was copious. The quinine was continued as before, his wine was increased to six ounces, and nourishment as previously ordered, with the addition of an egg daily.

On the three following days the pulse fell successively to 68, 64, 60, and in all respects amendment was rapid and permanent, as evidenced by clearing up of the lung, and returning appetite and strength. Slight acceleration of the pulse took place a day or two subsequently, but without arrest of the general improvement in the patient's condition, who was soon able to sit up and walk about the grounds; and having infringed the rules of the institution and left the hospital for some hours, on the twelfth day after admission, it was not deemed necessary to re-admit him, nor was there anything in his state or symptoms to call for it.

This case presented in many points a very unpromising aspect at the outset, and Dr. Lyons feels convinced that under any lowering plan of treatment, such as general abstraction of blood, mercurialization, or the employment of nauseating doses of tartarized antimony, the result would have been different. The patient took in all about 240 grains of sulphate of quinine in nine days, and about 68 ounces of wine. As it was, defervescence took place with very unusual rapidity, resolution of the lung, *pure et simple*, must be assumed to have been accomplished, and that rapidly, as there was a total absence of purulent expectoration, and convalescence was established within a very brief period.

Old and renewed Tuberculization of Lung—Advanced Renal Degeneration—Dropsy—Death—Remarkable condition of parts of the Brain—Gangrene of the Brain.—The patient, a female, aged 20, unmarried, was admitted into hospital in an advanced stage of phthisis with general anasarca and effusion into the abdomen. Cough was frequent and distressing, and there was constant and copious expectoration of purulent and offensive sputa. The urine was albuminous and of sp. gr. 1016. This unfortunate sufferer showed an extraordinary tenacity of life, and notwithstanding her distressing cough, dyspnoea, occasional nausea and vomiting, frequent diarrhoea, the irritation of bed-sores, and extreme prostration, she lingered on for a very protracted period. For two or three days previous to death she lay apparently but little conscious of what was going on around her, occasionally moaning and crying out in pain and distress, but no symptom indicative of special cerebral lesion was at any time observable.

On post-mortem examination, the left lung exhibited at the apex, two or three well-marked puckered cicatrices, the unmistakable evidence of old tubercular

lesion. Several vomicae of recent date, and still containing purulent fluid, but of no considerable size, were found throughout this lung; the right lung was in a state of engorgement, and supplementary emphysematous distension. The kidneys presented well-defined evidence of advanced fatty degeneration.

On removing the brain the arachnoid was found studded with deposits of lymph in numerous situations in both hemispheres, and in the subarachnoid spaces there was considerable effusion of yellowish and somewhat grumous serum. The lateral ventricles contained a very considerable amount of the same grumous serum, mixed with small yellowish lymph flocculi. The colour and appearance of the corpora striata at once arrested attention when the ventricles were opened; the left presented a decided olive green tint, and the vessels on its surface were of a dark hue; the right corpus striatum exhibited a similar appearance, but the colour was less dark. On section being carried through the left corpus striatum, the green tinge was found to extend about one-quarter inch through its substance; the optic thalamus and the fibres which pass upwards through both these bodies from the crus cerebri were in a state of perfect integrity, and the morbid condition was rigidly limited at the junction of the thalamus opticus and corpus striatum.

The under portion but not the surface layer of the anterior and part of the middle lobe of the right hemisphere was in a condition very similar to that of the corpus striatum; the colour, however, being rather a greenish yellow than dark, the skin green, which characterised the affected portion of the left corpus striatum.

On microscopic examination the cerebral substance presented evidence of much disorganization; the nerve cells and tubes were broken down, and only here and there recognizable; much granular and molecular matter filled the field, but there was an absence of corpuscles of compound granular growth, pus corpuscles, or other definite elements indicative of vital metamorphosis. Vessels blocked with blood corpuscles were here and there observable; and on the whole the condition seemed to be the result of excessive disintegration, with no effort at repair, and was so far analogous to the state of sphaeculating tissues. The vessels in the Sylvian fissure, as well as those of smaller size in the choroid plexuses, and those crossing between the thalami and the corpora striata, as well as upon the latter, were carefully examined, but without any embolic or other obstruction being detected. This morbid condition, in all probability, occurred but a few days before death, and during the period when the patient lay in a state of insensibility, occasionally giving utterance to moans and cries. Neither its exact pathological origin nor its significance appears to be definable, but Dr. Lyons regards it as analogous to, if not identical with, the condition of gangrene of the brain substance, alluded to by several writers, but very imperfectly described by all.

PROFESSOR BOECK'S TREATMENT OF SYPHILIS.

MR. HENRY LEE of St. George's Hospital, London, after an elaborate series of experiments, concludes his lectures on this subject with the following axioms:—

1st. That no evidence has hitherto been adduced satisfactory to the profession that the infecting form of syphilis can be inoculated upon a patient who is at the time the subject of constitutional syphilis.

2nd. That both from a soft sore, and also occasionally from the surface of an indurated sore, matter may be taken which may be made to produce a number of local specific ulcerations having the characters of the soft chancre.

3rd. That during the continued irritation of such ulcerations the manifestations of secondary syphilis will disappear.

4th. That the time required for the treatment of syphilis in this way is so long, and the inconveniences attending it are so great, that it is not in any degree likely to be adopted in private practice in England.

Proceedings of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 10TH.

Dr. ALDERSON, F.R.S., President.

NOTES ON THE PATHOLOGY OF PNEUMONIA AND HEPATITIS.

By C. MOREHEAD, M.D., F.R.C.P.,

LATE PRINCIPAL AND PROFESSOR OF MEDICINE AT GRANT MEDICAL COLLEGE, BOMBAY.

I. THE object of this paper is to show that the pathology of inflammation of the lungs and of the liver cannot be rightly understood unless it be kept clearly in view that in both organs there is a double system of capillary circulation; that of the bronchial and hepatic arteries being for the nutrition of tissue, and that of the pulmonary artery and of the portal vein for functional purposes; the one being of arterial blood, and the other of venous blood.

The pathological question in respect to both organs is, which system of capillaries is the seat of inflammation in pneumonia and hepatitis?

II. *Pneumonia*.—It has been lately argued before the Society by Dr. Waters that the branches of the pulmonary artery which constitute the pulmonary plexus are the nutrient vessels of the air-cells and the seat of inflammation in pneumonia, because—1st, capillaries of the bronchial artery do not exist in the air-cells; 2nd, the absence of the bronchial arteries in some animals shows the capability of the pulmonary vessels for the purpose of nutrition.

It is argued in the present paper that if inflammation be an altered state of the nutritive processes of the affected part, then the capillaries immediately concerned in inflammation must necessarily be those which in their normal state circulate arterial blood for purposes of nutrition; that the blood which is a factor in inflammation must always be blood which in the normal state is a factor in nutrition. It is maintained, therefore, that capillaries of the bronchial arteries are those immediately concerned in the nutrition of the air-cells and in pneumonia, because—1st. They are the nutrient vessels of the visceral pleura, of all the tissues of the bronchial tubes, the coats of the bloodvessels, the nerves and lymphatics, and the connecting areolar tissue of the lungs, and the seat of inflammation in visceral pleuritis and bronchitis. 2nd. It is improbable that bronchial capillaries should ever be discoverable in the air-cells, because (*a*) inflammation of the air-cells must always be followed by turgescence of the pulmonary plexus, and (*b*) artificial injection of a bronchial artery always in part fills the pulmonary plexus; hence bronchial capillaries, if existing in the air-cells, are almost certain to be veiled by the larger pulmonary plexus under the only circumstances in which it is reasonable to expect to see them. 3rd. Though admitting, as is very likely, that bronchial capillaries do not exist in the air-cells, it does not follow that the blood of the bronchial arteries is not the nutrient blood of the cells and the factor in inflammation. May not the thin walls of the cells be nourished by a process analogous to that which is effective in the cornea, articular cartilages, and lamellated osseous tissue? The capillaries of the termini of the bronchial tubes and of the interlobular areolar tissue carrying the blood near enough to the air-cells to admit of their nutrition by imbibition of the plasma. 4th. The argument, from analogy, that because there are animals without bronchial arteries, there may be nutrition by the pulmonary plexus, fails because we are dealing with an animal *with*, not *without*, bronchial arteries, and because it applies with equal force to the other tissues of the lungs as well as the cells.

Further reasons are also advanced, drawn from the

manner of termination of the bronchial arteries and from facts of the fetal circulation.

III. Then it is explained that though the pulmonary capillary circulation is not the immediate agent in the nutrition of the cells or in inflammation, still it plays a very essential (secondary in point of time, though not of importance) part in the pathology of pneumonia, because inflammation of the air-cells obstructs in various evident ways aëration, and this must be followed by more or less stagnation of the blood in the pulmonary capillaries, small in degree in the first stage, but complete in the second stage (hepatization), and unless this be borne in mind we cannot understand the morbid anatomy of pneumonia; and, as is fully explained in the paper, there are questions relating to symptoms, progress, and treatment which are not intelligible without a distinct recognition of stagnation of blood in the pulmonary plexus, not as constituting inflammation of the air-cells, but as a necessary sequence of it, and a part of pneumonia.

IV. The question of position of the exudations, whether into or external to the cells, is shortly noticed, and regarded as one of great simplicity, not requiring the microscope for its elucidation, but bearing in the structure of the lung the proof that the exudation must be chiefly into the cells.

The analogy between pleuritis and pneumonia is noticed, in the slight anatomical difference in the tissues concerned, in the exudation being on a free surface in both—in pleuritis tending to become organized, in pneumonia to liquefy. The difference depending on the exudation in pleuritis being on the free surface of a closed sac; that of pneumonia on the free surface of sacs exposed to the air.

V. *Hepatitis*.—The question in regard to hepatitis is noticed very briefly. It is argued that the capillaries of the hepatic artery are the nutrient vessels of the liver and the factor in inflammation; but that the symptoms, pathology, and treatment of hepatitis cannot be rationally explained unless the important facts in the anatomy and physiology of the portal circulation in the liver be borne in mind.

Dr. WILLIAMS said that he had not been able fully to comprehend the meaning of the author in the elaborate and ingenious views just read; but Dr. Morehead, who was his old and valued friend, had apprised him that he was about to communicate a paper on the subject, and requested that he (Dr. Williams) would attend. He was very happy to do so, although the opinions expressed by Dr. Morehead appeared to be in opposition to those entertained by himself. It was upwards of thirty years since he (Dr. Williams) first propounded the opinion that the essential seat of pneumonia is in the great capillary plexus of the pulmonary artery and vein. This view seems to have been generally adopted by the profession; and even during the present session they had had a paper confirmatory of it from Dr. Waters of Liverpool. Dr. Morehead now maintained an opposite view—that the first and essential seat of pneumonia is in the capillaries of the bronchial arteries, the congestion of the pulmonary capillaries being a secondary effect. But all the prominent features of pneumonia declare it to be, from first to last, an affection of no subordinate or diminutive set of vessels, such as those of the bronchial membrane, but of an important vascular plexus standing in close relation with the blood of the whole body: so that, as he (Dr. Williams) had remarked when Dr. Waters' paper was discussed, pneumonia might be represented to be a general or blood disease, rather than a mere local inflammation. He would not reiterate the arguments which he had used on that occasion, but would point out, as an objection to the notion of Dr. Morehead, the remarkable diversity which existed between the two diseases, pneumonia and bronchitis. For if pneumonia always originated in the same vessels that were the seat of bronchitis, there ought to be more or less of a constant tendency of the diseases to pass into each other. There could not be general or capillary bronchitis

without more or less pneumonia; and pneumonia could not exist without a considerable and spreading bronchitis. Yet how different was the fact if we appealed to actual observation. Considering the proximity of their seats in the same organ, it was most striking to observe the marked difference between the two diseases, pneumonia and bronchitis. This difference has reference to their causes, their symptoms, their physical signs, and their anatomical effects. Of course he spoke of the typical forms of the maladies; for he was ready to admit that cases occur in which the diseases may be mixed or in combination, so that we have a broncho-pneumonia, or pneumonia with bronchitis. But these cases are by no means so common as those of the pure diseases, in which their respective characters stand out boldly and distinctly as affections that cannot and ought not to be confounded. The causes of pneumonia would be found to be those acting more generally and profoundly on the bloodvessels and blood than those which excite bronchitis. The latter might result from common chill or exposure to cold; but if the cold was intense or so long continued as to deeply disturb the circulation, as in prolonged cold bathing, or if after fatigue or exhaustion from other causes, or if combined with the operation of deleterious gases, then the great pulmonary plexus would be congested, and pneumonia would be the result. Some causes of pneumonia operate through the blood itself. Thus he might cite an experiment of Magendie, that of injecting phosphorated oil into the veins, and inflammation of the lungs was produced. So febrile poisons and the poison of the rattlesnake and of some fungi, operating through the blood, at once develop inflammation in the capillaries of the lungs, which constitutes a formidable complication in the operation of these deleterious agencies. In all these and similar causes of pneumonia we recognize influences which seriously and extensively affect the blood and its circulation, and develop their operation on the great blood purifying organ; and if we study the symptoms of pneumonia, we find the same evidence of profound and general impression on the system. The rigor is more marked and more constant than in any other inflammation, and was mentioned by Chomel and Grisolle as a symptom characteristic of pulmonary inflammation. Then follows an equally distinctive intensity of heat. How often when applying his ear to the back in examining the chest had he been struck by the feel of pungent heat in the patient's body—a heat often rising several degrees above 100° Fahr. So in sthenic cases at this period the face is flushed with the throbbing headache of fever; the skin dry; the urine scanty, dark, and without its normal saline matter, which is retained in the inflamed lung. And if to these symptoms we add a strong, frequent pulse, we have such a condition of inflammation, local and general, that it is no wonder that bloodletting should be trusted as the great remedy. He (Dr. Williams) had used it frequently in years long past, and with the best effects; but he admitted that of late years it was very rare to meet with a case in this state, and bloodletting was seldom called for. The flush soon gives place to pallor, and the pulse loses its strength and fulness, and assumes the liquid jerky character of a half-filled artery; the blood, in fact, being in great part arrested in the inflamed lung, and, therefore, not available for the general circulation. No wonder, then, that now an opposite treatment is called for, and that stimulants become the best remedy. And now, if we compare the corresponding symptoms in bronchitis, we shall find a marked difference. The rigor, if present, is less marked; the heat and flush are more transient, and less intense; the pulse, though frequent, has neither the strength of the first stage of pneumonia, nor the collapsing liquidity of the second. In extensive bronchitis it becomes small and frequent as the disease advances; and instead of the pallor of pneumonia from the arrest of blood in the lung, we have the purple lividity of the surface from the blood circulating in an imperfectly arterIALIZED state. Again, the blood-stained expectoration of pneumonia is another

token of its origin in a large and blood-filled capillary plexus, beyond the mere mucous secretion of bronchitis. Then, if we come to the physical signs of the two diseases, we find further evidence of their difference, even in the commencement. In bronchitis the signs are those of bronchial obstruction, more or less complete. Rhonchi attending inspiration and expiration, first lengthening both, subsequently shortening the former and prolonging the latter, with more or less diminution of the proper vesicular murmur. In pneumonia the first sign—the crepitation—comes at once from the vesicular tissue. There may be no general or bronchial rhonchi; but at the seat of the inflammation the fine crepitation comes out sharp and close to the ear at each inspiration, and so confined to the spot in the vesicular tissue of the lung that if you remove your ear to a spot an inch or two from it you cease to hear it altogether. Like vesicular respiration, it is heard only in the spot in which it is produced; and unlike tubular respiration and rhonchi, which are commonly heard to some distance. In the second stage of pneumonia the consolidation develops the tubular sounds of breath and voice, while in advanced bronchitis there are no such signs. In the naked-eye anatomical results of the two diseases we find the distinction equally marked. In bronchitis the lung is distended with air imprisoned in the obstructed bronchi; spongy and frothy on incision; and although parts are often much congested from weakened circulation and impaired aëration, yet this condition is not sufficient to supersede the air in the cells, and there are no signs of consolidation. In pneumonia, in the first stage there is still air in the cells; but the lung feels heavy, pits on pressure, and on incision exudes abundantly frothy serum or spumous blood. The transition to the stage of hepatization is marked by the gradual substitution of solid deposit for the air and part of the fluid previously present. Seeing, then, that bronchitis, the acknowledged affection of the bronchial arteries, so entirely differs from pneumonia in its whole course, could any further light be thrown on the subject by an appeal to microscopic anatomy? In his early attempts in this mode of investigation he (Dr. Williams) had been struck by the large size and number of blood-filled capillaries, even in the earliest stage of pulmonary inflammation; which forcibly suggested the idea that they were pulmonary, and not merely bronchial. Subsequent observers had come to the same conclusion; Dr. Waters being the most recent. Still this field was open to further investigation, which would be more conclusive than speculative reasonings on the subject. The attempt of Dr. Morehead to explain the development of pneumonia from a primary affection of the bronchial capillaries was ingenious, but far-fetched and wanting in simplicity. Why should not this very characteristic inflammation have its origin as well as its seat in the pulmonary capillaries?—which, conveying arterial blood, and backed by the force of the right ventricle, have in themselves all known capabilities of inflammation; while their intimate relation with the whole mass of blood in the body serves to explain much of those remarkable features which distinguish pneumonia from the common group of visceral inflammations.

Dr. SIMON said that he, like Dr. Williams, had some difficulty in following Dr. Morehead's paper. He gathered, however, that the author, while he considered that in pneumonia the bronchial capillaries were the primary seat of pneumonia, yet that the pulmonary capillaries were also affected with congestion and stasis, and that the air-cells were the seat of exudation. He in this respect coincided with the observations of the best recent pathologists. In a paper in the Provincial Medical Transactions for 1844 (p. 440) the speaker described the condition of the pulmonary vessels in pneumonia, from preparations in which those vessels were injected from the pulmonary veins. The pulmonary capillaries were much enlarged, irregularly swollen, and tortuous in the bronchial tubes entering the inflamed air-cells, which were filled with exudation; and it was very remarkable to notice the

abruptness with which the injection stopped short at the point where stasis was established. The rapidity with which the disease usually passed through its whole stages, from the first ushering in of inflammation to the complete restoration of the junction of the lung, was surprising. Active congestion, stasis, exudation into the whole of the air-cells, solidifying the affected lung, softening and conversion into pus of the exudation, its complete evacuation, and the readmission of air into the cells, the removal of stasis and re-establishment of circulation in the capillaries, succeeded each other in steady progression, and in doing so occupied, on an average, only the short space of nine or ten days. The speaker owned that every time he witnessed these remarkable changes he was filled with wonder. It must be allowed that both the bronchial and pulmonary capillaries were affected in pneumonia, when it was considered that the bronchial vessels were distributed to the whole structure of the lung (bronchial tubes, connective tissue, interlobular structure, and pleura—structures which were all involved in the inflammation), and that they not only immediately adjoined, but anastomosed extensively with the pulmonary capillaries. The existence of this anastomosis had been established by Ruysch, Haller, and Reisseisen, as well as by Guillot, Rossignol, and Adriani. The question as to whether the bronchial or the pulmonary capillaries were first affected in uncomplicated acute pneumonia would perhaps never be brought to the test of direct observation, owing to the difficulty of obtaining the lung at the earliest stage of the disease; it would therefore probably have to be decided by a process of reasoning. In some of what might be termed the marginal pneumonias the primary vascular seat of the affection could be fixed upon. Thus it could with precision be said that the disease commenced in the pulmonary capillaries in those cases depending on passive congestion, from obstacle to the flow of blood along the pulmonary veins, as in hypostatic pneumonia, and in pulmonary apoplexy, which differed from pneumonia in the character of the exudation (being almost pure blood, composed of fibrin and red corpuscles, with a few white; while in pneumonia there were, in addition, numerous exudation—white—corpuscles), and in the extent and kind of limitation, but agreed with it in the seat of the exudation, its stages, and the existence in many cases of pleuritic exudation superficial to the part affected with pulmonary apoplexy. In bronchitis, a subject to which the attention of the Society had just been called by Dr. Williams, the injections described in the paper alluded to showed that the pulmonary vessels were enlarged, tortuous, varicose, and looped on the inner surface of the bronchial tubes; the bronchial capillaries, which were superficial to the pulmonary, were also undoubtedly affected.

Dr. SALTER wished, in the first place, to correct an erroneous impression to which, from some remarks that had fallen, the paper seemed to have given rise—viz., that the author meant in any way to confuse bronchitis and pneumonia, or to imply any connexion between them. What the author evidently meant was, not that in pneumonia there was any bronchial inflammation, but that true pneumonia, having the recognized symptoms, signs, seat, and morbid anatomy of pneumonia, might nevertheless be due to derangement, not of the pulmonary, but of the bronchial vessels. The anatomical question involved in the paper was a very interesting one—namely, the fact of communication between the two independent circulations—bronchial and pulmonary. The purpose served by these two coexistent circulations in the lungs (the nutrition of the lung-tissues with arterial blood and the carrying off of venous blood without its going to the left side of the heart) is such as to imply that there should be no communication between them. Such a communication, however, undoubtedly existed. But it had been shown by Rossignol and Adriani that the communication was such as not to involve a mixture of the bloods. Thus the bronchial arteries could be injected from the pulmonary

veins, and the pulmonary veins from the bronchial arteries, in both cases the blood being arterial; but the bronchial vessels cannot be filled from the pulmonary arteries—that is, venous blood cannot get into the bronchial circulation. These observers had also shown that the mucous membrane of the smallest bronchiæ was also supplied from the pulmonary artery; and there was one circumstance, otherwise difficult of explanation, that this distribution satisfactorily explained—the fact, namely, that the production of slight asphyxial congestion by the shutting off of air, as for instance in asthma, was always attended with exudation and discharge of little pellets of bronchial mucus. The circulation in which engorgement was produced by the shutting off of air being the pulmonary, and not the bronchial, it would be difficult to understand how it should give rise to mucous exudation unless the pulmonary vessels had to a certain extent a bronchial distribution. But such being the case, the phenomenon was perfectly intelligible. He (Dr. Salter) thought that the author's definition of the inevitable seat of inflammation, based on the word "nutrition," gave to that word too narrow a signification. When inflammation is said to be a disturbance of nutrition, the word nutrition is taken in its widest sense, as standing for all those vital or other processes of which the capillaries are the seat. In relation to the arterial condition of the blood, there was not really that difference between pulmonary capillaries and other capillaries which had been supposed. No doubt the blood delivered to the pulmonary capillaries was venous, but it immediately became in them arterial, and in that state left them, so that while in the systemic capillaries it passed from arterial to venous, in the pulmonary it passed from venous to arterial, and was probably as much arterial in the latter as in the former; so that as far as the arterial character of the blood went, the pulmonary capillaries might as well be the seat of inflammation as any other.

SURGICAL SOCIETY OF IRELAND.—APRIL 6.

Dr. WILMOT, President of the College, in the Chair.

TUMOUR ON PERICARDIUM CAUSING HYDROTHORAX ON ONE SIDE.

DR. BENSON said he had a morbid specimen to exhibit which appeared to him to be interesting in many points of view, its peculiar locality, its size, its structure, the age of the individual in whom it was formed, and more especially the symptoms and physical signs which attended it during life, all seemed to render it not undeserving the notice of the Society.

He would first read the case, as noted down by Dr. Benson, jun., and then make a few observations on it:—

L. J., a female, aged 16, had resided in the country, and was admitted into the City of Dublin Hospital on March 13, 1866, for a disease of the chest.

The patient stated that about a month previous to her admission she was seized with a dull pain in the left side of her chest, and in the shoulders, without cough or any other prominent symptom, nor could she refer the commencement of this uneasiness to any exposure to cold or wet. She continued in her situation as nursery-maid, going through her usual business for about three weeks subsequently, after which a medical man recommended her to come to Dublin for advice. There was then extensive and complete dulness on percussion over the whole of the left side of the chest, it having been found impossible to elicit a clear sound in any part of that side. Auscultation revealed no positive sign whatever. Mensuration enabled us to discover a difference of three-quarters of an inch between the circumferences of right and left sides, the latter being the greater. The intercostal spaces were bulged, and the parietes so tense and hard that it was with difficulty one could discern the ribs from their interspaces. The area of dulness extended beyond the mesial line, and

the impulse of the heart was felt about that same line, and somewhat lower down than it is in health. Very loud supplemental respiration was heard in the right lung, which appeared free from organic disease. Dyspnoea was not a prominent symptom, though the patient preferred the sitting posture rather than the recumbent.

The face was somewhat congested; the pulse was so extremely irregular, intermittent, frequent, and weak, that it was found impossible to count the beats accurately. The mean frequency, however, after several observations was considered to be about 100.

On the 14th, the day after her admission, she was ordered a blister, eight inches by six, to the left side and the following pills:—

℞ Pilulæ hydrargyri, gr. vi.
Pulveris scillæ, gr. iii.
Pilulæ coloc. cum hyos. gr. iii.

Fiat massa. Divide in pilulas tres sumatur una sexta quaque hora.

On the 16th, a blister, four inches by three, was placed under the left clavicle. Next day, 17th, upon auscultating the left side, we found no râles whatever, and but very feeble respiration in the upper and back part of the same side. There was very slight bronchophony of a peculiar ringing metallic kind, in that part of the left side where respiration was audible, but not having any of the egophonic character.

℞ Potassii iodidi, gr. xxx.
Tincturæ opii ℥xxx.
Spiritus chloroformi, ℥i.
— ætheris nitrosi, ℥ij.
Misturæ camphoræ ad. ℥viiij.

Fiat mistura. Sumatur cochleare amplum tertia quaque hora.

On the 18th it appeared she had gotten a sharp attack of bronchitis from exposure to cold. The râles peculiar to this complication were audible all over the previously sound side, and slightly so in the diseased side. Some slight dulness was perceptible at this time at the back of the right lung. The dyspnoea, which was before but slight, now became formidable orthopnoea, the patient having to sit up in bed both by night and by day.

On the few following days of her life, she got brandy and various stimulants, was dry cupped, blistered again, &c. &c.

The bronchitic râles on the 21st were extremely loud all over the right side, and on the left they were audible, not only along the side of the spine, but could be distinctly traced outwards to a distance of six or seven inches from the posterior mesial line. The orthopnoea was this day very distressing indeed.

The 23rd the sufferer died.

Autopsy.—On opening the chest an immense quantity of clear serum escaped from the left pleural cavity, and a small amount from the right.

The left lung was found to be compressed against the spine, and carnified, and contained numerous very small abscesses. The left pleura was everywhere somewhat opaque and thickened, though perfectly smooth and without lymph or adhesions; but that part covering the pericardium seemed, at first sight, to be converted into a thick, fatty mass, with separate collops, somewhat resembling the appendices epiploicæ on the large intestine, but not so free.

Upon handling these masses, however, it became evident they were not composed of fatty material. Though of nearly the same colour as fat, they were much harder and less elastic, and were quite friable between the blades of the forceps. On opening the pericardium, a considerable quantity of bloody serum escaped from its cavity, and now a new and unexpected condition appeared. It was found that the pleura covering the anterior aspect of the apex of the pericardium, corresponding to the base of the heart, and the pericardium itself in that place, were converted into a dense mass of the same material as those collops spoken of above. This tumour measured about three

inches in thickness, four in breadth, and five in length. It was conical, or rather wedge-shaped. Its base lay above at cervico-thoracic septum, and its apex, or the thin edge of the wedge, corresponded pretty nearly to the apex of the heart. The under surface of the tumour lay in close apposition to the upper or anterior aspect of the heart, which was somewhat displaced downwards by this growth, as well as towards the right side by the effusion. The heart itself was remarkably small, but not organically diseased. The tumour completely enveloped a part of the transverse portion of the arch of aorta, the upper half of the superior vena cava, and parts of the pulmonary and innominate arteries and veins, the left carotid, and left subclavian vessels, besides the anterior and lateral aspects of the thoracic portion of the trachea. This latter tube bore off from the œsophagus the direct pressure of the morbid growth, yet from its indirect pressure one might have expected that there would have been some dysphagia. Such, however, does not appear to have been the case. We should not expect that there would have been dyspnoea specially depending on any pressure on the trachea or bronchi, for the tumour has evidently been formed around these tubes, as also around the vessels in this neighbourhood, without exerting any pressure. At the upper part and left side of the tumour's base a fluctuating spot was detected, which, when cut into, was found to contain thick, bloody, purulent matter, having very much of the cerebriform appearance. The microscopic characters of this tumour were rather obscure. A thin section of it when placed under the lens showed itself to consist almost entirely of myriads of spherical corpuscles, smaller than pus or blood cells, each having one large nucleus in the centre, and very much resembling scrofulous tubercular matter, both as to size and general appearance. Though no cancer cells of any kind were visible, it was thought probable that the tumour was malignant in its nature.

Dr. Benson then proceeded to say that this morbid growth had been subsequently examined by Dr. John Barker, who thought it malignant, though he could scarcely say that there were cancer cells in it.

It appeared very strange that such a mass as this should have formed in that particular situation, and the symptoms connected with it were somewhat peculiar. This large mass had formed on the upper part of the pericardium, and there was no disease whatever of the pleura itself. The cavity of the pleura was enormously distended with a clear serous fluid, and the only change the membrane underwent was that blanched satiny appearance which the peritoneum gets in ascites. It was a case of hydrothorax then, and it was peculiar in some respects; hydrothorax was more generally met with on the two sides, and especially so if it depended on Bright's disease or any interruption to the circulation; so much so that the accumulation of a fluid on one side was given by some writers as a diagnostic feature by which empyema might be distinguished from simple hydrothorax. But a tumour might so press on the vessels on one side as to cause obstruction to the circulation to take place on that side only, and in that way one might have hydrothorax, as in this case, affecting only one side. The side was considerably enlarged owing to the quantity of fluid which accumulated in the cavity of the pleura. It was, therefore, plain that the distension of one side only does not prove that a disease may not be hydrothorax.

There were some other points of interest in the case; one was that the intercostal spaces were dilated and raised to a level completely with the ribs. This was so rare in cases of hydrothorax that Dr. Stokes, in his valuable work on "Diseases of the Chest," said he never saw an instance of it. He (Dr. Benson) had seen some instances, and in the present case it was remarkable. The enlargement was obvious even to the eye, and on measurement was three-quarters of an inch more than on the other side. The intercostal spaces were dilated and pressed out on a level with the ribs, disproving the explanation which Dr. Stokes gave of the puffing out or yielding of the intercostal muscles. Dr. Stokes stated what he considered to be the fact, that the

intercostal spaces were never pressed out to the level with the ribs, except where there was inflammation of the pleura, and he thought that this inflammation gave rise to paralysis of the muscles, and that they then yielded to pressure from within which they would not have done but for this inflammation of the pleura; yet here was a case where there was not any inflammation of the pleura, and yet the intercostal muscles had the appearance of being paralyzed and the spaces dilated. Another point was that the respiratory murmur was heard six or seven inches from the spine. The left lung was so pressed back to the spine that when examined it was found to be carnified. Though this murmur might not be easily accounted for, yet he supposed its occurrence was a fact every one had met with. It appeared to him that perhaps the sound was conveyed by the walls of the thorax, along the ribs. The lung was incapable of admitting air into its cells, and could only allow it into the larger tubes and very little there, and yet the respiratory murmur was heard six or seven inches from the spine. As to the nature of this tumour it was not likely to be malignant in a person so young as this girl, who was only 16 years of age. She did not show by her countenance any sign of the existence of malignant disease in her system. Her face was florid and congested; she was not at all emaciated; she was only ten days in the hospital, and had been, she said, not more than a month complaining before her admission. Her death was, obviously, not occasioned by any malignancy in the tumour, but by the hydrothorax to which it gave rise by its pressure on the vessels, thus totally depriving her of the use of one lung, while an acute attack of bronchitis rendered the other lung incapable of supporting life.

Mr. B. WILLS RICHARDSON read the following paper on the question as to the frequency of

ABSORPTION OF THE CRANIUM BY THE PRESSURE OF ORDINARY NON-CONGENITAL ATHEROMATOUS TUMOURS.

You may recollect, Sir, that during the debate upon Professor Hargrave's communication at the meeting of the Society on the 2nd of last February, it was stated by Mr. Symes that he had seen the cranium absorbed by the pressure of sebaceous cysts. As I thought absorption of the cranium by the common sebaceous cyst to be a very unusual circumstance, I ventured to ask Mr. Symes if he had ever an opportunity of verifying by post-mortem examination that ordinary sebaceous or atheromatous cysts usually caused absorption of the underlying cranial bone. It struck me on that occasion the fingers might be deceived regarding the exact site of the cups or depressions in which sebaceous cysts are imbedded, and that condensation of the scalp at the brim of the cup would give the sensation to the finger that it was of an osseous nature, and the surgeon might thereby be induced to believe the depression was actually in the bone, whereas it was in reality formed in the superjacent scalp. Within the last few days I had an opportunity of removing one of these cysts from the vertex, and found that it was lodged in a regular depression, with a tolerably hard margin. I ascertained, however, after the extraction of the cyst, that the depression was movable, for, on placing the end of one of my fingers in it, I could, with some trifling force, displace it backwards and forwards. If, then, Sir, I was not deceived in this manoeuvre, it appears to me to be quite evident, that cup-like nests may be formed in the scalp for the lodgment of atheromatous tumours, and that it does not follow, if we feel depressions of the kind, that absorption of the cranial bone has taken place.

My friend, Mr. Fleming, took an opposite view to the one I raised regarding the rarity of absorption of the cranium by ordinary sebaceous cysts, and seemed to think that they frequently caused absorption of the underlying bone. And he not only stated so at the meeting referred to, but reiterated the opinion at a subsequent meeting after Mr. Stapleton had exhibited a tumour of the scalp which he described as having caused absorption, I believe, of the frontal bone. And, again, at the meeting

of the 2nd of March, when he presented to the Society a small tumour which he described as an ordinary atheromatous tumour, and which he removed from a man far advanced in life, and who had the tumour about twenty years. So positive was Mr. Fleming that the cranium was absorbed by the pressure of that small sebaceous cyst that he offered to show the patient to any gentleman who wanted to satisfy himself as to whether tumours of this kind ever formed indentations in the skull, and he was most explicit in stating "they would find in this case a distinct cavity in the skull corresponding to that portion of the tumour which was bound down *in situ*. He begged to repeat that there were cases in which these tumours, distinctly atheromatous, caused, from the length of time they existed, an indentation of the skull. There could be no doubt but that this tumour was quite superficial to the periosteum and pericranium." If I am not in error, Professor Hargrave himself seemed to think that ordinary sebaceous cysts rarely caused absorption of the cranium; and, as well as I can remember, Mr. Collis and Dr. Wharton were of a similar opinion, and coincided with the view which I put forward.

It is scarcely necessary to observe that this question has resolved itself into a pathological one, and can therefore only be satisfactorily solved by pathology. We all agree that the cysts are frequently imbedded in cups or depressions on the head, the question being in what structure are they usually situated. Are the cups formed in the scalp alone, or in the bone, or in both these structures? In order, if possible, to collect evidence decisive of the question—whether ordinary atheromatous cysts usually caused absorption of the cranium—I placed myself, immediately after the February meeting alluded to, in communication with several gentlemen of well-known pathological experience, and who would therefore be most likely to throw light upon the matter. And I take this public opportunity of thanking the gentlemen to whom I wrote upon the subject, for the promptitude with which they replied to my queries. Dr. Barker, the curator of our College Museum, has informed me that there is no specimen in the Museum demonstrative of absorption of the cranium in the manner alluded to. It might be said that people do not often die from the effects of sebaceous cysts of the scalp, and therefore the rarity of such museum specimens. Individuals with these cysts, however, die of other diseases. Subjects, for instance, Mr. Macalister, the excellent demonstrator of anatomy in the school of the College, informs me, have been brought into the dissecting room here, in whose scalps sebaceous cysts existed, and yet the cranium was not indented by any of them. If I do not mistake, Dr. Mapother has seen similar cases.

If I may be allowed to theorize, the fact, Sir, that persons with sebaceous cysts of the scalp rarely die of them, may be used as an argument against their having the power to effect cranial absorption. Because, if cranial indentations are so frequent in the practice of others as in that of Mr. Fleming, it is difficult to understand when these tumours are multiple, why the brain should not occasionally suffer from the proximity of the mischief going on in the skull-case.

Mr. Timothy Holmes, the accomplished editor of the "System of Surgery," was so kind as to write to me to say that he had only "seen a few cases in which sebaceous or cystic tumours of the scalp have been accompanied by absorption of the cranium, and in these cases," he says, "the tumours have (he thought in all) been congenital, and not the common atheromatous tumour, so that it is impossible to say whether they had caused absorption of the bone, or had interfered with its complete formation, or had been developed in a part where congenital deficiency of bone existed."

The cases he could remember were but three. He assisted Mr. Prescott Hewett in removing a cyst from the corner of the orbit in a girl about twelve, and "which was found to pass through the roof of the orbit and lay in contact with the dura mater." Mr. Athol Johnson had, he

thought, "two cases at the Children's Hospital." The cups in these cases, he imagined, are formed in the bone of the skull itself. He also mentioned that there is in the Museum of St. George's Hospital a specimen in which there is a similar depression in the internal table of the skull from the pressure of a congenital cyst, which was included in the ossifying cranium.

In some other letters which I received from Mr. Holmes upon this subject, he mentions that "Mr. Hewett has notes of ten cases, in all; some congenital, others not." At all events, when we deduct the congenital ones from the number, assuming for a moment the remainder were ordinary atheromatous tumours, they afford but a limited support, indeed, to the opinion, that absorption of the cranium was a frequent consequence of the pressure of common sebaceous cysts. Mr. Holmes, I should here observe, wishes it to be understood that his opinion is the result of his own limited experience and not of any special investigation of the subject.

There is but one specimen I am informed by Mr. Flower, the curator of the College of Surgeons Museum in London, in the college pathological collection, in which perforation of the cranium was caused by the pressure of a sebaceous tumour. From the history of this case it appears likely to have been a congenital and not an ordinary sebaceous cyst. The specimen was taken from a girl, *et. 17*, who was admitted into the Hôpital Necker, Paris, in November, 1842, under the care of M. Lenoir, with a small sebaceous tumour of the size of a walnut in the upper and middle part of the frontal region, a little beyond the roots of the hair. This tumour had been first noticed when the patient was *two years of age*; it was then very small, and its increase had been gradual. Some years back an incision was made into it, but the cyst was not removed. In cutting into the cyst, M. Lenoir found that it was lodged in a deep cup-like cavity in the frontal bone, to which it was very firmly attached. The whole cyst was, however, got out. Two days afterwards erysipelatos inflammation made its appearance about the scalp, and the patient sank on the tenth day after the operation. In this specimen the frontal bone was perforated. It was presented to the museum by Mr. Prescott Hewett.

If you bear in mind that this tumour was first discovered at two years of the patient's age; that it took fifteen years to grow to the size of a walnut, it is probable it was also growing for the whole of the first two years of the patient's life, and that it likewise was a congenital tumour. From the fact also of this specimen being a French one, and considered by Mr. Hewett worthy of being deposited in the London museum, I argue that absorption of the cranium by ordinary sebaceous cysts must be exceedingly rare, or this specimen would hardly have been deemed worthy of being imported from Paris. Be this as it may, it can hardly be called an ordinary sebaceous or atheromatous cyst.

The Edinburgh College of Surgeons Museum is as barren of specimens of cranial absorption by ordinary atheromatous tumours as our own and the London Colleges are; for Dr. Wm. Sanders, its Curator, took the trouble to search it carefully for me, but could find no preparation in it of atheromatous tumour of the scalp, causing absorption of the underlying cranial bone.

Mr. Savory of St. Bartholomew's Hospital, in London, writes to me that he could not find in the hospital museum any specimen of the kind I referred to.

Mr. Wilks of St. Thomas's Hospital obligingly searched the hospital collection, and states that they have not any specimen showing absorption of bone by sebaceous tumours, and considers the case I have mentioned to be very rare.

Mr. Spencer Cobbold tells me that there is not in the Middlesex Hospital a specimen of the kind I described in my letter to him; nor could he remember any such specimen in the Edinburgh Anatomical Museum of which he had the charge for several years.

Mr. Paget, who, I am happy to say, has quite recovered

from his recent illness, informs me that he does not remember to have seen any cases of "ordinary atheromatous tumour of the scalp that caused absorption of the underlying cranial bone."

All the tumours of this class that he has seen imbedded in bone have been congenital cutaneous cysts, or, if not congenital, formed in very early life.

It would appear, Sir, if I may judge by the letter I am about to read, that French crania are as uninfluenced by ordinary sebaceous cysts as English skulls, and probably also most Irish ones. Although this letter is the last upon my list, I received it several days ago, but thought it better first to read all the English answers I could get to my questions, and wind up the correspondence with this most interesting note:—

Paris, 16th March, 1866.

"MONSIEUR, HONOURÉ CONFÈRE, — You ask me first if I have seen cases in which an ordinary atheromatous tumour of the scalp has caused absorption of the subjacent bone?

"2nd. If the cups or depressions seen in these cases, are formed in the bone or in the tissues which cover it, or if they are formed in both?

"This is my answer.

"1st. I have never seen cases in which an atheromatous tumour of the hairy scalp caused absorption of the subjacent bone. I add that is impossible, because these tumours are nothing else but cysts, which cysts have for their starting point the sebaceous follicles of the hairy scalp, and consequently always are developed on the side of the epidermic surface of the skin. The aponeurosis of the occipito-frontalis muscle is an obstacle which the cyst could not surmount; whereas, it finds an easy development on the side of the epidermic surface of the skin.

"2nd. The cases of absorption of the bones of the skull are entirely foreign to the cases of sebaceous or melicerous cysts of the hairy scalp.

"The fungous tumours of the dura mater can wear out the bones from the inside to the outside. The pressure which they exercise on the bones of the skull, the rising of the brain at each contraction of the heart, seem to me to explain perfectly the bony atrophy which sometimes goes as far as perforation.

"I beg you, Monsieur, and very honoured Confère, to accept the assurance of my friendship.

"CRUVEILHIER."

A somewhat analogous cause of perforation, but from without inwards, I may remark, is occasionally seen. I allude to the destruction of the cranium from the pulsatile pressure of arterio-venous aneurism, originating in the scalp. And that it may be perforated by other tumours is well known to surgeons, and is also evident from some of the opinions and cases I have already alluded to.

I must now take the liberty of again reminding the Society that the question, whether absorption of the cranium is a usual result of the pressure of ordinary sebaceous cysts, has resolved itself into a purely pathological one, and therefore can be only conclusively decided by pathology. We all know that scalp sebaceous cysts may be lodged in cups or depressions, but we disagree as to the structure they are situated in. Mr. Fleming, as I before stated, took issue with me upon the subject, and remarked, when I raised the question, that he had frequently observed these cups in the bone. That opinion, he repeated at two of our more recent meetings, and on the last occasion was most positive, a small atheromatous tumour of the scalp, which he then presented to the Society, had caused absorption of the cranium. I do not for a moment doubt the accuracy of his observation, but I, notwithstanding, believe such a result must be extremely rare in the practice of others. As I have stated, this question can only be unmistakably decided by post-mortem examination, and therefore it is to be hoped that those gentlemen who believe that absorption of the cranium is a common result of ordinary atheromatous tumours will send the first specimens of this description they meet with to our

College Museum which does not contain a specimen illustrative of the point. When we see the specimens, I, and I am sure those gentlemen who think with me that this is a most unusual result of ordinary atheromatous tumours, will hasten to give full credit to the gentlemen who may send such interesting donations to the College. I am myself, however, so very dubious as to the frequency of absorption of the cranium by these atheromatous cysts, that it will require very unequivocal specimens, indeed, to induce me to change my opinion, and I will not be convinced that absorption of the cranium is a common result of ordinary non-congenital atheromatous tumours, or of tumours that are discovered so soon after birth that it is doubtful whether they are congenital or not, unless I see the tumours actually lodged in the depressions in the cranium. When a few such specimens are produced, I shall then, and not till then, admit that absorption of the cranium by ordinary sebaceous cysts is more common than I hitherto thought it to be.

Mr. SYMES said that the patient, to whose case he referred some nights back, was a policeman, aged 19 years. The tumour was situated in the frontal region, and might be called an ordinary atheromatous tumour; whether congenital or not, he was unable to say, but it had existed for some years. He was perfectly certain he had his finger in that man's frontal bone, and he left some of the tumour in the cavity unremoved. Instead of benefiting the patient by the operation, he did him an injury, for he remained in the hospital for a long time in consequence of particles of the bone exfoliating, and he had some difficulty in getting him taken back into the police force. It was said these tumours were obstructed sebaceous ducts. He remembered seeing Sir William Fergusson taking a number of them from a woman's head, and Sir William on that occasion altogether denied that they were obstructed sebaceous follicles.

Dr. FLEMING said if he had any idea that Mr. Richardson intended to bring forward such an elaborate paper on this subject, he should perhaps have been prepared with cases, many of which had come under his observation bearing on the question. The matter was hardly worthy the elaborate treatment it had received from Mr. Richardson. He (Dr. Fleming) merely stated some facts respecting cases he had treated, and he had no hesitation in repeating his former statement, that in many of these cases—he did not say in all—of sebaceous tumours in the scalp, there were indentations produced by progressive absorption of the bone. He thought there were special situations, such as that alluded to by Mr. Symes, in which this effect was more likely to occur than in others—that is, where from the site of the tumour it is more subject to pressure from without; for instance, in a situation where the hat or cap would produce some pressure upon it, he thought this pressure would have a tendency to produce a certain effect on the skull underneath. He was aware of more than two cases in which tumours existed of this description, and where indentations existed, and these tumours were not congenital and not subpericranial. They possessed diagnostic peculiarities by which they could tell that they were atheromatous, and most of them were movable, which would not be the case if they were under the pericranium. In the cases he had seen, the indentations might have been caused by pressure from without, but that they did exist he was perfectly satisfied. He had removed tumours from the temporal region. In that special locality there was a difficulty in placing these tumours under the class of atheromatous tumours (for their situation gave them a peculiar character); but in these cases also he had seen indentations, and on one occasion he assisted a gentleman (who was in the room) a short time ago and Sir William Wilde in removing one which was situated near the orbit. Unquestionably they were not subpericranial, and unquestionably they were indentations. The tumour which he removed the other day had existed for at least twenty years.

Dr. HAMILTON said there were two distinct issues in

respect to this question which Mr. Richardson did not appear to keep sufficiently separate; one was, whether it was a general rule for tumours of this kind to produce indentations in the skull; and the other, was it possible for them to do so? Every practical surgeon would admit that it was not a rule, but an exception to the rule, and he believed it did occasionally occur that indentations were caused by absorption of the tendon of the occipito-frontalis resulting from a peculiar condition of the tumour.

Mr. CROLY said he did not think any of the surgeons with whom Mr. Richardson communicated said he had dissected scalps to see whether such indentations existed. This was a matter to be tested by actual examination and dissection of the scalp. They all knew that it was laid down in books of surgery that dislocation on the dorsum of the ilium was a result of hip disease, yet, as Mr. Richardson on a former occasion had shown, but few cases of the kind were to be found in museums. He thought it was not unreasonable to suppose that a slight indentation might occur in the outer table of the skull without the brain being affected.

Mr. RICHARDSON—With regard to the observation of Mr. Fleming that this matter was not worthy of the trouble he had gone to, he would observe that he thought absorption of the bony covering of the brain well worthy of the surgeon's investigation. Mr. Fleming could scarcely forget that he himself made a special communication on the subject of absorption of the cranium by an ordinary atheromatous tumour on the last night of meeting. In reply to Mr. Croly, he would remind him that the gentlemen with whom he communicated on the subject had considerable pathological experience, and he was sure, if indentations of the skull were a common result of ordinary atheromatous tumours, they would have seen specimens of the kind. Mr. Croly seemed to misapprehend his argument regarding head symptoms in such cases. What he (Mr. R.) meant to convey was, that if absorption of the cranium was so common a result of ordinary atheromatous tumours that the cerebrum ought occasionally to suffer from the mischief going on in the bone, in cases, for instance, in which several existed in the same scalp, and in which cranial absorption ought to be extensive, according at least to those gentlemen who believe it to be a common occurrence. In answer to Mr. Hamilton, he would remind him that he commenced his paper by stating that he believed absorption of the cranium by ordinary atheromatous tumours a most unusual circumstance, and ended it with the observation, that when some few specimens of the kind were shown to him he would then admit absorption of the cranium by ordinary sebaceous cysts to be more common than he now considered it to be. This, it must be understood, was not a denial that it could not take place at all, but only that such must be very rare. Mr. Richardson did not consider Mr. Symes' case to be an ordinary atheromatous cyst.

The PRESIDENT stated he thought Mr. Symes' case a congenital one.

EXFOLIATION OF PORTION OF LOWER JAW AFTER FEVER.

Dr. GRIMSHAW exhibited a portion of the upper jaw bone of the right side which had exfoliated immediately after an attack of fever.

OBSTETRICAL SOCIETY OF DUBLIN.

14TH APRIL, 1866.

Dr. HARDY in the Chair.

Dr. ARTHILL read a paper on

INFLAMMATIONS OF THE BLADDER AND VAGINA.

He stated that affections of the bladder were among some of the most distressing to which females were liable, and remarked that less attention had been paid to this subject by writers than to almost any

other, Dr. Churchill alone among authors having specially alluded to the subject. Dr. Atthill classed these affections of the bladder under three heads—namely, 1st, those in which inflammation of the mucous membrane of the bladder occurred alone as a simple and uncomplicated disease; 2nd, those in which inflammation of the bladder generally in a chronic form existed, but was complicated by some inflammatory or abnormal condition of the vagina or uterus; and 3rdly, those in which, while the patient referred all her symptoms to the bladder, that organ was healthy, the case being one of that class (termed by Dr. Churchill "reflex irritation of the bladder") in which the irritation of the bladder was caused and kept up by some unhealthy state of the vagina or uterus. The first of these forms being more within the province of the surgeon than of the obstetric practitioner, was on that account only briefly alluded to, one case being mentioned as remarkable mainly on account of the large amount of pus secreted daily for some time with comparatively little constitutional disturbance. This case terminated in perfect recovery.

In speaking of the second form, particulars were given of the case of a young unmarried lady who had been attacked more than eight years previously with acute inflammation of the bladder, but the affection having been either overlooked or neglected, it had become chronic, and the patient's life rendered a burthen from the distress caused by the constant desire to micturate. She was quite unable for several years previous to pass more than from an hour to an hour and a half with passing, or what was more distressing, straining to pass water, and this whether by day or night. The bladder having been examined proved not to contain either calculus or tumour; but pus being detected in the urine, Dr. Atthill determined to treat the case as one of chronic inflammation of the bladder, hoping that the inflammation of the vagina, which was also present, and which he thought was a secondary affection, would subside without his having recourse to special treatment for its cure.

The treatment pursued was the injection of the bladder twice a week with the following solution: Nit. arg., gr. x.; vini opii, gtt. xx.; aq. dist., ℥ij. After a time the strength of this solution was doubled. The result was striking, the patient being able at the end of a month to retain urine for three hours by day and for five by night; but as the vaginitis did not subside the vagina had to be treated separately by brushing it over with a strong solution of nitrate of silver. At the expiration of two months from the time that treatment commenced this patient was enabled to return home in the enjoyment of great comfort. The treatment employed in this instance of injecting the bladder with solution of nitrate of silver was, Dr. Atthill stated, strongly recommended by the late Dr. Hutton in similar cases. The third form was dwelt on at some length. The most common cause of this distressing affection was stated to be, in the author's opinion, vaginitis—not the acute form, but the chronic varieties, which are frequently seen in practice, and which frequently cause great suffering. Vaginitis should always be looked for in such cases, as it is perfectly possible that its existence might escape observation should the practitioner be content with examining into the condition of the os and cervix uteri alone. Other causes of reflex irritation were also mentioned—namely, ulceration or excoriation of the os or cervix uteri, uterine leucorrhœa, and simple hypertrophy of the uterus.

The treatment recommended for vaginitis consisted mainly in the application through a small speculum of a solution of nitrate of silver, varying in strength from ten to thirty grains to the ounce. In cases, however, of extreme irritability of the mucous membrane of the vagina, the employment of Maunders' spray-producer, which throws the solution evenly over every portion of the vagina, was suggested.

A discussion followed, in which Dr. Churchill, Dr. Hardy, Dr. H. Kennedy, and others took part.

Mr. WILSON read a paper

ON THE OPHTHALMIA OF NEW-BORN CHILDREN,

and gave a brief historical sketch, in which he stated the earliest observation on the affection known to him was one by Albrecht, a German physician, in 1690. He also alluded to the writings of Dease, Ryall, Hugh Carmichael, Dr. Evory Kennedy, &c. &c.

The author, after detailing the symptoms and giving a description of the malady, explained the best method of examining infants' and children's eyes, and directed attention to the great danger attendant on an incautious examination. He believed the principal cause of the disease was leucorrhœa or gonorrhœa, but that cold draughts, sudden changes of temperature, and irritating substances might cause it. He did not believe either light or heat could give rise to it.

The chief part of the treatment recommended consisted in great cleanliness and ablutions, changing the patient to a different apartment, in severe cases clipping the chemosis, the application of astringent solutions, and of sulphate of atropia, &c. The author strongly condemned the liquor atropine of the British Pharmacopœia as being exceedingly irritating to the eye, and recommended in its stead the sulphate of atropia, which is soluble in distilled water.

A discussion ensued, in which Drs. Byrne, Cronin, and others took part.

THE SEAT OF THE RESPIRATORY PROCESSES OF COMBUSTION.

By MM. ALFRED ESTOR and CAMILLE SAINT-PIERRE.

M. BERT remarks, that when a warm-blooded animal is submerged, violent agitation of the body occurs, followed by a period of quiescence, with deep inspiratory movements; these diminish, then cease, and the animal, sometimes after a forced expiration, remains motionless. He dates the period of death from the commencement of this last period of quiescence. The sensibility of the animal is soon abolished, but the heart continues to beat for a variable period. The duration of life is scarcely in any way connected with the size of the animal. A rail, about the size of a thrush, retained life for four minutes thirty seconds, whilst immersion for one minute thirteen seconds, on the average, killed pigeons. Wrens, however, died in twenty seconds. Perhaps it may be stated very generally, that small birds are sooner asphyxiated than large ones. Violent movements accelerate death. A fowl, which remained very quiet, lived for four minutes forty seconds, though these birds usually die in three minutes thirty-eight seconds. The withdrawal of blood from the carotid artery or jugular vein of rabbits exercised no notable influence on their power of resisting asphyxia. No difference occurred between fasting and recently fed animals. Wounds and fatigue accelerated death. In an addendum to the preceding paper, M. Bert discusses the question, whether mammals, when plunged in water, draw the fluid into their lungs by aspiration? He gives the results of several experiments, and maintains that little or no water enters during the first period of submersion, when the animal is violently agitated, the glottis being then spasmodically closed; but that when fluid is found in the lungs, the quantity of which is very different in different instances, it enters during the second period, when loss of consciousness has taken place, and the animal makes some involuntary inspirations, the contraction and closure of the glottis sooner or later giving way. Much of the water that gains entrance may be absorbed by the pulmonary veins.

The conclusions at which MM. Estor and St. Pierre arrive are:

1. That the respiratory oxidations take place exclusively in the blood, and are not limited to any particular part of its course, continuing during the whole period of the passage of the blood from the lung till it arrives at the lung again.
2. That they are very active in the arterial system.

3. That the capillaries only augment the venous character of the blood by retarding its course.

4. That the respiratory processes of oxidation are progressive: that in the arterial system they are direct or indirect causes or consequences of reduction, whilst in the capillary and venous systems they are complete, extending to the destruction of the compounds.—*Robins' Journal de l'Anatomie and Brit. and For. Med.-Chir. Review.*

Reviews.

THE ELEMENTS OF PROGNOSIS IN CONSUMPTION; with Indications for the Prevention and Treatment. By JAMES EDWARD POLLOCK, M.D., &c. &c. London: Longman, Green, and Co. 1865. Pp. 423.

THIS volume should have been noticed by us long since, but circumstances prevented our doing so. It is the work of an able and thoughtful physician, and its perusal will well repay even the experienced man. No one can have been long in practice who has not seen or known cases in which grave mistakes in prognosis have been made—that is, the patient, whilst labouring under phthisis, has been pronounced to be in such a state that his life could not last long, and yet, contrary to this deliberate opinion, they have survived not only for months, but even years, thus putting the physician and his practical skill in a very false position, and giving strong grounds to the non-professional public to sneer at medicine in general. We have known cases of this very kind, and it is to guard us against such mistakes that the present volume has been written, and it differs from any other work we have seen in the very elaborate way in which the subject is treated, for to each and all the several points discussed a separate chapter is given; thus the different stages of phthisis are discussed *seriatim*, and at great length, as also the many points which are known to influence the progress of the disease, such as age, sex, temperament, &c., and also the numerous complications, as they may be called, any one of which is capable of modifying, and in a very marked degree, the course, and above all, the derivation of phthisis. Several of the chapters, too, are illustrated by cases, detailed with great accuracy, and many under observation for years. We need scarcely observe that cases of this kind are of great value, as showing the changes in the physical signs from year to year, and so teaching us the natural history, as it were, of the disease. Nor are such cases easy to be observed. They need to be always carefully examined and noted at the time, and numerous circumstances tend to make us lose sight of them before their course is ended, and thus the many cases we have detailed in this volume are of the more value.

Nor has the author forgotten to avail himself of the assistance to be derived from statistics, for in each chapter we find numbers brought to elucidate the particular point under discussion, and when we recollect that he is attached to an hospital devoted solely to the treatment of phthisis, we can easily understand their value. We believe that statistics can aid every point connected with disease, except the treatment, and that a grave error has been committed by those who have attempted to regulate our practice by numbers. It has done much harm, and we might almost say that medicine has retrograded since statistics have come into vogue. Be this as it may, the chapters in this work in which they are introduced are most practical, whilst the numbers are so large as to give almost a certainty to the many questions discussed. We might, as an example, direct attention to the chapter on "Clubbing of the Nails," to which the author has given much observation; but we must refer our readers to the work itself for the details. And, again, in the chapter on "Age, as a modifier of the Course and Duration of

Phthisis," will be found many important observations having a high practical value; but, in truth, all the chapters of the work are so valuable that we would be unable to notice them *seriatim*. There is, however, one chapter to which we must take exception—that in which the author speaks of gout and rheumatism in connexion with phthisis. He thinks that the latter especially is closely allied to phthisis, and gives a table of 142 cases, of which 49 had rheumatism before the phthisis showed itself. What form of rheumatism is not stated; but it does not accord with our experience in Dublin—we mean this connexion between rheumatism and phthisis. We believe, however, that rheumatism, especially of the acute form, is a much more common disease in London than Dublin, and this may in a certain degree be a cause of the difference. As to gout in union with phthisis, it must be very rare indeed. For ourselves, we look upon the two diseases as antagonistic, the one to the other. We believe if gout have declared itself that the chance of phthisis ensuing must be very rare; and, on the other hand, we have never seen an instance where gout declared itself in the course of phthisis; but gout, like acute rheumatism, is more common in London than with us in Dublin, and so the difference in our views may in part be explained.

In addition to the more usual symptoms of phthisis, and into all of which the author enters at length, we have also chapters devoted to the consideration of gastric symptoms, diarrhœa, fistula, &c. &c., as modifying the progress of the disease, and very valuable chapters these are.

The work concludes with several chapters devoted to the subject of treatment, arranged according to the stages, &c., of the disease, as also some valuable remarks on the prevention of the affection. We can heartily recommend the entire work to the notice of our readers.

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 25, 1866.

STATE VACCINATION.

It may be received as an axiom, that in order to make vaccination effectual in the eradication of small-pox, it ought to be universal, because if only a few persons are unprotected, they may receive the variolous infection and become the means of spreading the disease through the community. The data relating to the conditions under which the spread of small-pox may be arrested or encouraged, are now so well established as almost to deserve the name of scientific laws; and if a few persons are still found so ignorant or so prejudiced as to deny the value of vaccination as a preventive agent, they really deserve no more serious attention than those who would dispute the facts proving the rotundity of the globe or the principles of gravitation. The only objection to the performance of the operation of vaccination which deserves even a moment's consideration is founded upon the circumstance, that in a few cases out of many thousands or millions, children have exhibited on their bodies the marks of other cutaneous diseases besides those of vaccinia; but as it has been very truly explained, it is most probable that in such instances vaccination has only called into active existence a latent pre-

disposition which required some slight excitement for its development. The transmission of syphilitic disease by Vaccination, if it be really well authenticated, is at any rate a most rare occurrence, and the only wonder is, considering the great number of syphilitic children in existence, and the excusable ignorance of the fact in some cases on the part of the public vaccinators, that such cases do not occur. We do not, of course, deny that syphilis may be inoculated, and we have read of a few instances in France in which it appears that by some accident a syphilitic pustule was caused by vaccination, but the extreme rarity of such a circumstance (if, indeed, as we before observed, it ever occurred) really proves the general efficacy and safety of vaccination.

We regret to find that on the Select Committee appointed to consider the provisions of the New Vaccination Bill there is not one person, so far as we are aware, who practically understands the subject, and we can only hope that the Committee will avail themselves of the advice and assistance of those who do, and will turn a deaf ear to the wiseacres who pretend to a degree of knowledge they do not possess, and who make assertions the more recklessly as their ignorance is the more profound.

We wish that it were in our power to persuade the Legislature to remove the contract of vaccination altogether out of the hands of the Poor-law Board and their satellites, the local Guardians, all of whom are utterly incompetent to deal with or even understand the questions which must often arise in reference to the efficient performance of vaccination. What would be thought of a law which placed the regulation of the Navy in the hands of clergymen, or the affairs of the Church in the hands of the Horse Guards? And what earthly connexion can be proved to exist between the Poor-law Board and the performance of a sanitary operation intended for the prevention of disease? So far from there being a single reason for entrusting the superintendence of vaccination to the Poor-law Board there are a host of reasons against it. This Board has shown itself, and confessed itself, utterly incompetent to deal with the treatment of disease in the Workhouses, and what steps has it ever taken for the prevention of disease? Again, what necessary relation is there between pauperism and vaccination? It is absolutely essential that the very idea of pauperism should be banished from the minds of those who avail themselves of the services of the public vaccinator, and although the recipient of the benefit may be unable to pay a private medical man for the operation, he ought to understand distinctly that the acceptance of the favour involves no feeling of degradation. Vaccination is simply a public duty incumbent on the State and on individuals, and should be regarded in the same light as the franchise or any other institution sanctioned by the laws of the land.

The superintendence of vaccination should unques-

tionably be undertaken by the Government of a country, and the operation itself ought to be compulsory. In order to make it efficient, punishments must be not only devised but enforced in the case of those who refuse to submit to the law, and there is no more interference with the liberty of the subject involved in such a course than in punishing a man for doing any act injurious to the public health, or for evading the payment of a legalized impost. The Government of a free country does not hesitate to confiscate a man's goods, or to seize his person if he neglects or refuses to pay the taxes, and we cannot see why a man is to be allowed, without any punishment, to propagate a disease of a fatal and dangerous nature, by his obstinacy or his neglect.

We consider the whole system of vaccination in this country so unsatisfactory, and the remedies proposed in the recent Government Bill so inadequate to meet the existing evils, that we are not sorry at the delay of the measure. In the first place, as we have remarked, the Poor-law Boards ought to be entirely relieved from a duty which they are incompetent to discharge. They are disqualified by their ignorance of the whole subject of vaccination, although this ignorance is not culpable; but they are also disqualified by their inherent meanness and their love of jobbery, which prevent them from dealing with any matter involving scientific questions in a broad and comprehensive spirit.

Another great and palpable defect in all the arrangements made to promote universal vaccination is the want of inspectors to ascertain whether the operation is adequately performed, and whether the vaccinators are diligent and punctual in the discharge of their duties. All that the Poor-law Guardians do at present is to fix the rate of remuneration, and to appoint the vaccinators, and then to leave things to take their own course. The Boards receive the returns sent in from the different districts, but they take no pains to ascertain whether they are correct, and whether vaccination is carried out in the most efficient manner.

We desire in this place to express our decided opinion that no efficient system of vaccination can be adopted which does not involve the performance of the operation from arm to arm. We do not deny that in very many cases, dried or preserved lymph may be used with very great advantage and with perfect success; but we maintain that in order to keep up an adequate supply of lymph, and to ensure, as far as possible, from year to year, a thorough system of successful vaccination, it is necessary to vaccinate from arm to arm at regular and stated periods. We are writing from a practical knowledge of the subject, and we know the frequent disappointments and failures which occur from using preserved lymph, and which may almost certainly be obviated by operating from one subject to another.

Holding these opinions, we are also decidedly favourable to the appointment of only a limited number of vaccinators in each district, as it is only by keeping up

a regular series of vaccination cases from week to week that success can be uniformly secured. We are aware that many members of the profession think that every qualified medical man ought to be appointed a public vaccinator; but we regard this view of the case as a mistaken one. The remuneration for the operation (even if it were considerably augmented) could never compensate a practitioner who had only a limited number of cases in the year, while, on the other hand, it might fairly pay another whose cases were numbered by hundreds. To put the matter in what logicians call the concrete form, we consider a fee of half a guinea to a guinea quite little enough for an isolated case requiring in the first place a careful selection of a healthy arm at the due period of the maturation of the vesicle; next, the operation itself; then the necessary visits to ascertain the progress of the case; and the management of any collateral symptoms that may present themselves. But such a sum as that we have mentioned can hardly be expected, and cannot fairly be claimed by those who vaccinate children by the hundred, and whose trouble in attending a dozen cases is not much more than a private practitioner would have with a single case. It is also on many accounts desirable that a succession of children should be brought from week to week to some central spot, and the numbers thus operated upon would fulfil the double object of perpetuating the due supply of lymph and of remunerating the vaccinator.

As our remarks, however, are read not only by our brethren who dwell in cities and large towns, but also by those who are placed in wide and badly peopled districts, we are aware that the above remarks cannot have a universal application. In the highlands and islands of Scotland, for instance, vaccination can be performed often only on isolated cases; but notwithstanding the difficulty and trouble which must devolve upon the vaccinators, we are happy to learn that in this part of the British Empire vaccination is very efficiently carried out. The special reasons of this efficiency were ably pointed out by one of our correspondents in our last week's impression.

THE FELLOWSHIP OF THE ROYAL COLLEGE OF SURGEONS.

IN opening our columns to the discussion of this question, and in the observations with which we started the discussion, we fully anticipated the course of the controversy, and we courted the inquiry for the purpose of eliciting the opinions of the profession in Ireland, and putting the Council of the Royal College of Surgeons in possession of the feelings of those most interested in the matter. Now that the effervescence of our correspondents has passed off, there appear various vested interests and contra arguments which cannot be adjusted without patience. We have in the field the old Licentiates, represented by Dr. BEWLEY and "A Militia Surgeon," who advocate their right to the Fellowship without examination, and we have the Fellows by examination whose

views are enunciated by Dr. HADDEN and "L.R.C.S.I.," upholding the special examination as the *sine qua non* for admission to the Corporate Body of the College. Thirdly, we have the gentlemen who hold extra collegiate qualifications, and think that they should be admitted to the Fellowship of the College by a year of grace without other restriction than a fee, the lower the better.

Each of these classes are sturdy in the defence of what they consider their rights, and fly to arms without sufficiently regarding the compatibility of their interests, and we refer them to a closer perusal of our own remarks in THE PRESS AND CIRCULAR for Feb. 7, for an antidote to any feelings of antagonism which they may experience. The Fellows of the College are very reasonably alarmed at a very unreasonable assumption, if they conceive that there is any probability of an indiscriminate opening to the rank which they enjoy. No such course has been thought of, nor, we believe, would the Council tolerate such a proposal without the unanimous assent of the Fellows. Practitioners holding other qualifications must regard their admission to the College strictly as a favour not as a right, and years of grace, are, as we think, an abuse of corporate privileges which, if tolerated at all, should be as a matter of expediency under some extraordinary circumstances. But the co-option of gentlemen already holding the diploma of the College—well tried and of high character—is a different case, and we cannot think that the Fellowship of the College would be degraded by their admission.

It is manifest that the Fellowship examination serves no good purpose. It does not protect the existing Fellows from association with ineligible persons, and it certainly excludes seventy-five per cent. of the class who it should be desired to attract to the College.

We repeat our former opinions:—

"The College should require in its Fellows social as well as professional position—education and experience for the dignified discharge of their duties, and without which their opinions can carry no weight—and unimpeachable honour and respectability to disarm suspicion of interested motives. For the possession of these qualities the present bye-law provides no security, and yet it interposes conditions which practically disbar the very men who possess them, and whom it would be most desirable to identify with the College. We neither hold that a newly-fledged Licentiate with ten guineas in his pocket and a knowledge of comparative anatomy, hot from the army examination, should be necessarily admitted, nor that a surgeon of perhaps thirty years' practical experience, but grown rusty in his "ologies," should be rejected, and any regulation which renders either course compulsory operates to the disadvantage of the College."

The proposal which we have put forward appears to us reasonable. Let young men, who are as yet untried by professional intercourse with their fellows and with the public, continue as they have done to win for themselves the first rank in their profession by examination; and let them sustain their right to consideration by giving proof of their talent and their assiduity. But let not men who have given as good security for the possession of such qualities by years of practical trial be refused

admission because they cannot enter by the same portal as their younger brethren. In a word, let us have in every case, good evidence of professional, moral, and social rank; and when such qualities exist, we are convinced the Fellows of the Royal College of Surgeons will waive their vested right in their earnest wish for the good of their College and in justice to their profession.

HOW SCOTCH PRISONERS ARE FED.

It is a common idea that in Scotland our prisoners are too leniently dealt with, and that their diet is both too good and abundant. And many people are of opinion that if the daily fare were restricted to articles of the plainest and coarsest kind, given in the scantiest measure consistent with the maintenance of life, our jails would be less crowded by those who care little for the restraints of imprisonment so long as they are provided with food and shelter. But they who entertain such ideas seem to forget that while the laws of our country provide for the punishment of crime, and the infliction of a just retribution on offenders, there is a higher rule which provides for the preservation of the health of our fellow-creatures, and whose enactments cannot be disregarded with impunity. It is the duty, therefore, of those in authority to see to it, that while they debar the criminal from everything in the way of diet which might be accounted superfluous or luxurious, they must at the same time furnish him with food in such quantity and quality as the requirements of health demand. In order to arrive at safe and satisfactory conclusions in regard to the best dietary scale for Scotch prisoners, an investigation was instituted some time ago, and the results of that inquiry have just been made public in a report on the prison dietaries in Scotland, printed by authority of the managers appointed under the Prisons Administration Act of 1860. The Commissioners furnish us with much information of a very interesting and important character, and the conclusions they have come to appear to be drawn with the greatest precision and care. The fact, that all the prisons in this country, the local prisons as well as the general prison for Scotland, are under one code of rules with respect to diet, has greatly facilitated their labours, and renders their deductions more reliable and correct.

The distinctive feature in our Scottish dietary tables, as compared with those of England and other countries, consists in the prominence given to certain articles of food—viz., oatmeal and milk, and we are glad to see that the Commissioners agree in their opinion as to the nutritive value and cheapness of this national dish. It has often been a subject of wonder, especially to Englishmen, how our farm servants are so hardy and healthy, and so capable of enduring continued labour, on what they consider such poor fare as porridge and milk; but they forget that modern scientific research has proved that milk and oatmeal provide an

amount of nutriment at least equal and generally superior to that furnished by the diet of the majority of English labourers. And what is good for farm servants and labourers must of necessity be good for prisoners. But it is chiefly to an abundant supply of milk that the Commissioners attach special importance, and they believe that it is this that lies at the foundation of the success of the dietaries in present use. In most districts of Scotland a good supply of milk can almost always be obtained, and the Report says that it is now found that when a prisoner begins to droop and fail in health, a small extra allowance of this article sets him up better than anything else; and it further states that at one time the withdrawal of milk from the dietary was attended with serious mischief and extensive epidemic disease. Then, again, it has been found that in all cases of short-sentenced prisoners the use of milk enables the authorities to dispense with the expensive article of butcher meat, and this must prove a considerable saving to the country. With regard to the effects of the diet at present in use in the prisons of Scotland on the health of the prisoners, this Report yields the most satisfactory information, and we find that the diseases which previously prevailed on account of defective nutrition have during the past ten years entirely disappeared. The amount of sickness, too, has been reduced from 65 to 45 per cent., and the death-rate, notwithstanding the substitution of long imprisonment for transportation, has fallen from 1.41 to 1.15 per cent., while the number of diseases contracted after admission to prisons has also decreased from 27 to 15 per cent. Such results are most gratifying, and reflect the greatest credit on the wisdom and sound judgment of those who framed the scale of diet now in use.

The Commissioners bring out another important point which distinguishes the Scottish system as contrasted with that of England as regards the quantity and the cost of provisions. They find that the same amount of nutritive food is furnished in Scotland at much less expense than in England; while in the Scotch convict dietaries the probationary class have 18 oz. more real nutriment at less cost than the English convicts of the same class.

While expressing their approval generally of the system of diet at present in use, the Commissioners, after very careful and full consideration of the subject, have felt it their duty to suggest some alterations, and they propose that the following reductions should be made:—In the local and county prisons it appears that the food supplied to each prisoner is adequate generally for males, and more than adequate therefore for females and juveniles under fourteen years of age. While making no change in regard to the diet of the men, they propose to reduce the amount of food furnished to women and children, and we think this alteration is proper and judicious. Then in the general prison at Perth it is proposed to reduce the quantity of butcher meat supplied to female convicts in the reformatory classes, as well as

the amount of oatmeal porridge on three days of the week; cheese, however, is to be added, to the extent of $4\frac{1}{2}$ oz. weekly. This change is founded upon the surplus returns of the food supplied on the days specified in the Report, and if carried out, will effect a saving of about £250 a year in the general prison alone.

In a few of the prisons it is found that milk cannot be got in sufficient quantity, and treacle-water is substituted; but it is found that under this fluid prisoners lose flesh and weight. The Commissioners, therefore, recommend that when milk cannot be procured, 4 oz. of cheese, or an addition of 6 oz. of oxheads, should be made to the broth or soup daily.

It is curious to observe from the Report that in some local prisons potatoes, which are well known to possess antiscorbutic properties, are never given, the only reason being that the cooking of them gives too much trouble. This is a paltry excuse, and the Commission advises that this vegetable should be given in all prisons during the potato season. Upon the whole, a perusal of the interesting information collected by the Prison authorities shows that at the present time the dietary of Scotch prisons is in a most satisfactory state, and as near perfection as could possibly be desired. It is proved by this enquiry that the system followed in this county is attended by the most beneficial results as regards the health of the criminals, and that it is also a more economical one than that acted on in England. Such an investigation is of great importance, and the results, as ascertained by the Commissioners from the most precise and accurate data, show that the scale of diet allowed to our prisoners is both scientifically and practically correct.

CLINICAL LECTURES.

We publish to-day an important and valuable lecture on "Fever," delivered by Sir Dominic J. Corrigan, Physician to the Queen in Ireland, introductory to a Fever Clinic, which is about to be delivered in the Richmond Hospital. This lecture, from the pen of the first authority in Ireland on fever, will be followed by essays on the same subject by Dr. R. W. Lyons, Physician to the Whitworth Hospital; Dr. Gordon, Physician to the Richmond Hospital; Dr. Banks, Professor of Practice of Medicine; and Dr. McDowel, Professor of Anatomy and Physiology in the University of Dublin. We hope to publish this valuable series of lectures as they are delivered.

We have also in type a communication from Dr. Duncan, Physician to the Adelaide Hospital, on "Gout," which we are compelled to postpone till our next issue, and we hope to publish shortly a series of essays on Clinical Surgery by John Hamilton, F.R.C.S.I., Dr. Geoghegan, and Dr. Hayden.

We are enabled to give to-day a communication from Mr. Barwell of the Charing-cross Hospital on "Distortion of the Hand," which we hope will be shortly supplemented by communications from Mr. Gascoyne.

Notes on Current Topics.

THE ARMY AND NAVY MEDICAL OFFICERS.

It will be recollected that we warned our Military Medical brethren, especially those of the Army, a few weeks ago not to be too sanguine that all the Recommendations of the Select Committee lately appointed to report on the pay, rank, retirement, &c., of Army and Navy Medical Officers, will certainly be adopted. We also expressed our opinion that in all probability the concessions would be made in the case of the Navy, but that it would be necessary to make a new estimate of expenses to the House of Commons. Our predictions have so far been fulfilled, for we learn that the recommendations of the Committee will be acted upon by the Admiralty, and that a supplemental estimate, necessitated by the proposed augmentation of pay, will be submitted to the House of Commons. No intimation has yet been given of the decision of the authorities at the Horse Guards, at which, after the doubts we expressed, we are not surprised. The Council of the College of Surgeons of England, however, in anticipation that the whole of the recommendations will be carried out, passed the following resolution at their last meeting:—

"That the Council, in acknowledging the receipt from the Secretary to the Admiralty of the report of the Committee appointed to inquire into the whole question of the rank, pay, and position of the Medical Officers of the Army and Navy, beg to express to the Lords Commissioners of the Admiralty, the Secretary of State for War, and his Royal Highness Commanding-in-Chief, their cordial concurrence in the recommendations contained in that report, and their belief that those recommendations, if fully carried out, will obviate the objections at present felt to entering the Medical Service of the Army and Navy.

"That the Council further desire to express their opinion that the adoption of these recommendations will induce a better educated class of medical candidates to seek admission into these services than hitherto, and will thereby tend to promote the health and efficiency of her Majesty's Military and Naval forces."

It may be premature to assume the certainty of adoption of all the Recommendations of the Commission, but if they should become the basis of future arrangements, we think the claims of the profession will have been liberally and honourably met. Nothing is more powerful in the furtherance of the demands of the profession than strict moderation, nor can there be any course more injudicious than to ask for what is manifestly unreasonable, or to show dissatisfaction with just and equitable concessions. We cannot think that Army Medical Officers as a class have, under the Recommendations of the Commission, cause for grumbling, and we shall regret if the advances of the War authorities towards a reconciliation with the profession be met in an ungenerous or over-fastidious spirit.

THE ANATOMICAL MUSEUM "NUISANCE."

ANOTHER case illustrating the frauds inflicted upon the unwary portion of the public is reported in our legal intelligence of the present week. The plaintiff was a farm labourer, and the defendant is said to be the proprietor of an Anatomical Museum in Oxford-street. The story is an old one, and by changing the names, it might be regarded only as a reprint of many another transaction of a similar character. The victim enters the museum, he imagines that he is ill, he is persuaded to pay guinea after guinea, or

rather to give round sums varying according to the rapacity of the quack and the length of the countryman's purse, and the result is that instead of an imaginary disease being cured, a real one is established. In the present case it appears that the miserable "patient" was violently salivated by corrosive sublimate, although his illness, if he had any, was a very slight one. No defence was made to the action, and the jury gave damages to the extent of £60. As far as the bare justice of the matter goes, perhaps in this instance, the result is satisfactory, but why, we emphatically ask, are these museums and their accompanying knaveries allowed to exist in the heart of the metropolis, which does not allow the small dealers in indecency to escape without punishment? It must be recollected that a person holding himself out as a qualified medical man at one of these filthy dens is never interfered with by the law, and it is only when some victim has the commendable boldness to come forward and bring an action, that the whole system of fraud and iniquity is unmasked. Surely this case shows the utter inefficacy of the Medical Act as it at present stands, and the urgent need of some further legislation.

THE POOR-LAW BOARD AND THE WORKHOUSES.

In answer to a deputation which lately waited upon the President of the Poor-law Board to convey to him the resolutions passed at the public meeting in Willis's Rooms, that functionary announced that the Board was about to make an inquiry into the alleged imperfections of the Metropolitan Workhouses as receptacles for the sick poor. Now, if the workhouses were like the prisons in the time of John Howard, or like some of the lunatic asylums at the beginning of the present century, without any national control or supervision, the statement could be received with satisfaction. But the Poor-law Board knows all the facts already, as it is invested with an absolute and irresistible power to visit all work houses and to report upon their condition; and it has made use of its power, and possesses abundance of reports as to the inefficiency of the arrangements. It is perfectly true that there are certain parishes within the Metropolitan District which are not yet strictly under the immediate control of the Board, but are governed by local acts; still they are all practically under the government of the Board, which visits them all, and could enforce its regulations upon all, if it thought proper to do so. But we deliberately affirm that until a very recent period the Board has actually shielded the local Boards, even when it knew that they were open to the severest censure, and that with full and ample knowledge of abuses and defects it has refused even to institute investigation. The Poor-law Board has systematically neglected the interests of the sick poor, and has most cruelly ill-treated the Poor-law Medical Officers, who are the only friends to the patients. Mr. Rogers of the Strand Union, very justly observed at the recent deputation that the inquiries instituted by the Board were inefficient; but he also observed that he spoke in jeopardy of his position. In truth, the Medical Officers dare not speak out, under fear of dismissal; and the Poor-law Board, with a truckling and cowardly policy, which does them infinite discredit, would willingly allow a medical man who fearlessly did his duty, to be sacrificed, or perhaps ruined, by the local Guardians. We have no confidence in the so-called "inquiry" to be instituted by Mr. Farnall

and Dr. Smith. The former has almost always made some subordinate person a scapegoat; and as to the latter, whatever may be his talents (and they are considerable) and his firmness of purpose, now that he is tasting the sweets of office he will probably fall in with the miserable policy hitherto pursued by the Board. We hope that our predictions may not be realized; but when the Poor-law Board offers us any benefits we may say, *Timeo Danaos et dona ferentes.*

TRANSMISSION OF SENSE AND VOLITION.

On Friday last M. Emile du Bois Raymond delivered a lecture on this interesting and apparently unfathomable subject at the Royal Institution, and performed a number of very remarkable experiments in demonstration of his views. M. Raymond likened the nerve system to a series of telegraph wires, the transmitting agent being, however, different from electricity in being arrested by a ligature on the nerve. He showed that the transmission of sense was not by any means instantaneous, for the eye could not estimate any less interval than about the tenth of a second. The instrument by which M. Raymond calculated the velocity of transmission of electricity through nerves consisted in a lever attached to the extremity of a fixed muscle in such a way that the moment the muscle contracted the current was arrested. The following table of velocity was exhibited:—

	Millimètres in one second.
Electricity	464,000,000
Light	300,000,000
Sound in iron	3485
" water	1435
" air	332
Cannon-ball	552
Wind	1—20
Eagle's flight	35
Greyhound or racehorse	25
Nervous agents	26—30
In throwing a stone 24 in. high	21·9
Muscular contraction	·8 = 1·2
Arterial wave	9·25

POISONING BY WATER-HEMLOCK.

DR. LENDER relates a case in which three boys ate of the roots of water-hemlock. In one vomiting set in, by which further symptoms were prevented. The second, who had eaten but little, vomited after some time, and became faint and unconscious, but had no very severe symptoms. The third, who had eaten most, vomited in about an hour; he became insensible and convulsed generally; his respiration became stertorous, and water, tinged with blood, flowed involuntarily from his mouth. Death followed, about three hours after the first appearance of the symptoms. At the post-mortem examination the vessels of the brain were found to be remarkably full of blood; there was about an ounce and a half of bloody serum in the pleuræ, and a singular effusion in the pericardium. The costal pleura was injected of a bright red colour; the lungs were hyperæmic, and the trachea and bronchial tubes were injected, of a bright red, and contained reddish mucus. The mucous membrane of the stomach and duodenum was of a dirty dark-red colour, but with spots of injection; the liver, spleen, kidneys and pancreas, were hyperæmic.—*Vierteljahrsschr. für Gerichtl. Med. and Brit. and For. Med.-Chir. Review.*

A SEPARATE department has been formed for the transaction of business relating to the cattle plague. Communications on the subject to be addressed to Colonel Harness, R.E., C.B., Cattle-plague Department, 7, Westminster Chambers, Victoria-street, S.W.

Correspondence.

✂ We are not to be assumed to agree with the views of our Correspondents whose communications we insert for the purpose of affording opportunity for the enunciation of all shades of opinion in things medical. Our revision of letters is, therefore, confined to the removal of statements or expressions which we consider unsuitable or irrelevant to the subject in hand.

POOR-LAW MEDICAL REFORM AND VACCINATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Permit me through the medium of your columns to say a few words on the subject of the Vaccination Bill, which most of your readers are now aware has been referred to a Select Committee of the House of Commons. A Member of Parliament, in writing to me on the subject, said, "By this morning's papers you will see the fate of the Vaccination Bill, which had not a single friend in the House." Yet this very Bill had passed a second reading without a single word being said against it, proving most incontestably that the check given to a Minister of the Crown is due to our profession, and in no small degree to our Association, which, so far as I know, was the only body that sent a pamphlet on the subject to each Member of Parliament. I have written to the Select Committee requesting to be allowed to give evidence, and I trust other gentlemen will do likewise.—I am, &c.

RICHARD GRIFFIN.

THE IRISH COLLEGE OF SURGEONS—THE CASE OF THE OLD LICENTIATES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is by no means surprising to an oldster like me to find that your comparatively juvenile correspondents, Dr. Hadden and "L.R.C.S.I.," should attach an overweening degree of importance to the dignity of the Fellowship of the College of Surgeons in Ireland. Constituted as the College now is, there is, doubtless, a very marked difference between the rank of a Fellow and of a Licentiate who has obtained his diploma subsequent to the year 1844. Since the period when the Government unfortunately deemed it expedient to authorize the College to confer its license on men *not qualified by education or knowledge* to be Fellows, it is perfectly intelligible that modern Licentiates should experience a mortifying consciousness of inferiority, social as well as professional, when they compare their position with that of their more fortunate brethren; and therefore it is no wonder that spirited and sensitive men, as Dr. Hadden and "L.R.C.S.I." appear to be, should indignantly repudiate "the sale of Fellowships," or that the latter should impetuously exclaim, "I would not hesitate one moment to pay even forty or fifty pounds for the Fellowship, provided I was certain it will never altogether become a question of £ s. d." Under existing circumstances, this is a most commendable exhibition of wounded pride. "L.R.C.S.I." being probably a man of superior acquirements, and aware that "a strict and searching examination" would prove his indubitable right to the lofty honours of a Fellowship, naturally feels his position as a Licentiate to be both galling and derogatory, and perhaps is even convinced that worth should make the Fellow.

But your correspondents are, in my opinion, altogether in error as to the reason why so inconsiderable a number of the

old Licentiates should have sought for or accepted the Fellowship of the College. To explain the true cause intelligibly, it will be necessary to refer to the history of the change which took place in the constitution of the College in 1844, and this I shall endeavour to do as briefly as possible.

Before that year the College consisted of "Members" and "Licentiates," the former being the governing body—in an executive as well as in a legislative capacity—there being no "Council" in those days. No candidate for "Letters Testimonial" was admitted to the *license* of the College unless he were qualified for the *Membership* also; and this qualification was duly recorded on the face of every diploma, no further examination being deemed necessary. Herein consisted the grand distinction between the old system and the new. The public had full assurance that nobody obtained the sanction of the College to practise as a Surgeon until he had satisfied a Board of Examiners, composed of the *élite* of the profession, that he was fully qualified for the highest position which the College could bestow. And to this fine old system is to be attributed, *me judice*, the high degree of estimation in which the College was held for so many years. Under the same fine old system Ireland could boast of such contemporary men as Colles, Crampton, Cusack, Wilmot, Jacob, Carmichael, Peile, Read, Kirby, Porter, and a host of other stars of almost equal brilliancy; whilst the humblest Licentiate honestly believed (and not without reason) that he was a scion of the most respectable Medical Corporation in the world. Then came the fatal blunders of 1844. "The sale of Fellowships," as your correspondents designate the transaction, was one of those blunders—sad and humiliating enough, no doubt, though it had some redeeming features too. But time, *edax rerum*, has well nigh obliterated the evil consequences of this step in the wrong direction; and so I pass it by for the present, merely reiterating my conviction that it was by no means the principal cause of the notorious disinclination of the old Licentiates to countenance the proffered Fellowships. The real cause lay deeper—namely, in the deterioration, if not in the destruction, of the high character of the College itself, coupled with a certain personal slight, to which I shall presently allude.

I have said that under the old system the College consisted of Members and Licentiates, and that no man could become a *Licentiate* until he had proved himself, by education and examination, fully qualified to be a *Member*. By the constitution of 1844 the designation of "Member" was abolished, and that of "Fellow" substituted in its place, whilst the designation of "Licentiate" was retained unaltered. This was a far more serious blunder than the "sale of Fellowships." If the pristine relation of the two ranks had been retained—that is, if there had been a single and uniform qualification for Fellows and Licentiates, little mischief would have been done. But when it was announced that for the future there were to be *two* distinct classes of Surgeons turned out of the Examination Hall—one a superior article, the Fellow; and the other an inferior article, the Licentiate—all the pride of the old Licentiates in their College became a thing of the past, like an unpleasant dream. Ichabod! the *prestige* of the College was gone, its glory had departed, and its most devoted sons were covered with shame and confusion of face.

I may be told that this was a case in which the *public* was the aggrieved party, seeing that the confidence of the public in the College was abused by the grant of its license to persons *not fully qualified*. Unquestionably the public had abundant reason to complain if it understood the merits of the question. Unhappily, however, the public has always been content to remain profoundly ignorant of medical affairs that do not immediately concern its own interests, and accordingly on this occasion it was silent and submissive

Again, it may be objected, granting that this fundamental change in the constitution of the College was injurious, and calculated to weaken, or even to destroy, the interest felt in its reputation by the old Licentiates, surely the old *Members* were equally aggrieved. Not *equally* by any means, though I have reason to know that many of the most distinguished men in the profession highly disapproved of the change, and keenly felt the injury which the character of their College had sustained. Others may have been partially reconciled to the new *regime* by the somewhat selfish consideration that their *status* in the College was unaltered, inasmuch as "Members," by a mere stroke of the pen, were converted into "Fellows." Some may have been tickled by the new title, and have fancied themselves on a par with Fellows of T.C.D.; and others, again, of a strong anti-democratic tendency, may have approved of the measure, especially as it afforded them a prospect of a seat in the new governing body, the Council. Be that as it may—and even allowing that the *sentimental* grievance was equal as regards both classes—there was a *personal* grievance, which peculiarly affected, and still affects, the old Licentiates, or perhaps I should say the remnant of them, for many have gone to their rest.

The College of Surgeons, by the charter of 1844, virtually pronounces its new Licentiates to be what I have termed, for want of a better phrase, an inferior article; and I am guilty of no disrespect in recording a patent fact. I cheerfully admit that many of these gentlemen are as liberally educated, and as fully competent to practise their profession, as many of the Fellows—the superior article; still it is a fact that the College has placed upon them the stamp of inferiority. Their acceptance of the position is, I willingly acknowledge, no affair of mine; and I urge no objection against that which may have been a matter of necessity as well as a subject for regret. But I do object to a personal slight offered by the College authorities to the old Licentiates in placing their names in the same list with those of the new creation, thereby leading the public (as well as the uninformed portion of the profession) to infer that the men who, by the solemn act of the College, have been declared *equal*—as far as education and knowledge are concerned—to the Fellows (or Members), are in reality only fit to be classified with those whom the same College (would that it were in truth the same!) declares to be *inferior*. I cannot believe that this slight was designed as a deliberate affront to the old Licentiates, or that it was perpetrated with the sordid view of inducing them to pay the price of a Fellowship. It may have been merely an oversight; in charity, let us suppose this to have been the case. But even with this charitable supposition, it was not, and is not, pleasant to the old Licentiates to discover that their interests should be overlooked and their feelings disregarded. The oversight—if oversight we must call it—was, I firmly believe, the means of severing the last link of affection which bound the old Licentiates to the College of their choice. Owing, in a great degree, to this sense of alienation, many of the old Licentiates—I believe a vast majority—have provided themselves with diplomas from other medical bodies; and when in 1859 the King and Queen's College of Physicians admitted to examination the Licentiates of the Irish College of Surgeons, with others, at a reduced fee, the opportunity of acquiring an additional and (as it was believed) a more creditable qualification, was eagerly seized by a considerable number of the survivors of those who had been sufferers by the fatality of 1844.

Your correspondents, Dr. Hadden and "L.R.C.S.I.," must have been ignorant of all these details, or they could not have contemplated the project of requiring the old Licentiates (previous to 1844) to undergo another examination in the event of their seeking the Fellowship of the College.

This is a contingency, however, which is hardly likely to arise, for the reasons stated above.

If I am correct in the opinions which, as an "old Licentiate" of more than five-and-thirty years' standing, I have ventured to offer on the present constitution of the College of Surgeons, it only remains to devise a plan by which the former high position of the College may, in some degree, be restored. But this is a task which I must leave to wiser and younger heads than mine. Perhaps a step in the right direction might be taken by reviving the practice of a uniform examination for Fellows and Licentiates, letting the public clearly understand that no candidate shall obtain the diploma of the College until he has proved by a sufficient examination that he is qualified for the Fellowship. This reform should, of course, be supplemented by the restoration of election to the Fellowship, the Fellows to retain the privilege of appointing the Council and other officials of the College. As to the possibility of reclaiming the residue of the old Licentiates I am not very sanguine, nor is it a matter of much consequence, as in a few short years the last of them will have passed away. Certainly, the bait of the Fellowship for twenty pounds (as suggested by one of your correspondents), even without the formality of an examination, will not have the effect of catching them. The same offer was made for half the sum in 1844, and the abortive result is now a matter of history.—I have the honour to be, Sir, your obedient servant,

ED. BEWLEY.

Edington, Clara, 14th April, 1866.

THE ARMY MEDICAL SERVICE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—I beg to enclose you an extract from a letter received from a friend of mine, who is a Staff-Surgeon, and should you deem it worthy of a place in your columns, you will oblige me by inserting it in your next issue. I have three sons, and am in a position to educate them and give them their choice of a profession. I always looked forward with pleasure to the hope that they would adopt the Army Medical Department; but I must confess that I am so disgusted with the service, from the truthful picture here portrayed, that my ideas are completely revolutionized. I trust that it may be a warning to youthful aspirants for army medical honours, until a better state of things exist in that important arm of her Majesty's service.—Faithfully yours,

AN M.D. AND J.P.

April 19th, 1866.

P.S.—The letter contains far more painful details, but I suppress them, from a feeling that their exposure would be *humiliating to the profession*.

"I am glad to see the profession (civil) are making a move to improve their social standing, by improving their course of education, &c. I do not know what they (the authorities) are to do about us; they must make it much more remunerative, and remove even the shade of objectionable regulations, to keep good men. It is a good school for a youngster for a few years, if he gets a good station, *but no career*. It is bad pay for a poor man; and a rich one is a fool if he stays in it, to spend his time in Bermuda, Barbadoes, Singapore, China, or India. The good stations are rapidly disappearing; and when none but tropical remain, a man had better go in for the Indian service altogether. If we had quarters fit for a married man to live in, or even lodging allowances, pecuniary allowances, or commutation for allowances in kind, as the Americans have, it would not be so bad; but as it is, it is a hard and generally unsuccessful struggle for existence. Apparent luxuries are heaped on you, and necessities denied. I, for instance, as a Staff-Surgeon, might take two servants by mail steamer at Government expense, when I could not pay for my wife and children; and yet if I don't take the servants, they won't give me the money. I wonder this view of things has not been 'shown up;' I had thought of writing about it, but expected that perhaps some one else would, or that some fellow who had

left the service would. The youngsters look at the present, and are dazzled by the gilding on the gingerbread, but forget *respicere ad finem*; or if they look, are caught by the retiring allowance, forgetting how few live to reach it, and of that few how many enjoy it any time. Take the pay of a Surgeon, deduct stoppages for band and mess, expense of moving, with loss upon furniture, &c. (if on the Staff there is no band or mess, but the moves are much more frequent), and see what professional income it represents. Deduct from that discomfort of an Arab make-shift existence, bad climates, not only for yourself (for a medical man's life must always be hard), but for your wife and children, who at least in civil life enjoy comfort and the society of family and friends."

THE EXAMINATION OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—In your last number there appeared a letter in which, either wilfully or accidentally, a number of erroneous statements were put forward as facts; and I would be much obliged if you would permit me to put forward the truth on these points. I refer to the letter of "A Student" respecting the Edinburgh double qualification, in which it is stated—1st, that there are no grinders in Edinburgh; 2nd, that no students grind for the license in that city; 3rd, that no man ever goes in for the examination of the Irish College without grinding; 4th, that the examination in Edinburgh is not reputed to be easier than that of the Dublin College of Surgeons. Now, with regard to the first of these. To my certain knowledge, there are at least four grinders in Edinburgh. Secondly, I have known very many men—in fact the majority of the Irish students—who have gone over to the Edinburgh College, who have been prepared by grinders for that qualification. Thirdly, although most of the Dublin students do not try to combat the examination without the aid of grinding, yet I have known a good many men who have passed by the means of the knowledge derived from the ordinary means of instruction. Fourthly, it is a very well known fact that the instances are not few of men who have obtained the Edinburgh qualification after being rejected at the London and Dublin Colleges. Surely it is a sign of a weak cause for anyone to try and pass unfounded assertions as facts; and it is but common justice to let it be known that the main reason why a cheaper and inferior qualification is sought for, is, in the majority of cases, that the candidates are too conscious of their own ignorance to face an examination second to none in Britain. True it is a minute examination; but I appeal to any student who has ever sat before the Court of Examiners, or to any auditor who has listened to the questions, if ever any subjects have been examined on which are not to be found in books, or which should not be known by one who thoroughly knew his business.—I remain, dear Sir, faithfully yours,

L.R.C.S.I.

Parliamentary Intelligence.

HOUSE OF LORDS.—APRIL 20.

STRAND UNION WORKHOUSE.

THE MARQUIS OF TOWNSHEND asked her Majesty's Government what explanation could be given for the continuance of the practice of carpet beating in the Strand union workhouse, notwithstanding the urgent remonstrances made against it many months since; whether any, and if so, what improvements had been made in the general arrangements of the casual wards of that workhouse, respecting which complaints were made also some months since, and what number of cubic feet of air was apportioned to each inmate in the ordinary wards of the workhouse.

EARL GRANVILLE was understood to say in reply, that as to the carpet beating the matter had been referred to the workhouse committee, and the answer they gave was that no complaint had ever been received from the medical

officer or the inmates of the workhouse with regard to it. As to the general arrangements of the casual ward, the Poor-law Board had not received any complaints on the subject; but improvements had taken place in them and a new ward had been added. With regard to the last question, he thought the noble Marquis had been misinformed as to the accommodation which the Poor-law Board required for each inmate—it was 300 feet, not 1000 feet.

THE CATTLE PLAGUE.

THE DUKE OF BUCKINGHAM and CHANDOS asked the Lord President what arrangements had been made by the Privy Council for the experimental treatment of animals suffering from cattle plague, under the provisions of the Cattle Diseases Act, and how many animals had been or were now under treatment, and whether the assent of the local authorities of the district had been obtained in such cases. He remarked that as the period for which the Cattle Diseases Bill was passed had nearly expired it was desirable that the public should be made acquainted with the result of the operations of that act. Under the act of parliament of this session powers were given for the slaughter of animals affected by disease; and the result of the working of the act had been that in many places the disease had been stamped out though at the cost of a considerable loss of that description of property. The act also gave powers for the retention of cattle for experimental treatment. The magistrates at Buckingham were not aware that any animals were so retained till a complaint was brought before them a few days ago that certain animals were, as the complainants believed, improperly retained. It was stated, that an order in council had been issued, giving the power to retain animals for experimental treatment. In this case twelve animals were being treated in a yard, and were permitted to be so treated. Unfortunately, however, the yard was badly drained, and it was in close proximity to the public roads of the county.

HOUSE OF COMMONS.—APRIL 12TH.

CATTLE DISEASES PREVENTION ACT.

In answer to a question,

SIR G. GREY said that no specific information had been received that the local authorities in any county or in any part of Great Britain had failed to carry out the provisions of the Act. He received one complaint in reference to a district in Staffordshire, and he addressed inquiries to the lord lieutenant of that county, and he had since received through him a very full answer from the magistrate whose conduct was complained of, which was perfectly satisfactory. It was to the effect that he had not refused to carry out those provisions of the Act. He had that day received a memorial from the Chamber of Agriculture in Edinburgh and the Scotch Farmers' Club, that some local authorities had refused to execute some of the powers conferred upon them, but no specific instances were given; and it was impossible to act upon mere general statements.

CATTLE PLAGUE COMMISSION.

In reply to a question,

MR. BRUCE said he expected that the third report of the Cattle Plague Commission would be published about the end of the present month. The commission was engaged in making certain elaborate medical investigations which required much time.

APRIL 13TH.

THE CATTLE PLAGUE

MR. DU CANE inquired if the attention of the Secretary for the Home Department had been turned to a report which appeared in the *Times* of that day of certain statements made at the Middlesex Sessions on the previous day, to the effect that Dutch cattle in a state of disease had been introduced at Blackwall, having been smuggled in by the agents of Lord Granville and Col. Talbot.

SIR G. GREY said he knew nothing of the report except from the fact of its having been shown to him a few minutes since. He would make inquiries respecting it.

APRIL 16TH.

SURGEONS IN THE GUARDS.

COLONEL C. LINDSAY asked the Secretary of State for War whether he would state the reason of the proposed change of system in the promotion to the rank of surgeon in the brigade of Guards; whether the existing system of regimental promotion had ever been known to fail, and whether

public advantage was likely to be derived from the proposed change.

The Marquis of HARTINGTON said that, in order to afford a complete reply to that question, it would be necessary for him to enter in a variety of details which he thought it would be better to defer until the motion of his hon. friend the Member for Fifeshire (Sir R. Anstruther) in reference to that subject should come on for discussion.

THE CATTLE PLAGUE

In reply to the question by Mr. DU CANE,

Sir G. GREY said that he did not think it would be advisable to bring in a Bill for consolidating and extending the Factories Acts, until a commission which was inquiring into the expediency of embracing certain other trades within the operations of those Acts should have made its report. The right hon. baronet then proceeded to state that he would take that opportunity of giving all the information in his power with respect to a subject on which a question had been addressed to him a few evenings previously by the hon. member for Essex. That question related to the introduction of diseased Dutch cattle, or cattle supposed to be diseased, into the farms of Lord Granville and Colonel Talbot in the immediate neighbourhood of the metropolitan district. The subject had that day been brought under the notice of the local magistrates; and it having appeared from the evidence that the cattle had been driven to Lord Granville's farm from an adjoining farm to which they had been conveyed after it had been certified that they were free from disease, the magistrates unanimously dismissed the case against the noble lord. Colonel Talbot had already explained in the public press that the cattle had been driven by the dealer to his farm after a licence had been obtained from Sir R. Mayne; but it did not appear that in either of these cases the animals had been instrumental in spreading the disease.

APRIL 17TH.

VACCINATION BILL.

On the motion of Mr. BRUCE, the following members were nominated as the select committee on the Vaccination Bill:—Mr. Bruce, Mr. Henley, Mr. Lowe, Sir J. Pakington, Mr. P. Scrope, Mr. Mitford, Mr. Enfield, Mr. Barnett, Mr. Evans, Mr. E. Egerton, Lord Henley, Mr. Selater-Booth, Mr. Hibbert, Mr. A. Egerton, Mr. Candlish, Mr. Reed, and Mr. O. Standley.

THE SMOKE NUISANCE.

Sir R. PEEL asked the Home Secretary when it was intended to introduce the promised bill on the subject of the nuisance resulting from the smoke of furnaces in towns and country districts.

Sir G. GREY replied that when his right hon. friend brought the subject before the House, he thought he was under a mistake that the smoke nuisance arose from the absence of any restrictive law. He thought it rather arose from a laxity of the authorities in instituting prosecutions. He had addressed a circular to some of the largest towns in the kingdom, making inquiries as to the facts of the case, and the answers had shown that in every one of those towns, there was a law in force requiring the consumption of smoke or the abatement of nuisance arising therefrom, and also that there was a great variety as to the manner in which the law was enforced. He would lay the circular before the House, together with a tabular statement of the results and the various answers received. A bill was now in preparation by the Vice-President of the Council, one object of which was to provide summary means, not only with respect to the abating the smoke nuisance, but also other nuisances with regard to which the local authorities would be compelled to do their duty.

THE PUBLIC HEALTH ACTS.

Lord M. MONTAGU asked the Vice-President of the committee of Council whether the Government had any intention to introduce a bill to amend the Public Health Acts; and whether it would contain any clauses which dealt with the pollution of rivers, in accordance with the recent report of the commissioners.

Mr. BRUCE said he thought he should shortly be able to lay on the table a bill for the amendment of the Public Health Acts. That measure, however, would not contain any clauses relating to the pollution of rivers.

Earl GRANVILLE was understood to reply that he had already stated in the House that the Government had referred the whole of this question to a Royal Commission, who had

been labouring on the subject for a very considerable time. They thought it better not to communicate to the Government the results of their labours as they went on, but to confine it to one general report, which he believed would be ready at the end of this month. On that report it might be necessary for the Government to take further proceedings. They had thought it much better that two departments should not be conducting the same business at the same time, and, therefore, authority had been given to the commissioners. Applications had been made to allow two individuals to make experiments, but he was not aware that they had been very successful.

THE LONDON SICK POOR.

On Saturday (April 14th) a large body of noblemen and gentlemen attended at the Poor-law Board, Whitehall, as a deputation from the meeting which was held a few weeks since at Willis's Rooms, with respect to the condition of the sick poor in workhouse infirmaries.

The deputation was received by the Right Hon. C. P. Villiers.

Lord CARNARVON observed that there was not a single sentence in all the resolutions passed at the meeting held at Willis's Rooms which was not distinctly borne out by facts. The medical attendance was insufficient, the buildings were proved to be unhealthy, and the staff of nurses was nothing like proportionate to the wants of those who were in these places. There was no hope of improvement being effected in the workhouse infirmaries by those who had the administration in their hands; and they now came before the right hon. gentleman to appeal to him, as President of the Poor-law Board, and as representing her Majesty's Government, to deal with a state of things disgraceful at once to society and to the administration of the law.

The Archbishop of York spoke of the manner in which Boards of Guardians defied the authority of the Board; and said, amid loud cheers, that the public would never rest contented until the Poor-law Board had more powers over these guardians.

Dr. ROGERS, the medical officer of the Strand Union, expressed the hope that the inquiry being made by the Board would be full and free, and said that he knew, as medical officer for ten years of an union, that the reports published were as to workhouse mismanagement greatly within the truth, for the public, instead of being simply disgusted, would be horrified if the whole truth could be known.

The Earl of SHAFTESBURY urged that the inquiry being made by the order of the Poor-law Board ought to be conducted by independent medical gentlemen.

Mr. ERNEST HART stated that the *minimum* of space which ought to be allowed in hospitals was nearly two-thirds more than is given in almost every London workhouse infirmary.

The PRESIDENT could give no definite reply to the propositions. He felt, and he was sure the public must feel, deeply indebted to this association for the inquiries which had been instituted, and for the effective manner in which the results of those inquiries had been made known in the effort to reform the system of which they complained. He felt bound to say that he had seldom known a more humane and Christian-like labour undertaken than that of improving the condition of the sick in the workhouse infirmaries of this great city. Many of the things which the association had observed had not taken him by surprise, for cases had often, too often, arisen in these houses, and come before the Board, showing that the hospital arrangements of the houses were still very defective, and, indeed, he was not indisposed in consequence to agree substantially with the terms of the resolution passed at the meeting—namely, "That the present management of the sick in the metropolitan workhouses is unsatisfactory; that the buildings are, in some cases, inadequate, the medical attendance insufficient, and the nursing merely nominal." Referring to the statements with respect to the inquiry instituted by the Board, he said, the fact that the inquiry was being carried out by Dr. Smith and Mr. Farnall, guaranteed that it would be full and impartial. An inquiry had certainly been made, but it was, in one sense, private in its character. He alluded to that instituted by the proprietors of the *Lancet*. He begged to say that he had never questioned the capacity or the good faith of the gentlemen who had made that inquiry, and he had yet to learn that there had been any overstatements in the cases they had apparently established. He feared, how-

ever, that the difficulty in this case was not so much in getting at the truth, as in giving effect to the remedy suggested. He was certainly not prepared to dispute the conclusions at which the deputation had arrived; and the remedy proposed was, he understood, that there should be six separate hospitals for the sick at present lodged in the metropolitan workhouse infirmaries. The meeting must not lose sight of the fact that such a scheme involved a great change in the principle upon which the poor were now maintained in this country. That charge was now local, whereas this scheme would treat the sick poor as belonging to the whole metropolis. He did not say it would be wrong on that account; but the system was one of which the community was extremely tenacious. There had always been a difficulty as to the hands in which the administration of the Poor-law should be placed, and the great dread of the legislature had been that there would be lax and wasteful expenditure, if the administration was not in the hands of those directly interested in the economy of the funds. Some guardians performed their duties with judgment and humanity, but, as the chief duty which they had to perform was what was termed "to keep down the expenditure," it was somewhat of a chance when guardians were found possessing all the qualities required for a wise administration of the law. The right hon. gentleman said he thought that if the House of Commons would alter the present system of rating in the metropolis, it would do so for the sick poor, and have a general rate, as in the case of the casual poor. He concluded, amid loud cheers, that though he could not pledge the Government in the matter, he could assure the deputation that nothing should be wanting on his part in recommending the propositions for favourable consideration.

LEGAL INTELLIGENCE.

BAIL COURT.—APRIL 17.

(Sittings at Nisi Prius at Westminster, before Mr. Justice MELLOR and a Common Jury.)

YOUNG v. HAMILTON.

THIS was an action to recover compensation in damages for the wrongful treatment of the plaintiff by the defendant.

Mr. Ribton and Mr. Besley appeared for the plaintiff; the defendant did not appear.

The plaintiff is a farm labourer, residing at Newdegate, in Surrey, and the defendant is the proprietor of an "anatomical museum" at 404, Oxford-street. About nine months previous to June last, the plaintiff had been in the hospital. Passing along Oxford-street, he went into the defendant's museum, and as he had some spots about his face, he was asked what was the matter with him. He replied that he was not altogether right, upon which he was taken into the consulting room. The defendant told him he was ill, and that he had better be cured, and that he was suffering from the effects of disease. A discussion took place between them about the price, when the plaintiff said the defendant agreed to make a perfect cure for five guineas. Plaintiff gave defendant half a guinea, had a bottle of physic, and gave sixpence for a small book. He returned on June 26th and paid 4½ guineas, the remainder of the money. He continued to take the medicine, but got no better. Defendant then said that, to make a complete cure, he must have six guineas more. Plaintiff called him a blackguard, and after some conversation the defendant said he would act like a man to make a perfect cure of him. The money was ultimately paid, and the plaintiff went on taking the medicine supplied by the defendant, but got no better; in fact, he was very unwell. Defendant then said he must have nine guineas more before he could make the cure, observing that he was charging moderately, as he often got forty guineas for effecting a cure. Plaintiff again called the defendant a blackguard, and said he had no more money, and left. Plaintiff afterwards called on the defendant and told him how ill he was, but that he had no more money. Defendant asked him in and to sit down, and at his request he had another bottle of medicine. When he said how ill he was defendant said it served him right, and that if he had liked he could have given him medicine that would have killed him in a minute. Plaintiff, however, had another bottle.

Mr. Justice Mellor: What! after what he had said about killing you in a minute?

Plaintiff: Yes. I wanted to see what he would do (laughter). He gave the defendant half a guinea for the medicine. He took a little of it, threw some of it away, and gave the remainder to Mr. Donoghue, a medical man in the Westminster-road. The medicine made the plaintiff weaker every day. It made his mouth and gums sore and his teeth loose, and he swelled out as big again as he should have been. He earned 3s. per day wages, and when under the defendant's treatment he was unable to work for a month.

Mr. Donoghue proved that he found the plaintiff suffering from excessive salivation, and his general health much debilitated. He analyzed the contents of the bottle and found it to contain a strong preparation of bichloride of mercury. Plaintiff's was a very trifling case, and in his opinion he had not been properly treated. There was no need of the use of mercury. He attended the plaintiff about two months and cured him. His charge amounted to between £8 and £10.

The learned Judge, in summing up, said if the jury believed that defendant undertook the cure of the plaintiff he was bound to perform his contract. No man of learning in the profession would make such a bargain, but only the practitioner in such an abominable system of quackery as that followed by the defendant. The plaintiff was first shown the symptoms of a certain complaint, and then when he was a fit subject for credulity to work upon he was told that for five guineas he could be perfectly cured, and having paid that sum he was induced to go on paying other moneys. The plaintiff was entitled to recover back the money he had paid, for his loss of time, and the doctor's bill, besides something for his suffering.

The jury returned a verdict for the plaintiff, damages £60.

ALLEGED LITERARY PIRACY.

MARLBOROUGH-STREET.

DR. JOHN HARVEY of No. 31, Grosvenor-street, waited on Mr. Tyrwhitt to solicit his advice in the following matter. He was the author of a work on the "Nervous Functions," and a copy of the *Worcester Herald* being forwarded to him he found amongst the advertisements one of a work bearing the same title as his own, purporting to be written by a "London Physician." He procured a copy of this work, and found that it was written by Dr. Hammond, whose name was not in the "Medical Directory," but was in a book called "Quacks and Quackery," reprinted from the *Medical Circular*.

Mr. Tyrwhitt remarked there appeared to be a piracy.

Dr. Harvey said on looking at the work he found it bore a different title to that of his work, the title of his work being only used in the advertisement.

Mr. Tyrwhitt said the applicant might go to the Court of Chancery for an injunction.

Dr. Harvey said it would be perfectly useless to commence law proceedings against this person.

Mr. Tyrwhitt asked if any portion of his (Dr. Harvey's) work had been pirated.

Dr. Harvey was not aware that such had been the case. The advertisement in the country paper was calculated to do him much injury, besides causing him great annoyance.

Mr. Tyrwhitt, having looked at the book, and the advertisement, said the matter clearly had the appearance of an attempt to deceive. The press would, however, afford the best redress, it being very hard that the applicant should either have to appeal at a great expense to the Court of Chancery, or sit down and put up with the injury to his reputation.

Dr. Harvey thanked the magistrate and left the court.

BEQUESTS.—Miss M. F. Woodburn of Kensington Park Gardens, lately deceased, has bequeathed large sums to several charitable institutions, and has not forgotten some of our most deserving medical institutions;—as the Hospital for Consumption, Brompton, £1000; St. Mary's Hospital, Paddington, £500; the Metropolitan Convalescent Institution, £300, the Sea-side Convalescent Hospital, £300; the City of London Hospital for Diseases of the Chest, £300; the Nottingham and Shepherd's-Bush Dispensary, £300; the Royal National Sea-bathing Infirmary, £200; the Westbourne Dispensary, £200; and the Kensington Dispensary, £50. All legacies to be paid free of duty.

THE ENGLISH VACCINATION BILL.

At a meeting of the Yorkshire Registrars of Births and Deaths, held at Leeds on March 10th, to take into consideration the new Vaccination Bill introduced by Mr. Bruce into Parliament, Mr. J. K. Heaps in the chair, the various clauses of the new Vaccination Bill having been read, it was resolved, "That this meeting considers that the Remuneration Clause, No. 23, is very unsatisfactory." The Clause is as follows:—"Every registrar shall keep a book in which he shall enter the notices of vaccination given by him, and also the certificates transmitted to him, and shall upon demand give a copy of any entry in the same, on payment of one shilling for each search and sixpence for each copy; and every registrar shall receive one penny for every child whose birth he shall have registered, and for whom he shall give the notice, and *threepence* for every child whose vaccination he shall have registered, and he shall receive *one penny* for each child whose vaccination he shall have registered without having registered the birth." It was resolved, "That in the opinion of this meeting the remuneration should be *threepence* for giving the notice and entering the particulars required in the Vaccination Book, and the further sum of not less than *two-pence* for completing the entry on receipt of the vaccinator's certificate."

RETROSPECT OF THE JOURNALS.

APRIL 21.

THE *Lancet* devotes a leader to Professor Huxley, who has just finished his Hunterian Lectures at the College of Surgeons. There are few who will not admit that he is probably the foremost among English comparative anatomists. Even if his vast knowledge of his subject were put out of the question, he would rank first as a popular lecturer. His style is so simple, devoid of technicality and pedantry, that a person hitherto ignorant of the topic could not fail but to come away enlightened. Though original he is honest, and cheerfully alludes to the labours of others. Many an author long since forgotten has been brought to public notice by the present Hunterian Professor of the College of Surgeons.

The provisions of the Canadian Medical Act are reviewed. As might be expected, it is formed much on the type of our own, but modified by the experience gained from the manifest inadequateness of the latter to deal with certain cases; one of the principal points of difference lies in the method of electing the representatives, they are proposed to be elected much in the same way as members of Parliament are, by the medical men of the different districts, and not by the educational bodies; it would be well if we took a lesson from our colonial brethren in this particular.

Mr. Paul Swain, late house-surgeon, has gained the Jacksonian prize for his essay on excision of the knee *versus* amputation. The result might be anticipated when we take into account the school from which Mr. Swain hails, where the splendid success of Sir William Fergusson in this his favourite operation has laid the foundation for a new line of practice in conservative surgery.

Dr. Farrs estimates that there are a million of childless families in England and Wales; he does not approve of the Foundling Hospital system, but suggests that much good might be done by the adoption by the childless rich of some of the superfluous offspring of their poorer neighbours.

The *Lancet* highly commends the action of the Cork Medical Protective Association, the main success of which is to be attributed to the indefatigable and popular secretary, Dr. Armstrong. It says:—

"The Cork Association also brings its influence to bear on the members of Parliament of the county and city. If similar associations, acting with equal energy, were established throughout the kingdom, the medical profession might speak in a language which Parliament could not fail to understand of the gross injustice to which the pro-

fession are in many respects subjected: of their just claims to a more liberal treatment at the hands of the Commander-in-Chief and the Lords of the Admiralty; of their ill-requited services as union surgeons; and of their want of protection from the assumptions and rascalities of quacks and impostors."

Mr. T. Holmes, the Chief Surgeon to the Police, has been allowed by the Home Secretary to engage in private practice, in consideration for which he has relinquished a portion of the emoluments.

Dr. F. Winslow's reply to Dr. Tuke is published.

Dr. J. Pollock suggests phosphorus as a disinfectant.

At the anniversary festival of University College Hospital, the chair was taken by the Duke of Cambridge, who in his speech alluded to the position of the medical officers of the army, and called on the eminent medical men around him to endeavour to remove the feeling of distrust with which they regarded the action of the authorities.

Dr. Buchanan of Glasgow has excised the tongue in the manner recommended by Professor Syme. The patient died on the ninth day of pyæmia.

By the *British Medical Journal* we learn that the guardians of St. Pancras are still determined to keep themselves in hot water. Miss Coutts has ventured to remonstrate with them, but instead of acknowledging their errors, they virtuperate the Archbishop of Canterbury, Lord Carnarvon, the medical men, and in fact any one who dares to point out their shortcomings.

The treatment of the insane in America is very bad. After enumerating some disgusting details, "it is unnecessary," adds the *Philadelphia Medical and Surgical Reporter*, "to further enumerate this catalogue of shamefully inhuman treatment of the insane. One thousand three hundred and forty-five insane are confined in the poor-houses of New York in this manner, of whom 386 are capable of more or less labour."

SANITARY MEASURES AND THEIR RESULTS IN CROYDON.

DR. WESTALL, in a very able work on the advantages to be derived from the adoption of the Local Government Act, as exemplified in Croydon, gives a report of the good results following upon sanitary measures, which is most encouraging. The result of the modern improvements in Croydon, is a large decrease of sickness, especially amongst the poorer classes; a very large increase in population, the birth-rate increasing from 2.91 to 3.14 per cent., and the deaths decreasing from 2.366 to 1.845 in the thousand, showing a saving of above 200 lives per annum. Excepting in extreme infancy, the average deaths at all ages have materially decreased; and, even when the infant deaths are taken at the old rate, all those under twenty years of age have decreased by nearly 10 per cent. Taking the deaths from fever and all zymotic diseases alone, the decrease is respectively from 6.1 per cent. to 3.1 per cent., and from 22.5 per cent. to 17.2 per cent., taking from the year 1845, and including the two unhealthy seasons of the years 1863-64.

These, then, are some of the results of the application of the Local Government Act (patent to all) to Croydon, a town in many respects not most advantageously situated, by reason of its proximity to London, of which, in fact, it is a suburb; and by its being the chief town of a large agricultural district, the majority of the lower classes, male and female, obtaining their livelihood by out-of-door work, and thus, perhaps, greatly accounting for the large infant mortality; also by the daily passing through of a large number of tramps; and again, as containing the union-house for nine parishes and two hamlets, for which no deduction has been made in the calculations. That there are results far higher than these, of a religious and moral character, we may be assured; and the Croydon ratepayers may well be satisfied that they have not exercised a large amount of self-denial and perseverance in vain, but that they have added somewhat to the improvement of their fellow-men, and thus, humbly though it be, joined in the tribute of glory and praise to Him who gave us so great an example of beneficence, and have endeavoured to fulfil their highest duty on earth.

LIST OF ENTRIES IN THE BRANCH MEDICAL COUNCIL (IRELAND), FOR FEBRUARY AND MARCH, 1866.

- David Moore, 3, Donegal-square, South, Belfast, L. 1866, and L. in Midwifery, 1866, K.Q.C.P.I.
- William John Grier, Granard, county Longford, L.R.C.P. Edin., 1866; L.R.C.S.Phys., 1866.
- Bourke Long, Great George's-street, Cork, L.R.C.P.Edin., 1865; L.R.C.S.Edin., 1865.
- Patrick Brady, Lissacoppel, Billeis, Virginia, county Cavan, L.R.C.S.I., 1865; L.R.C.P.I., 1866.
- John Wm. Yorke Fishbourne, Ferns, county Wexford, M.D. Univ. Dub., 1864; Mast. Surg. Univ. Dub., 1865.
- Josias Wilson Patrick, Carrickfergus, county Antrim, L.R.C.S.Edin., 1865; L.R.C.P.Edin., 1865.
- Wellington Gray, 5, Trinity College, Dublin, Lic. Med. Un. Dub., 1865; L. Surg. Un. Dub., 1866.
- Charles Edwin McVittie, Dr. Steevens' Hospital, Dublin, L.R.C.S.Irel., 1865; L.R.C.P.Edin., 1866.
- Frank Thorpe Porter, 15, Upper Merrion-street, Dublin, L. 1865, and L. in Midwif. 1865, K.Q.C.P.I.; L.R.C.S.I., 1864.
- Richard Murray Vesey, St. Peter's, Drogheda, county Louth, L. in Med. Univ. Dub., 1865; L. Surg. Univ. Dub. 1866.
- Wm. Alexander Thompson, 132, Leinster-road, Rathmines, county Dublin, L.R.C.S.I., 1865; L. 1865, and L. Midwif. 1865, K.Q.C.P.I.
- Mathew Arkins, 144, Herbert-terrace, Dublin, L.R.C.S.I. 1865.
- Thomas Wm. Patterson, 6, Haddington-terrace, Kingstown, L.R.C.S.I., 1865; L. 1865, and L. Midw., 1865, K.Q.C.P.I.
- Patrick Heas, 28, Grenville-quay, Cork, M.D.Q.U.I., 1865. Mast. Surg. Q.U.I., 1865.
- Wm. Flack. Stevenson, county Dublin, M.B. 1865, and Mast. Surg. 1865, Univ. Dub.
- Daniel O'Connell Raye, county Dublin, M.D.Q.U.I. 1865. L.R.C.S.I. 1865.
- Thomas O'Hare, Newry, L.R.C.S.Ed. 1865.

- Wm. Blacker Anster, Dub. L.R.C.S.I. 1866.

It is proposed to establish in Chelsea an hospital for the reception of children under fifteen years of age.

Meetings of Scientific Societies.

ASIATIC.—April 9.—Mr. Thomas, advertising to recent controversies respecting the parentage of the various modes of writing in use in ancient India, spoke "On the Adapted Alphabets of the Aryan Races." The Aryans invented no alphabet of their own for their special form of human speech, but were, in all their migrations, indebted to the nationality amid whom they settled for their instruction in the science of writing.

LINNEAN.—April 5.—The following papers were read: "On a New British Fungus," by the Rev. M. J. Berkeley, M.A.—"On some Undescribed Species of Teredo, from Australia," by Dr. E. P. Wright.—"Note on the Presence of Stamens within the Ovarium of *Backea diosmefolia*, Rudge," by Dr. M. T. Masters.

ENTOMOLOGICAL.—April 2.—Mr. W. W. Saunders exhibited a number of eggs, probably of a *Chrysopa*, arranged in a line or chain on the bark of a tree, each egg being supported by a pedicel which raised it about a quarter of an inch above the level of the bark. The eggs were ovate-elongate; the first, third, fifth, and so on, were deposited longitudinally, and supported by pedicels at right angles to the bark; whilst the second, fourth, sixth, and so on, were placed transversely, and supported by pedicels inclined to the plane of the bark at an angle of 45° or thereabouts. Also, a larva, probably of a Lamellicorn beetle, which had two fungoid excrescences (*Sphæria*) projecting from the neck, one on each side, like rams' horns. Also, four larvæ of a species of Locustide, attached to a small branch, and so tightly entangled in one another's legs that they seemed to have been unable to extricate themselves, and had consequently died. The whole of these interesting objects were from New South Wales.—Mr. W. Rogers sent for exhibition specimens of the Ichneumon, *Pimpla oculatoria*, which he had bred from the egg-bag of a spider, found under the loose bark of an oak fence.—Mr. F. Smyth and Mr. Desvignes mentioned that they had frequently bred that insect, but always from bramble-sticks.—Mr. J. Jenner Weir exhibited some larvæ, which he believed to be only the common meal-worm, *Tenebrio*, but which had been found in the corks of port wine. Considerable damage had been done, since they ate quite through the cork, and allowed the wine to escape. He suggested the use of bran instead of sawdust as the probable cause of their incursion into the cellar.—Mr. W. W. Saunders remembered an instance of a number of larvæ of *Dermestes lardarius*, which were brought into the docks with a cargo of skins, effecting an entry into an adjoining warehouse, where they perforated and rendered entirely useless a quantity of manufactured corks.—Mr. F. Smith exhibited a specimen of *Bembex olivacea*, placed in his hands by a gentleman at Bristol, to whom it was given, many years ago, by a Dr. Hicks, who said that he had captured it himself near Gloucester; the insect was figured by Donovan (under the name *B. 8-punctata*), but no precise locality was given, and it had long been doubted as a British species.

ROYAL INSTITUTION.—March 16.—"On the existence of a Material Medium pervading Space," by Mr. B. Stewart.—March 23.—"On the Existence in the Textures of Animals of a Fluorescent Substance closely resembling Quinine," by Mr. H. B. Jones.

SOCIETY OF ARTS.—April 4.—The paper read was, "On the Manufacture of Sugar, and the Machinery employed for Colonial and Home Purposes," by Mr. N. P. Burgh.

CONSOLATION.—A letter from Berlin says:—"Considering the enormous rise in the price of meat which the rinderpest will probably occasion within a very few months it may be interesting to your readers to hear of the great success which has attended the introduction of horseflesh in Berlin as an article of human food. In 1860 the number of horses slaughtered for this purpose was 613, in 1861 it was 700, but in 1864 it had increased to 1742, and in 1865 to 2241. The meat is perfectly wholesome and very tolerably palatable, resembling rather coarse beef. Grand dinners have been given by the society interested in its introduction, at which horseflesh alone was produced, though prepared in various ways. Old cab-horses, wall-eyed and broken-kneed, are found to be delicious eating when treated by a really artistic hand."—*Express*.

Notices to Correspondents.

Dr. James Crawford (Longridge, Whiteburn).—As the case is presented to us, it appears that Dr. C. has been guilty of a breach of professional etiquette. It is to be regretted that no other means exist of rectifying such misunderstandings between professional men, than by referring the questions at issue to the arbitration of professional friends, and we hope that Dr. Crawford, who seems to have just grounds of complaint, will adopt this course.

A Scotch M.D. and Surgeon can recover for medical and surgical attendance—namely, visits.

Provincial.—The flint instruments supposed to prove the great antiquity of the human race are now to be seen in many museums. There are several in the British Museum in the fossil department.

A Surgeon shall receive a private note.

Dr. W. is thanked for his communication, and we shall be glad to hear from him again.

Mr. C. P.—The letter has been received.

Philos.—The permanganate of potash owes its disinfecting power to the large amount of oxygen it contains, permanganic acid consisting of one part of manganese and seven of oxygen.

The Royal Institution.—The notice and report have been received.

A Subscriber.—The precipitate in all probability was cream of tartar; the acid and the spirit of the additional wine taking up the oxide of iron.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At a general meeting of the Fellows held on Monday, the 16th inst., the following gentlemen, having undergone the necessary examination, and satisfied the College of their proficiency in the Science and Practice of Medicine, Surgery, and Midwifery, were duly admitted to practise Physic as Licentiates of the College:—

Brooke, Thomas Thornhill, Stockport.
 Dunn, George Carr, Stanley-gardens.
 Ellery, Henry James, St. Stephen's by Saltash, Cornwall.
 Garman, John Cooper, Wednesbury, Staffordshire.
 Griffiths, Richard Samuel Purnell, Undley-place, Harrow-road.
 Hicks, George, Augustus, Turquay.
 Hoffmeister, William, M.D. Heidelberg, Cowes, Isle of Wight.
 Lynch, Jordan Roche, Horbury-terrace, Notting-hill.
 Slaughter, George Monias, Fort Pitt, Chatham.
 Wise, Thomas, Castletown, Isle of Man.

At the same meeting the following were reported by the examiners to have passed their Primary Examinations:—

Robert Vacy Ash, St. Mary's Hospital; George William Barroll, St. George's Hospital; George Erp Burton, Liverpool; Edward Noble Edwards, Guy's Hospital; William Betts Giles, Guy's Hospital; Thomas George Palmer Hallett, University College; Richard Clement Lucas, Guy's Hospital; Wm. Gordon Maddox, University College; John Aaron James Timmins, St. Bartholomew's Hospital; John Graves Wiseman, Guy's Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 17th inst., and when eligible will be admitted to the pass examination:—

Edward Colson, J. A. Sharp, J. F. P. McConnell, Benjamin Walker, Lancelot Newton, Joseph Cabe, T. J. Burroughs, W. T. Thurston, Charles Wade, E. R. Evans, J. R. Morgan, W. W. Saul, J. M. Kirkman, R. L. Sheffield, R. Heathcote, Leonard Smith, G. E. Norton, Henry Bland, J. R. Fielding, J. B. Ryley, Joshua Duke, Henry Gould, H. T. Butler, William Little, H. E. Juler, A. C. Air, and Samuel Ridwell.

The following passed their examination on the 18th inst.:—

W. H. Wood, Joseph Massingham, J. R. Lazenby, J. W. Blandford, T. H. Pinder, Robert Laing, J. T. Fox, Edward Young, C. W. Chapman, A. O. McKellar, Alfred Peon, Clifford Crew, George Amsten, C. W. Milne, Frederick Pollard, Samuel Alford, E. W. Minter, Arthur Atkinson, Charles Aldridge, Reginald Bayley, Charles Richardson, F. B. Besly, Henry Casc, G. A. Woods, T. H. Hickman, Peter Ryder, J. F. Goodhart, J. E. Burton, Walter Hart, J. F. Codrington, Alfred Trubshaw, and P. T. Scott.

ELECTION OF MEDICAL OFFICERS TO THE NEW SURREY COUNTY HOSPITAL AT GUILDFORD.—This institution is now completed, and will be very soon opened for the reception of patients. The election of Medical Officers took place on Tuesday, the 17th, when the three gentlemen at the top of the poll were elected. The number of votes stood thus:—Mr. Henry Taylor, 174; Dr. J. R. Stedman, 162; Mr. R. Eager, 122; Mr. F. Yate, 97; Mr. T. J. Sells, 58.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—During the past fortnight 216 gentlemen have gone through their

primary examinations at the above institution in Anatomy and Physiology. Last week 9 were referred first day, 4 second, and 6 on the third day—total 19, out of the 108 candidates, failed to acquit themselves to the satisfaction of the court, and consequently were referred back to their studies for three months.

THE JACKSONIAN PRIZE.—The Council of the Royal College of Surgeons has just awarded one of the Jacksonian Prizes to Mr. William Paul Swain of Devonport, a member of the College, for his essay on "The Diseased Conditions of the Knee-joint which require Amputation of the Limb, and of those Conditions which are favourable for Excision of the Joint; with an Explanation of the relative Advantages of both Operations, as far as can be ascertained by Cases properly authenticated." It does not appear that any competition took place for the other prize subject, on "The Relative Value of the various Modes of Treatment of Poplital Aneurism."

The statue of Laennec has already been commenced, and will figure in the Exhibition of 1867. M. Lequesne is the artist. It will eventually be fixed in Quimper, Laennec's own country district.

ROYAL SOCIETY.—On Monday evening the Society held its tenth meeting for the season, Professor Christison in the chair. Papers were read by Dr. John Davy on "Incubation," by Dr. Stevenson Macadam on the "Absorption of Substances from Solution by Carboniferous Matters," and by Drs. John Smith and Traquair on "A New Genus of Ganoid Fish from Calabar."

FEVER IN GLASGOW.—Dr. Gairdner reports that during the last fortnight 126 cases of fever had occurred, as compared with 151 during the two preceding weeks; and this is the lowest return that has been made during the past twelve months.

DEATH OF DR. MARR.—This esteemed gentleman died at his residence in Brandon-street, Edinburgh, on the 14th instant. Although latterly he had entirely relinquished practice, he was at one time a lecturer on midwifery in the Extra Academical School. He was highly esteemed by his medical brethren, and a general favourite in society.

BIRTHS and DEATHS Registered and METEOROLOGY during the Week ending Saturday, April 14, 1866, in the following large Towns:

Boroughs, etc.	Estimated Population in middle of the Year 1866.	Persons to an Acre. (1866.)	Births registered during the week ending April 14.		Deaths.	Temperature of Air (Fahr.)		Rain Fall. In Inches.	In Tons per Acre.	
			Corrected Average Weekly Number.	Registered during the week ending April 14.		Highest during the Week.	Lowest during the Week.

Vienna	(1863) 590,000

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29.710 in. The barometrical reading increased from 29.17 in. on Wednesday to 29.96 in. at the end of the week.

The general direction of the wind was S.W.
 * The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the 10 years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The mean temperature at Greenwich during same week was 42.4 deg.

MEDICAL APPOINTMENTS.

LONDON.

SMITH, C. M.B., L.R.C.P., has been appointed Resident Medical Officer to the Metropolitan Free Hospital, Devonshire-square, vice T. Fairbank, M.D., resigned.
 THORP, H. J., L.R.C.P.Ed., has been appointed Public Vaccinator for the St. Saviour's District of the St. Saviour's Union, Southwark, vice E. Hibberd, M.D., resigned.

PROVINCIAL.

CLEMENTS, G., M.R.C.S.E., has been appointed Senior House-Surgeon to the Royal Infirmary and Dispensary, Manchester, vice G. E. Walker, M.R.C.S.E., whose term of office has expired.
 DOUDNEY, Mr. E., has been appointed Assistant House-Surgeon to the Kent and Canterbury Hospital, vice G. W. Rigden, appointed House-Surgeon to the Tamerton and Somerset Hospital.
 ARMISTEAD, J. W., M.R.C.S.E., has been appointed Resident Assistant Medical Officer to the Leeds Public Dispensary, vice T. H. Haigh, M.R.C.S.E., resigned.
 FENNEL, T., M.R.C.S.E., has been elected Physicians' Assistant at the Royal Infirmary and Dispensary, Manchester, vice S. J. Hulme, M.R.C.S.E., deceased.
 WOODCOCK, J. R., M.R.C.S.E., has been appointed Junior House-Surgeon to the Royal Infirmary and Dispensary, Manchester, vice Clements, promoted.
 VEITCH, W. Y., L.R.C.P., L.R.C.S.Ed., has been elected House-Surgeon to the North Riding Infirmary, Middlesborough, vice J. Ellerton, M.D., appointed Surgeon to the same institution.
 WEAVER, J., L.R.C.P.Ed., has been appointed Surgeon to the Staffordshire County Police for the Districts of Longton and Fenton, vice S. P. Goddard, M.D., deceased.

IRELAND.

WILDE, Sir W. R., L.K.Q.C.P.I., has been appointed a Vice-President of the Royal Irish Academy.
 FELTON, T., M.D., has been elected Medical Officer and Public Vaccinator for the Saintfield Dispensary District of the Lisburn Union, vice C. K. Breeze, M.R.C.S.E., resigned.
 MCGLOIN, P. F., M.D., has been elected Medical Officer and Public Vaccinator for the Aclare Dispensary District of the Tobercurry Union, County Sligo.
 MURRAY, T. S., L.K.Q.C.P.I., has been elected Public Vaccinator for the Tobercurry Dispensary District, and Medical Officer to the Workhouse of the Tobercurry Union, vice J. M. McCarthy, M.D., deceased.
 O'DONNELL, T. B., L.K.Q.C.P.I., has been elected Medical Officer and Public Vaccinator for the Kiltrush Dispensary District of the Kiltrush Union, vice T. B. Elliott, M.D., resigned.
 FULTON THOS. M.D., L.R.C.S.Ed., has been appointed Medical Officer to the Saintfield Dispensary district of the Lisburn Union, vice Dr. Breeze, resigned.

Births, Deaths, and Marriages.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

BIRTHS—LONDON.

MACANN.—On the 5th inst., at King-street, Portman-square, the wife of Arthur B. Macann, M.R.C.S.E., of a son.
 DAVIDSON.—On April 7, at 8, Devonshire-place, Wandsworth-road, the wife of C. M. Davidson, M.R.C.S.E., L.S.A., of a son.
 HARVEY.—On April 15, at 5, Avenue-villas, Belsize-park, N.W., the wife of F. Harvey, Staff Surgeon R.N., of a son.
 HICKMAN.—On April 11, at 1, Dorset-square, the wife of W. Hickman, M.B., F.R.C.S., of a son.
 WATTS.—On April 13, at 23, Westbourne-park-terrace, the wife of A. J. Watts, L.R.C.P.Edin., of a son.
 HARVEY.—On the 7th inst., at Grosvenor-street, Grosvenor-square, the wife of John Harvey, M.D., of a son.
 BUCHANAN.—On the 7th inst., the wife of George Buchanan, M.D., of Harley-street, of a daughter.

PROVINCIAL.

FELCE.—On the 6th inst., at Southgate, Launceston, the wife of Stamford Felce, L.R.C.P.Ed., of a son.
 LANGFORD.—On April 14, at Knackers-knowle, Devon, the wife of E. C. Langford, M.R.C.S.E., of a son.
 MASON.—On April 14, at Woolwich, the wife of R. Mason, F.R.C.S., of a daughter.
 NOYES.—On April 14, at Lee, Kent, the wife of H. G. Noyes, M.D., M.R.C.P.Lond., of a son.
 ROSE.—On February 22, at King William's Town, Cape of Good Hope, the wife of H. J. Rose, Staff Assistant-Surgeon, prematurely, of a daughter.
 SHEPPARD.—On April 7, at Ashford, Kent, the wife of William Sheppard, M.R.C.S.E., of a daughter.

SCOTLAND.

COWAN.—On the 6th inst., at Achenoshan, the wife of J. B. Cowan, M.D., of a son.

MARRIAGES.—ENGLAND.

CROSBY.—PLATT.—On April 12, at St. Mary's, Oldham, William Crosby, M.R.C.S., to Elizabeth, daughter of the late H. Platt, Esq.
 WINTLE.—MACKINLAY.—On April 12, at St. Barnabas, West Kensington, R. P. Wintle, M.R.C.S.E., to Catherine, youngest daughter of the late John Mackinlay, M.R.C.S.

SCOTLAND.

WILSON—WOTHERSPON.—On April 11, at 124, Blythwood-terrace, Glasgow, W. A. Wilson, M.D., C.M., to Jeannie Erskine, daughter of John Wotherspoon, Esq.

DEATHS.—LONDON.

HARRISON, G., F.R.C.S., of 65, Grosvenor-street, on April 12, aged 60.
 HODGES, F. S., M.R.C.S., at 84, Brompton-road, April 12, aged 43.
 KELSON.—On the 15th inst., at Shacklewell-lane, West Hackney, William Mortimer, eldest son of George Kelson, Surgeon, late of Sevenoaks, Kent, aged 33.
 ROSS.—On the 20th Feb., at Trevandrum, Trevancore, South India, Hamilton O'Haboran, the second son of Hamilton M. Ross, M.D., Physician to his Highness Maha Rajah of Travancore, aged 7 months and 10 days.
 SEYMOUR, E. J., M.D., F.R.C.P.Lond., at 13, Charles-street, Berkeley-square, on April 16, aged 70.
 SLOPER.—On the 7th inst., Mr. Thomas Gyde Bott Sloper, Assistant to Dr. Odling, Professor of Chemistry at St. Bartholomew's Hospital.

SCOTLAND.

LIVINGSTONE.—On the 15th inst., at Amulree, Perthshire, Mr. John Livingstone, Medical Student, Edinburgh, aged 22.

PROVINCIAL.

BOGG, JOHN, M.R.C.S., at Louth, Lincolnshire, on April 15, aged 66.
 BRATHWAITE, W., M.R.C.S., at Stroke Damerel, on April 9.
 MAY, W. H., M.R.C.S., at St. Martin's, Leicester, on April 9.
 PARSONS, W. A., M.R.C.S., at Leamington, on April 4, aged 65.
 SCOTT, W., M.D., at Greenwich, on April 12, aged 41.
 ALLARDOYE.—On the 6th inst., J. Allardoye, M.D., of Cheltenham, Surgeon on half-pay 5th Garrison Battalion, aged 84.
 HARLAND, WM., M.D., of Scarborough, on the 6th inst., aged 79.

POOR-LAW MEDICAL SERVICE.—VACANCIES.

ENGLAND.

Wolverhampton Union.—Second District; area 807; population 12,800; salary £54 8s. per annum.
 Bridgewater Union.—Chilton Polden District; salary £50.
 Bath Union.—Abergwessin District; area 68,480; population 3784; salary £42.
 Leeds Sanitary Inspector.—Salary £500 a year; election May 9.
 West London Hospital, Hammersmith.—Resident Surgeon.
 Isle of Thanet Union.—Medical Officer; salary £145; area 15,797; population 3479.
 Tickhurst Union.—Salhurst District; salary £50; area 10,082; population 2878.

IRELAND.

Westport Union.—Islandeedy Dispensary; election May 4; salary £75; vaccination and registration fees about £25.
 Longford Union.—Drumshill Dispensary; salary £80 and fees; election May 3.
 Mountmellick Union.—Mountrath Fever Hospital; salary £40.
 Oxtelston Union.—Crossakeel Dispensary; election May 3; no salary stated.
 Team Union.—Dunmore Dispensary; salary £100 and fees.

WEEKLY METEOROLOGICAL REPORT FOR THE WEEK ENDING APRIL 21st, 1866.

By J. H. STEWARD, Strand, and Cornhill, London.

April, 1866.	Barometer reading reduced to 32 degrees.	Thermometer.		Dry bulb.	Wet bulb.	Wind.		Rain.	Remarks.

Original Communications.

ON THE TREATMENT OF GOUT BY HYDROCHLORIC ACID.

A Clinical Lecture delivered in the Adelaide Hospital, April 11, 1866.

By JAMES F. DUNCAN, M.D., F.C.P., &c.

DR. GARROD'S VIEWS ON GOUT—INSUFFICIENCY OF HIS
THEORY—PROPOSED EXPLANATION OF THE COURSE
OF MORBID ACTION—ILLUSTRATIVE CASE.

GENTLEMEN,—The presence of some cases of gout and acute rheumatism at one time in our wards, led me at the last lecture to bring under your notice the principal points of resemblance and contrast presented by these two very interesting and important diseases. You may remember that I stated they were both marked by high fever, by a painful affection of the joints, and by a tendency to sudden changes of situation in the seat of pain. They both seem to depend upon the presence of a peculiar principle in the blood, which, whether naturally there in a state of health or not, deserves from its augmented quantity during the period of the paroxysm to be regarded as a morbid product and a sort of animal poison. This principle, though differing in the two diseases, agrees in this, that it possesses in each the properties of an acid. I hope to show you in the course of these observations that its production in each instance depends upon imperfect oxidation of the blood, and more or less impaired nervous energy as the cause of that imperfect oxidation. I need scarcely remind you that the acid which is thus accumulated in the gouty subject is the lithic or uric, and in the rheumatic the lactic. The presence of lithic acid in gout is not a mere matter of conjecture. The labours of Dr. Garrod have incontestably established the truth of a position which was previously felt to be true, though physiologists had failed to reduce it to demonstration. With regard to the other it remains a matter of inference only, though I think no one can doubt, after the experiments made by Dr. Richardson of London, that lactic acid is the efficient cause of the peculiar phenomena of acute rheumatism. In these experiments he endeavoured to establish synthetically the soundness of the views previously entertained as a matter of theory; and to my mind he appears completely to have succeeded in supplying the deficiency in the chain of evidence that arises from the failure of the attempts made by organic chemistry to separate lactic acid from the blood of rheumatic patients.

Assuming for the present as a matter of fact that the blood in gout is charged with lithic acid to an extent far beyond the natural standard of health, and in rheumatism with lactic acid, let me proceed very briefly to state to you my views as to the production of these different conditions, and the principles of the treatment you have seen me use for their mitigation and removal.*

I shall not occupy your time with any detail as to the

various theories which have been held by different authors on this subject, as you will find them sufficiently explained in the text books in common use. I shall only advert to that broached by Dr. Garrod in his recent work, which may justly be regarded as the standard authority of the present day. And while I feel that in venturing to differ from one enjoying so high a position as a practical physician and a man of science, I am taking a bold step, I feel at the same time that I would be wanting in my duty to you if I did not put you in possession of the opinions I have been led to form after careful study upon this subject, and of some of the facts upon which those opinions have been founded.

Dr. Garrod looks upon the kidney as an organ whose function is merely to separate from the blood certain principles which exist in that fluid already, and which having served their purpose in the economy, are no longer necessary to be retained, and which, if retained, would prove positively injurious. He does not consider that the kidney manufactures by its own inherent power these principles out of the blood, but that they are already in the blood in the form in which they come to be eliminated, and only require to be separated from the fluid in which they are dissolved by a sort of elective affinity. In other words, that the function of the kidney is one of excretion and not of secretion. Urea and uric acid are two of these principles.

Now, in reference to these two products, he considers that they have no necessary relation to each other, and that the power of excreting one may be maintained in full energy, while that of excreting the other may be diminished or arrested. In gout he considers that the excretion of lithic acid is impaired just as the excretion of urea is impaired in Bright's disease. The latter position is too well known to be disputed, and a careful examination of the cases in Dr. Garrod's work establishes beyond all question that the quantity of lithic acid excreted during the paroxysm of gout is, as a matter of fact, greatly diminished. The consequence is that the lithic acid, if its formation in the blood continues to take place, must rapidly accumulate in that fluid. Accumulating here it acts as a poison, and gives rise to all those symptoms which characterise the phenomena of a gouty paroxysm. (See Dr. Garrod's work, p. 339). "Gout," to use his own words, "would thus appear partly to depend on a loss of power (temporary or permanent) of the acid excreting function of the kidneys; the premonitory symptoms, and those also which constitute the paroxysm arising from an excess of this acid in the blood, and from the effort to expel the materies morbi from the system. Any undue formation of this compound would favour the occurrence of the disease; and hence the connexion between gout and uric acid, gravel, and calculi; and also the influence of high living, wine, porter, want of exercise, &c., in inducing it."

The objection I take to this explanation is this, that while it may be sufficient to account for the symptoms after the paroxysm is formed, it gives us no help to explain the cause of the loss of that uric acid excreting function in the first instance.

Let me now proceed to set before you the views I have been led to form on this matter. Adopting the idea broached by Liebig that the protein compounds of the body in the disintegration of the effete tissues are converted through the agency of oxygen, first into uric acid and then into urea, as shown in the diagram (see below), it will follow that if by any circumstance the necessary degree of oxidation be not reached, the metamorphosis will be arrested in the state of uric acid, and this substance, which ought to be met with in very small quantity, will be proportionately augmented. I take it for granted that the removal of the nitrogenous compounds from the body after they have served their purpose in the economy, is naturally and principally effected in the form of urea rather than of uric acid, both on account of the much greater quantity of urea habitually found in the urine and from its greater solubility.

* See a paper on this subject in the Dublin Quarterly Journal for May, 1865.

$$\begin{array}{r}
 1 \text{ at protein} = 48 + 6 + 36 + 14 \\
 91 \text{ at oxygen} =
 \end{array}
 \left. \vphantom{\begin{array}{r} 1 \text{ at protein} \\ 91 \text{ at oxygen} \end{array}} \right\} = \left\{ \begin{array}{r}
 \begin{array}{r}
 c. \quad n. \quad h. \quad o. \\
 15 + 6 + 6 + 9 = 1\frac{1}{2} \text{ at uric acid.} \\
 33 = 66 = 33 \text{ at carbonic acid.} \\
 = 30 = 30 \text{ water.}
 \end{array}
 \end{array} \right.$$

$$\begin{array}{r}
 48 + 6 + 36 + 105 \\
 10 + 4 + 4 + 4 \\
 4 + 4 + 8 + 4 = 2 \text{ at urea.} \\
 6 + = 12 = 6 \text{ carbonic acid.} \\
 10 + 4 + 8 + 16 \\
 10 + 4 + 8 + 16
 \end{array}$$

But it is not only from the disintegration of the albuminous tissues that uric acid may be thus formed. It is obvious that precisely the same changes may take place in the primary assimilation of protein compounds used as food, and I need scarcely tell you that the great majority of animal substances used for food are really but modifications of the elementary compound which has been designated protein. We have hence naturally two sources of uric acid in the system, one which may be considered almost constant in its amount, arising from the metamorphosis of tissue undergoing disintegration, and another variable quantity arising from the greater or less amount of nitrogenized food consumed by each individual. And in proof of this I have only to refer you to the diagram on the wall, which shows the marked influence which diet has upon the function of the kidney, augmenting both the urea and the uric acid when the food is exclusively animal, diminishing them when it is partly animal and partly vegetable, diminishing them still more when it is exclusively vegetable, and making them least of all when a diet is selected from which every atom of nitrogen has been carefully excluded.

Now, I need scarcely remind you that gouty patients are met with principally among that class of society who feed well, consume much animal food of the richest and most nourishing kinds. Here, then, we have one source of the production of uric acid in excess. Not necessarily I admit, for if the person who indulges in food of this description takes much exercise in the open air, and pursues some laborious occupation to work off the nutriment as rapidly as it is taken, the balance between the functions may be preserved and no harm follow. But if, on the contrary, he be a person of studious and sedentary habits, who takes little exercise and is not much in the open air—in whom, in fact, the function of respiration is only kept up at an average amount, it is plain that the oxidation in the lungs being insufficient to convert all the uric acid which is formed into urea, an accumulation must take place, to prove a source of subsequent discomfort and disease. But this is not the only source of mischief in these cases. I conceive that one of the causes of the increased production of uric acid is to be found in the imperfect or insufficient manner in which the function of respiration is performed, owing to the disturbed state of the digestive system. This is a point altogether overlooked by Dr. Garrod, which, if there be any truth in the chemistry of vital processes, must be regarded as of the greatest importance. You all know that the pneumogastric nerve is distributed to the lungs and to the digestive organs, and that its integrity is equally necessary for the healthy performance of both sets of functions. This being so, it is not unreasonable to suppose that whatever tends to concentrate unduly the nervous energy of this nerve in one of these two directions must *pro tanto* interfere with its efficiency in the discharge of its functions in the other. If the alimentary canal be overloaded at any time with food beyond what the gastric juice can conveniently assimilate, and still more if that food be of an indigestible quality, causing the process of digestion to be protracted and difficult, the function of respiration must suffer. And here I would remark that the only test of the efficiency with which the process of respiration is effected, is the amount of carbonic acid exhaled in a given time. It is quite

possible for the mere act of respiration to be accelerated, while the proper duty of the lungs is not performed up to the standard of health. The chemical changes in the blood may not be consummated notwithstanding the increase in the frequency of the acts of inspiration and expiration. Indeed, so far is this the case, that that very increase may be only Nature's effort to compensate for defective results, just as we know that the heart, when weakened by disease, endeavours to make up for its impaired energy by a quicker circulation.

I am not aware that any experiments have been made to set this question at rest by ascertaining the amount of carbonic acid exhaled by the lungs when the stomach is loaded and when it is empty; but it could easily be accomplished, and I have no doubt what the result would prove. It is an ascertained fact, that when the body is exposed to a high temperature, as in a warm climate, the quantity of carbon thrown off by the lungs is diminished, and this is one of the causes of hepatic disease in tropical districts, because a greater amount of this substance is left for removal in the shape of bile in consequence of this diminished exhalation of carbonic acid; and the same thing happens as a consequence of using alcohol—a circumstance which, taken with what has been said, may help to explain the production of gout in persons of intemperate habits, especially those who use alcoholic liquors which contain various forms of vegetable extracts, because the latter disturb the function of digestion more than others that are only so many kinds of dilute alcohol. Now, it is scarcely necessary for me to prove that the function of digestion is very materially disturbed in every case of gout. Sometimes this disturbance seems to be merely the result of impaired nervous energy which shows itself in the secretion of an inferior quality of gastric juice, so that persons of abstemious habits are often martyrs to a disease that is commonly understood to be caused by indulging in the pleasures of the table, but which, in their case, owns no such discreditable origin. But most frequently the fault is not in the organs that suffer, but in the bad usage they are exposed to, more work being thrown upon them in the quantity and quality of food taken than they are capable of performing. If proof of this position were needed, we have it in the foul breath, the loaded tongue, the nausea and sense of weight in the stomach, the flatulence that most gouty patients are subject to, and still more in the common interval observed to take place between the time at which an error of diet has been committed and the development of the actual paroxysm.

You will now, I dare say, easily be able to catch the views I have been led to entertain regarding this affection: a disordered digestion is the primum mobile of the whole train of morbid phenomena. This leads to imperfect performance of the function of respiration; this, again, to imperfect oxidation of the protein compounds in the blood, whether of primary or secondary origin; and the consequent accumulation of these products in the form of uric acid. This accumulation again leads to the special symptoms of the gouty paroxysm, general disturbance of the entire system, suspension of the function of the kidney, and further augmentation of the *materies morbi* in the blood by its non-elimination at the proper channel.

This, of course, is but a very imperfect sketch of the

subject, but the time at our disposal does not admit of my entering upon the discussion more fully at present.

Now for the treatment you have seen me in the habit of pursuing in these cases. It is simply the free use of hydrochloric acid, either alone or differently combined. The principle upon which I suppose it to act is not that it supplies oxygen to the uric acid to convert it into urea, but that it increases the digestive power of the gastric juice, enabling the stomach more readily and effectively to accomplish the process of assimilation, and so indirectly increasing the nervous energy so as to effect more perfectly the vital changes in the chemical constitution of the molecules of the blood, which are necessary to prevent the occurrence of this disease.

It is scarcely necessary for me to tell you that this remedy is entirely at variance with all the plans of treatment hitherto in use for the cure of gout. Alkalies, in some form or other, to neutralize the lithic acid, and especially those alkalies or alkaline earths, which, entering into combination with this acid, will make salts of ready solubility, have been the fundamental supports of every plan that has met the approval of the profession. Other remedies have been used, but they were either ancillary to alkalies as the sheet anchor, or were employed for some special purpose. I do not put forward the hydrochloric acid as a specific to be used under all circumstances and in every stage of the disease, neither would I mean thereby to exclude the use of such other agents as may be obviously demanded to meet special contingencies. All that I contend for is, that it seems to me to act more directly upon the primary cause of the disease and to hold out greater prospect of effecting a real cure than any antacid remedy I know of. I shall now give you the particulars of the last case we have had under our care, briefly condensing the notes made by my clinical clerk, Mr. Reilly, not to exhaust your patience by too great a detail. I do so with the more pleasure because of its undoubted character as a true case of gout, of the severity of the symptoms, and of the fact that he was put upon the use of the acid from the first, which gave him immediate and permanent relief.

George H., an Irishman by birth, who had passed most of his life in England, was admitted into the Adelaide Hospital, Dublin, March 8, 1866. He was thirty-seven years of age, by occupation a land-surveyor and leveller, and as such constantly exposed to the weather. He always lived well, eating meat and cheese at least three times a day, and drank pretty freely, preferring ale to porter or spirits. He was quite free from disease until eight years previously, when, in consequence of a severe wetting, he was laid up for four weeks with swelled ankles, the joints of his toes especially, the great toes being also affected. He had three subsequent seizures, in which his feet and ankles alone were engaged. These occurred at intervals of three months; his knees afterwards became implicated, and later his wrists and fingers. Formerly he was accustomed to have an attack four times a year, but latterly they had become much more frequent, supervening upon the least exposure to cold or damp. The joints were always of a bright red colour, and afterwards desquamated. The family history was perfectly healthy, and his digestive powers appeared unimpaired. Five days before his admission, in consequence of a wetting, he was again attacked, when all his joints were more or less affected, his ankles, toes, wrists, and fingers being particularly implicated. These parts were hot, red, and swollen, and very sensitive. He had to be carried up stairs to bed, being unable to stir either hand or foot; he was sweating profusely; his urine scanty and acid; his tongue white and furred; the bowels open; his pulse 90. Large tophi existed on each knuckle, which were very red and inflamed. Several well-marked concretions were observable on each ear, but they were not painful or tender to the touch.

R. Acid. hydrochloric. dil. ʒi.s.

Sp. chloroformi, ʒii.

Tinct. colchici, ʒi.

Infus. cascariil. ad ʒviii.

Smect. ʒi. ʒiiss. horis sing.

March 9th: Much better; countenance clearer, less expressive of suffering; slept well; pains much diminished, particularly in the ankles; pulse 72.

10th: Pains in wrist and fingers better; sweating continues.

11th: Still improving; quickly regaining the use of his wrist and fingers; no pain in the lower extremities, except on attempting to move them.

14th: All his joints free from pain; able to move without inconvenience, except from weakness in his ankles; sweating diminished; tophi uninflamed and getting smaller, though still slightly tender; pulse 62; tongue clean; appetite good; urine alkaline. Ointment of iodide of potass to be applied to tophi; continue his mixture.

24th: Quite well; able to walk and write with his usual ease; complained of weakness. Ordered quinine mixture, the hydrochloric acid being stopped.

25th: Pains again troublesome; bowels confined; tongue red. Omit quinine mixture; to have an oil draught.

27th: Left the hospital at his own request to follow his occupation.

This case did not appear to require any preliminary treatment before having recourse to the remedy which I here recommended. It was essentially one in which the vital energy was depressed where a tonic line of treatment was particularly called for, so far as I have yet had the opportunity of forming an opinion, it is in cases of this class it is most eminently useful. Some persons may suppose that the improvement was due to the colchicum which, you know, is generally considered a specific in gout and which was combined with it. But without attempting to undervalue the utility of this much vaunted remedy, my experience from other cases in which the acid was tried alone leads me to conclude that a very important part of the benefit is to be attributed to the acid, and having already shown this in other cases when the acid was tried by itself, some of which were recently in the hospital, I do not see why I should throw overboard a combination of two useful medicines in a suitable case merely to establish the reputation of one of them, which happens to be less generally known. I also added spirit of chloroform as a carminative to check the tendency to the generation of flatuæ in the intestinal tract, and infusion of cascariilla as a general tonic. The only inconvenience he experienced from the treatment was a slight diarrhoea on the 20th of the month, which did not require a change of the medicine, but merely a reduction in the dose. Any of you who saw the helpless condition of the patient on his admission, the expression of pain depicted on his countenance, and the sensitiveness with which he shrunk from even an approach to the bed-clothes near the inflamed parts, cannot fail to have been struck at the marked and immediate improvement under the treatment, and especially at the change in the appearance of the tophi from what they were at first, instead of being red and swollen they diminished in size, and lost all that angry look that they presented on admission. In conclusion, this I can say with confidence, the theory I now broach may be wrong, but the treatment is pre-eminently safe and beneficial.

NOTES OF

SOME CASES IN WHICH DR. RICHARDSON'S METHOD OF INDUCING LOCAL ANÆSTHESIA WAS EMPLOYED.

By WILLIAM MacCORMAC, M.A., M.D., F.R.C.S.I.,
SURGEON, BELFAST GENERAL HOSPITAL.

THE great rapidity with which Dr. Richardson's method of inducing local anesthesia has been adopted is the best assurance its inventor can possess of its practical utility. Nevertheless, it may not be without interest to record the nature of the cases in which it has been employed in the Belfast General Hospital, and the results which attended its use. The great demand for the apparatus caused some delay in procuring it and it was only on the 6th

April that I was first able to test the efficacy of the method.

The first case was an aggravated one of onychia maligna of the great toe, in a girl 21 years of age, and the operation I performed was that ascribed to Dupuytren, which consists in cutting out the nail with the soft parts around it, so as entirely to excise the matrix. No more painful operation, considering its extent, could be required, and none was better calculated to test the efficiency of Dr. Richardson's method. The incisions requisite are three in number, and it is necessary to cut deeply into the parts around the exquisitely sensitive matrix. The ether spray was directed for seventy-five seconds against the toe. In fifty seconds it suddenly blanched all over. The patient's eyes were covered, and the operation completed without any sign of pain being shown. The girl was all the time clasping in her hands the arm of the nurse, who stated that she did not feel her arm more tightly compressed during the cutting of the toe than it was before or after. There was no after-pain on reaction, and the patient stated that she felt the cold, but nothing else.

The next case, also one of onychia maligna in the great toe of a girl, and operated upon the same morning, was quite as striking. The ether spray was applied for forty seconds only. A napkin having been laid over the eyes, the same operation was performed as in the preceding case. The patient evidently suffered no pain, for during all the time of the operation, and until she was allowed to rise and look at her toe, which meanwhile had been dressed with wet lint and a bandage, she continued to call out, "*hurry and do it.*" When she saw the operation was completed, having been previously unaware that it had been even commenced, she began to laugh, and said she felt nothing but the cold, and that it was not painful. She could hardly believe that a knife had been used. No after-pain was felt on the recovery by the part of its normal temperature, nor was there any hæmorrhage. Both patients were directed to bathe their toes for some time after the operation in cold water.

I subsequently performed a similar operation in a third case of onychia of the great toe. The patient said she felt a slight "jagging" sensation while the knife was being used. It is not necessary to enter into further details about it.

The next case in which I tried local anæsthesia likewise presents features of interest:—

Maria Lyons, a mill-worker, was brought to hospital, April 11th, with a severe laceration of the forefinger, necessitating its removal at the metacarpophalangeal joint. For many years she had been subject to cough and bad breathing, and now she had difficult wheezing respiration, her shoulders being raised towards her ears as she drew her breath. Her cheeks were of a dusky red hue, showing the insufficient aëration of her blood. In addition she was very much excited. The case was one in which the administration of chloroform would have been attended with considerable risk, if not contraindicated altogether. Local anæsthesia was accordingly induced with common ether, no absolute ether being in the hospital at the time. Blanching of the skin took place in two minutes and a half, and the finger was removed by a double flap operation. One artery required ligature, and one suture was inserted. The head of the metacarpal bone was not removed. The rest of the hand was protected during the application of the spray by lint wrapped around it. The woman stated, that, until afterwards informed, she was quite unaware of any operation having been performed, that she suffered no pain, and that the cold of the spray did not feel unpleasant. The after progress of the case has been perfectly satisfactory. No pain occurred on reaction, there was no secondary hæmorrhage, and the wound is healing quickly.

On the 12th April, James Martin, an intelligent mechanic, 19 years of age, applied to hospital with a laceration of the third and little fingers of the left hand. In the latter there was a laceration, about an inch in length,

but the former was so much injured as to require amputation of the distal phalanx. The ether spray was directed upon it, and produced the desired effect in forty seconds. A dorsal flap was then formed, sufficient to cover the end of the finger, and the bone divided with forceps just above the last joint. One suture was inserted, which he felt slightly while the needle was being passed through the palmar margin of the wound, owing to the spray being insufficiently applied to that point. Martin stated afterwards that he felt no pain, except that before mentioned, and that although he distinctly heard the bone snapping when divided by the bone forceps, he did not feel it. No pain was experienced on reaction, and the patient yesterday informed me he felt much more annoyance from the laceration of the little finger than he did from the finger in which the amputation had been performed.

The following day I amputated the distal phalanx from the third finger of a girl with equally satisfactory results.

The next case was that of a policeman, from whom I had some time previously removed an external pile by scissors. He complained of great pain at the time, and for two or three hours afterwards, amounting to agony. On the 14th April, after applying the spray for thirty seconds, I cut off with the scissors a small external pile from this patient. He submitted himself with fear and trembling, and could hardly believe the evidence of his senses when he found the operation had been completed without his having experienced pain.

My colleague, Dr. Murney, has not as yet tried this method in many cases, but a few days since he removed a large number of warts from the glans penis and prepuce without the patient experiencing pain, and the proceeding was much facilitated by the absence of that copious hæmorrhage which usually complicates such operations. He also painlessly divided the skin over a piece of necrosed bone in the leg which required extraction.

These cases would, I think, establish, were any further evidence necessary, the great usefulness and facility of application of Dr. Richardson's method. The principle may not be new, but Dr. Richardson may justly claim priority for an invention by which the sensibility of a part may be temporarily destroyed with certainty without injuring its vitality, or interfering with any process of repair which may afterwards be set up in it.

In the first volume of the fifth edition of Vidal's "*Traité de Pathologie Externe*" it is mentioned, that during a discussion at the Imperial Academy of Medicine, on the value of Dr. Hardy's local chloroform apparatus, M. Alphonse Guérard announced that he had obtained similar results by dropping ether upon the part he wished to anæsthetise, and instantly evaporating it by means of a strong current of air. He states also that, in his opinion, when air charged with anæsthetic vapour was directed upon a part, insensibility was produced by the chilling of the part. M. Giraldes mentions, in the second volume of the "*Nouveau Dictionnaire de Médecine et de Chirurgie Pratiques*," that whenever local anæsthesia of a portion of the body is desirable, that result may be obtained by directing upon it a stream of ether or chloroform pulverised in one of the many instruments used for that purpose.

These modes were, however, confessedly very uncertain and imperfect, and it was reserved for Dr. Richardson's ingenuity to devise the simple and efficient means of producing local anæsthesia, which goes by his name.

It is certainly an inestimable boon that a means has been provided by which such operations as I have detailed can be performed without pain, without submitting the patient to the risk of death from chloroform, or the other inconveniences which often follow its administration. I have no doubt, too, that by a multiplication of the number of jets, this method might prove applicable to some of the larger amputations.

The ether I used was as nearly absolute as possible, and was prepared for me with great care by Messrs. Wheeler and Whitaker of Belfast.

THE APPARENT CAUSES OF FEVER AND CHOLERA.

By CHARLES F. MOORE, M.D., F.R.C.S.I.,

ONE OF THE PHYSICIANS TO CORK-STREET FEVER HOSPITAL AND HOUSE OF RECOVERY, ETC.

(Continued from page 145.)

THERE appears no doubt that the type of fever varies in its symptoms, and in the remedies, stimulants, and diet most suited to it, in some considerable degree of accordance with the circumstances or apparent causes under which the illness commenced.

In this way a case presenting the characters of marsh malaria, and having apparently arisen in a district of a swampy nature, or in a locality where exhalations from decaying vegetable and animal matters existed, will most likely present symptoms in accordance with what we might expect under the circumstances, although the predominating symptoms may be those of typhus fever, which may have been superadded by exposure to the causes to which we attribute the latter disease.

I was led to consider these differences in cases of fever in Ireland by observing the different effects of tea on cases occurring in city and in country practice.

In the former class tea is constantly taken with relish and benefit, whereas I have seen it refused, or, if taken, undoubtedly produce increased tremors, debility, and in one instance it was apparently the cause of a relapse. As also corroborative of this difference, I found bitters and stimulants free, or nearly free, from any form of sugar, relished, and their use attended with evident benefit; whereas stimulants or articles of food containing sugar were generally refused in cases arising in malarious localities. Every physician has found the value of bitter tonics to vary in fever cases, the variation arising apparently from the circumstances under which the illness arose. A very great difficulty, no doubt, attends the actual demonstration of the cause of fever, and my object in these papers is to endeavour to bring under notice the conditions under which disease originated, placing as many facts together as possible, in the hope that some light may be thrown upon questions of great importance, either by the results of what I have seen, or by inducing others, whose powers of observation and induction or opportunities of observing are greater than my own, to publish the results of their experience.

Without for a moment wishing to take from the value of Dr. Barker's researches into the effects of exposure to cesspool air, it appears to me that there is necessarily an imperfection in the reasoning that because, in the instance he has given, no communicable disorder was induced, we should necessarily say that exposure to the foul air, under all conditions, would not be followed by communicable disorder. It might as well be said that, because a number of persons can live together in an atmosphere supportable by them without injury, under ordinary circumstances, that they will necessarily always escape its effects, or that another person coming, it may be from a distance, will also escape any bad effects from exposure to an atmosphere which is at first insupportable by him, but which others bear apparently with impunity.

It is now several years since the late Dr. Andrew Buchanan, in speaking of the fever which has so often prevailed with great severity in Glasgow, pointed out in his lectures the circumstance to which I now allude, adding that the new arrival from the country seized with fever on his sojourning in the crowded and unhealthy tenements of the lower classes in that city became, as it were, in his turn, the source of fever which spread from him to those who had apparently borne the unhealthy conditions by which they were surrounded with impunity.

Let us for a moment inquire whether the condition of the lower orders in crowded or unhealthy localities in town or country is as sound as might be supposed, were we

to judge from the degree of immunity enjoyed by those classes. That theirs is not a state of health, and that the poor countryman who too often is blamed for the fever which he is supposed to bring into the filthy or overcrowded city tenement is, I think, shown by other circumstances, some of which are as follows:—If one of the class to which I allude gets a severe wetting, or is long exposed to cold, exhaustion, or privation under fatigue, then very generally we have an attack of fever produced, varying in its type (as to being typhus or typhoid) according to the circumstances in which the individual had been placed previously.

It appears to me, undoubtedly also, that cholera, diarrhoea, dysentery, diphtheria, and some other forms of disease, in like manner owe their origin to the presence of some like exciting cause, acting in unison with an atmospheric predisposition, if you will, or, in other words, with some agency hitherto beyond our means of perception, but acting at times in producing fevers varying in gravity, or at other periods producing plague, cholera, dysentery, or other form of disease, whose tendency and mode of progress has more or less of a nature in common with other diseases of the same class.

Corroborative of the views of Dr. A. Buchanan, which I have myself been led from experience to confirm, I find Smoler has observed removal from the country to the town as the most constant cause of sporadic fever, and he ascribes its effect to the bad sanitary arrangements of large cities. He observed at Prague* that all the typhus cases came from recently inundated districts. In my own practice, I have found that unless the locality or part of a dwelling in which fever commences be in an extremely unfavourable condition, or unless the person be exposed to the influence of an unhealthy locality for a very long period, as months or even years, the exposure may not culminate in the production of fever, unless some other powerful agency comes into operation, such as a severe wetting, cold, &c., as above alluded to; or if the individual, whose system may be, as it were, charged with paludal emanations, such as so often exist in damp and unhealthy country dwellings, goes to reside in a crowded town, and gets an attack of fever, caused, as he thinks, by the town influences, whereas his town friends assert that he imported the sickness with him, the truth often lies between both statements, and that the case is really owing to the fact that the germ of disease, existing in his constitution from the malaria in the country, was called into activity by removal to town, and the depressing influence of the air of a crowded and unhealthy dwelling there.

There can be no greater error than the removal of bodies of men from quarters likely to engender disease to others certain to further the development of the same.

Captain Burton, the distinguished traveller, spoke to me of the injurious consequences which always followed the removal of troops from the West Indies to the West Coast of Africa; and it is most lamentable to observe the want of judgment too often displayed by those whose duties it should be to protect our soldiers and sailors from the dire influences of the worst of climates, instead of obliging them to go from bad to worse, from some old plan of routine, or from some fancied ideas of economy. It would be easy to prove that not only is such a course unjustifiable on the score of humanity, but also of economy. Indeed, the variety of profitable employment, yearly opening up new fields for enterprise and labour, tend to lessen materially the number of the unemployed, especially of the class from which our soldiers and sailors are generally obtained, and if better care is not taken of these forces the difficulty of filling up vacancies will yearly increase.

Further evidence on the necessity of a judicious "roster" of duty for men whose constitutions have been debilitated by exposure to malaria in one climate is contained in the last Army Report, from which I take the following:—"All West Indian soldiers suffer greatly from

* New Sydenham Society's Year-Book, 1863.

change of climate. Many, if not most, of the 4th West India Regiment suffered more from the effects of this climate (that of Africa) on their first arrival than white men would. Thus, the first detachment of the 4th West India Regiment landed on the Coast in August, 1863, and were at once attacked by fever and dysentery; before December of same year they had somewhat recovered (by no means wholly), and then were employed in the interior, the inevitable results of which, following so soon on constitutions lately shaken, told with most serious effect."

Everywhere a somewhat similar chain of events appears in the production of fever and allied diseases, whether it be in the malarious swamps of Africa, in the crowded cities of China, India, or America, or in those of Europe—namely, the constitutions of the earlier victims of disease are found to have been more or less debilitated by depressing agencies, illness is either at once developed, or it may in other cases require a subsequent exposure to other agencies to call forth its full development. Again, when once fever, cholera, or dysentery appears among human beings crowded together, the disease too often proves infectious, spreading with a fatality and rapidity commensurate with surrounding conditions.

It is often said that cholera shows an unaccountable predilection for particular localities, as, for instance, one side of a street, a particular part of a town, &c.; and the case of a house presenting appearances of comfort and cleanliness beyond that of other houses whose inmates may have escaped illness, is very probably cited to show that, as its inhabitants have been seized with cholera, cleanliness has nothing to say to the matter.

It is generally easy, in any given case, to ascertain on a close investigation into all the circumstances, that in some respect a loophole was left, so to speak, through which the disease gained access to the house or locality in question. I attended a case of well-marked cholera at Finglas in 1854.* The house in which the patient, a young woman of 23 years, lived, was otherwise clean, but not sufficiently ventilated, and a lad had already died of cholera in the same house; lastly, also, there was no mention of the source whence the water was supplied to this family. Four circumstances concurred in this case to explain the possible origin of the disease—namely, the existence of the epidemic in the locality, the previous death from the disease in the same house, the deficient ventilation, and possibly the quality of the water used. Any one of the latter three conditions might, I think, owing to the existence of cholera in the locality, have caused a predisposition to it.

Reserving for a future opportunity further remarks on the circumstances under which I have known cases of cholera to occur, I will conclude the present notice with some account of the conditions existing in and around dwellings in which fever has occurred in successive seasons and in different families.

I have within the last few days visited two families, in different rooms, but on the same floor, in fever. These two families occupy the second floor. I learned that persons have been in fever on the floor above them also recently, and twelve months since I understand fever had also existed in the same house. I observed also that the persons living in the storey below that in which the sick persons now lie do not allow the members of their own family to enter the apartments where the sick now are.

On examining the house in which these cases have occurred, not only this year, but also in previous seasons, I noted the following facts:—The house is dirty, the apartments are small, with low ceilings; at least one family lives in each room; however, in one small room I only found one man—he being in fever—and I cannot say whether "he takes in a lodger" or not. In the hall there are two or three rat-holes, evidently communicating with the sewer which appears to pass beneath it; in the small back yard, where is a latrine and ashpit, there is also an untrapped opening to the sewer; surrounding the

small yard are other yards, in which large heaps of manure are stored, and pigs, donkeys, and other animals are kept.

In this house, as is generally the case in the locality—the poorest part of the Coombe—there are some very poor persons, badly fed, badly clad, and frequently exposed to inclement weather.

(To be continued.)

Hospital Reports.

[The first report in the present number contains the conclusion of Dr. Hayden's case of "Thoracic Aneurism," and is continued from page 334. The second illustrates Dr. Lyons's views of "Tonsillitis," and his treatment of it. I have again to acknowledge the kindness of both these gentlemen in giving me the use of their private notes. The third illustrates Mr. Porter's treatment of several surgical affections. This portion of the report was written and kindly furnished by Dr. Foot.—T. W. BELCHER.]

MATER MISERICORDIÆ HOSPITAL.

CASE OF THORACIC ANEURISM.

(Under the care of Dr. HAYDEN.)

(Continued from page 334.)

March 25th: Passed a good night, and declared he felt better this morning; called to the nurse for his medicine at half-past six o'clock, and sat up in his bed to take it. Immediately on assuming this posture he complained of excruciating pain in the abdomen, cried out that he was dying, became deadly pale and much agitated, and died of syncope in about thirty minutes, the tumour having ceased to pulsate from the time he complained of pain till his death.

26th: *Post-mortem examination of body twenty-eight hours after death.*—Body well nourished and covered with a thick layer of subcutaneous fat. A large tumour, of the size and figure of the female breast, occupied the upper and anterior portion of the right side of the chest, extending from the clavicle to the nipple, and from the right margin of the sternum to the anterior fold of the axilla. The right side of the chest, measured over the tumour, exceeded the left in girth by three and a half inches; it was dull on percussion at all points anteriorly. The right pleura was full of straw-coloured serum and coagulated blood; the latter weighed three pounds. The right lung was compressed into the infero-posterior portion of the pleural cavity, was of a dark-slate colour, and emptied of air, with exception of the superior and middle lobes, which were expanded upon the posterior surface of the tumour, to which they were attached, and contained some air.

An enormous tumour, as large as the head of a newborn infant, occupied the anterior and superior portion of the pleural cavity, and was attached to the anterior wall of the chest, through which it protruded by eroding the second, third, and fourth ribs. It was unsupported at all other points, save by the adherent lung, and by its pedicle anterior and superior surface, through which it was connected with the anterior mediastinum. It was, as it were, suspended in the cavity of the pleura. On the posterior and inferior surface of this tumour, where it was uncovered by the lung, was a large and irregular rent, through which two fingers might be readily introduced, and from which protruded a jagged mass of partially decolorized blood-clot. The unattached surface of the tumour was invested by the parietal pleura.

The left lung was vascular on the surface and partially emphysematous on the anterior margin, but otherwise healthy.

The pericardium contained about two ounces of serum

* Dublin Quarterly Journal of Medical Science, Nov., 1854.

The heart presented a good deal of superficial fat at the base, and a thick layer in the front of the ascending portion of the arch of the aorta. On the right auricular appendix was a large "milk spot," and a similar one existed in the usual situation on the right ventricle; on the anterior surface of the left ventricle near the apex was a nodule of white adherent lymph, of the size of a small pea.

The right cavities were normal, the left ventricle much hypertrophied and diminished in capacity (see measurement below).

The valves were all in a healthy condition except the sigmoid of the aorta, which were slightly thickened, and permitted the slow return of water into the ventricle. The lining membrane of the aorta was rugous, and of a dirty, yellow colour, and in the right wall of the ascending portion of the arch, one inch to the cardiac side of the origin of the arteria innominata, was found a large and somewhat circular opening, admitting the points of three fingers, which led into a large aneurism (the tumour already described) partially filled with coagulated blood. The coagulum was adherent to the anterior wall of the sac, and protruded through the rent in its posterior wall; the inferior and internal portion of the sac was unoccupied by coagulum, and a probe introduced into the mouth of the aneurism readily passed through the rent into the cavity of the pleura.

The pulmonary artery and its valves exhibited no departure from the state of health; the three great vessels arising from the arch of the aorta were unaffected. Both pneumogastric nerves were much thickened.

The vena cava descendens and its tributaries, and also the right bronchus and the œsophagus, entirely escaped pressure. The heart was measured ninety-six hours after death, and yielded the following results:—

Dimensions of cavity of left ventricle.	}	Length of auricular portion—viz., from root of mitral valve to apex, 2 inches.
		Width—viz., from septum to posterior external wall, at central portion, $\frac{1}{2}$ inch; at base $\frac{3}{4}$ inch.
Thickness of walls of left ventricle.	}	Near apex $\frac{3}{4}$ inch.
		Near base $\frac{3}{4}$ inch.
		Middle portion 13-16th inch.

The preceding measurements are of some interest, as showing that the heart furnished an example of concentric hypertrophy without disease of the mitral orifice, and with partial disease, admitting of slow regurgitation, at the aortic orifice.

It would seem that the extra labour imposed upon the left ventricle of distending the large aneurismal sac, which must have been accomplished as a necessary preliminary to a complete and effective circulation, determined the increased development or hypertrophy of the walls of that cavity, and that the circulation was unusually effective, the character of the pulse, the fresh and ruddy complexion of the patient, and the total absence of anasarca, clearly proved. The occurrence of dilatation of the left ventricle, as a consequence of inadequacy of aortic valves, was prevented—first, by the very partial degree in which inadequacy existed, and secondly by the close proximity of a large aneurism communicating by an open mouth with the aorta a short distance above the valves. Into this large cavity, which thus served as a diverticulum, the blood must have rushed during the systole of the aorta, causing the second impulse of the tumour, and diminishing the pressure upon the sigmoid valves. The regurgitation into the ventricle and the diastolic pressure upon its internal surface was therefore much less than otherwise it would have been, and hence the absence of dilatation. Death was caused by the giving way of the sac on its posterior wall, where it was unsupported during the effort of the patient to sit up in bed, and at a time when its contents were being gradually solidified.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

DR. LYONS'S CLINIQUE.

TONSILLITIS. *Aphthous and Edematous Varieties; Caustic; Incision.*—This very common affection may be found worthy of brief commentary, and one of its forms is well illustrated by a case recently treated in Dr. Lyons's Clinique.

The patient, a young man, aged about 20, was admitted labouring under considerable dyspœna, extreme dysphagia, and with a marked amount of pyrexial excitement. He stated that he had not previously laboured under sore throat, and had been attacked a few days previously with rigors, pain in the neck, difficulty of swallowing, pain shooting up to the right ear, and all the usual symptoms which attend the invasion of tonsillitis.

On inspection there was visible swelling externally on left side, great distress in breathing and on attempts to swallow, and all the evidences of much febrile disturbance of the system.

On opening the mouth, which was accomplished not without difficulty, the left tonsil was found to be enormously engorged, projecting far beyond the mesian line, and carrying the uvula before it. It was also enlarged in a direction forwards, and had thrust the left anterior half arch of the palate, part of velum palati and contiguous tissues far forward into the mouth, causing very remarkable swelling of the parts involved, which were thrust forward so as to reach the level of the front molar teeth. The mucous membrane of the palate and inflamed parts was of a deep claret colour, and all the symptoms and appearances indicated the rapid advance of a high degree of erysipelatous inflammation. It might have been for some moments a question of grave debate as to what steps could be best taken for immediate relief of the urgent symptoms which were presented in this case; but relying on his former experience in circumstances very similar, Dr. Lyons at once proceeded by means of an ordinary gum-lanceet, or, as he prefers to call it, "*his favourite tonsillotome*," to make a few bold free incisions through the swollen organ by gently raking the instrument two or three times in a parallel direction from behind forwards, and to the depth of about one-sixteenth to one-eighth of an inch through the tissue of the gland. The result of this procedure is invariably to give exit to a considerable quantity of blood, and to allow the escape of the serum, the infiltration of which had caused the principal amount of the swelling which had produced so much distress, dyspœna, and dysphagia. After the free incision just mentioned, the patient was directed to freely gargle the throat with warm water. The result was, that in a brief period, partly from the escape of blood, and more particularly by the free exit of the serous fluid infiltrated into the tissues of the gland, marked subsidence of the swelling took place within a short period, and therewith relief was procured to all the principal sources of distress of which the patient complained. Convalescence was rapidly established in this case.

In commenting on the features of this particular case, Dr. Lyons took occasion to draw the attention of the class to the distinction which he believes to be so markedly observable between the two forms of tonsillitis which so very commonly come under the notice of the practising physician and surgeon—viz. :—

Aphthous Tonsillitis.—This term Dr. Lyons thinks may be applied very appropriately to one of the two common forms of tonsillitis. In this variety of the affection the tonsil is but little swollen; it is red, irritated, patchy in appearance, and here and there covered with buff-coloured spots or specks of yellowish or aphthous matter—a low form of exudative material. This affection is attended with smart sensation of pain and distress on swallowing, often with sharp fever

and marked evidence of a well-developed pyrexial state, including hot skin, quick pulse, thirst, foul tongue, and ultimately copious deposit of urates.

In this form of the affection Dr. Lyons's experience agrees with that of all observers, that the local application of solutions of the nitrate of silver, varying in strength according to the urgency of the case, acts as a sovereign and quite a specific remedy. He is satisfied, however, that the singular and almost magic efficacy of the local application in this particular form of the affection has been a source of grave error in another somewhat allied, but in the main wholly different, pathological condition of the tonsil. Dr. Lyons sums up his views by stating that *while Nitrate of Silver is the sovereign remedy for one—the aphthous variety of tonsillitis—it is not alone ineffective, but highly injurious, in that variety in which œdematous infiltration of the organ demands free incision by the gum-lancet as its natural and only efficient mode of relief.*

When the œdematous variety of tonsillitis is once established, the application of caustics in any form, solid or fluid, can, in Dr. Lyons's view, have only the effect of converting a simple œdematous infiltration into an inflammation in which lymph is exuded, and the tissues of the organ become for the time much more intensely inflamed, possibly enlarged, and certainly permanently condensed.

To the enlarged œdematous tonsil the application of caustic gives no relief, but perhaps the contrary, and this is especially seen when both tonsils are enlarged, project towards each other, and perhaps touch, and deglutition and in some cases ordinary respiration is performed with infinite difficulty. To apply caustic, under these circumstances, is but to aggravate the already excessive sufferings of the patient, while leeches, mustard poultices, and blisters are equally ineffective as means of relief to a condition which, to the patient, seems to threaten immediate suffocation, a result possible, though fortunately rare.

It is in circumstances like those here detailed that the practice of incision of the tonsils, according to Dr. Lyons's views, offers such advantages. Free exit is at once given to a certain amount of blood, free exit is allowed to the imprisoned serum; rapid subsidence of the swollen organs takes place, and deglutition and respiration are performed without difficulty, to the infinite relief of the patient, who has been momentarily fearing suffocation.

As to any possible danger from the operation of incision, it must be remembered, says Dr. Lyons, that, however closely approximate to those important vessels (internal and external carotid and maxillary artery) may be the tonsil in its normal condition as a much flattened organ, it is when enlarged separated from these vessels by the whole thickness of its own inflamed and infiltrated substance, often reaching the size of a large walnut. Dr. Lyons directs the operation to be performed by carefully raking the gum-lancet (the only suitable instrument for the purpose) from behind forwards; it incises the organ (now perhaps an inch in thickness) to the depth of one-eighth at most of an inch, and exit is given to blood and serum.

If performed sufficiently early, the occurrence of abscess in the tonsil may, in his opinion, be obviated in the great majority of cases, while another and equally important object is accomplished by saving the patient from that condition of chronically enlarged and hardened tonsil, so liable at subsequent periods to attacks of inflammation on the slightest occasion of cold, and which is too often the result of caustic misapplied.

In conclusion, Dr. Lyons observed that the case under consideration well illustrated the other marked features of this somewhat singular malady, in which, with a comparatively slight amount of local disease, marked general pyrexia was so commonly associated, as evidenced by heat of skin, accelerated pulse, nervous derangement, occasional sleeplessness and wandering, and in nearly all cases marked lysis of the diseased state by a free deposit of urates, accompanied by a marked odour of the sweat and breath, with an amount of debility consequent on the disease,

which nothing could explain short of a pyrexial act of the system of considerable intensity, and attended by tissue-metamorphosis and waste excretion of no small extent.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

CASES UNDER THE CARE OF MR. PORTER,

SENIOR SURGEON TO THE HOSPITAL.

[Reported by ARTHUR WYNNE FOOT, M.D.]

(Continued from page 395.)

STRANGULATED FEMORAL HERNIA; DIVISION OF THE STRICTURE WITHOUT OPENING THE SAC.

Case 8.—Kate Pibbs, aged 23, was admitted on the evening of the 5th of April with a femoral hernia on the right side, which had been in a state of strangulation thirteen hours. She had been fourteen months subject to a reducible hernia, and had worn a truss for about ten months. She had on one previous occasion suffered from symptoms of strangulation for several hours, but was relieved by the return of the hernia without surgical assistance. Upon her admission a very tense tumour, the size of a small walnut, presented in the right inguinal region, with constant vomiting and pain in the abdomen and back. The taxis had been tried for a short time before her admission, ineffectually and to the great increase of the pain and vomiting. Fresh attempts to reduce the tumour, gently made while she was in a warm bath, not having succeeded, she was put under the influence of chloroform, the skin pinched up and transfixed, the sac laid bare by careful incisions, and the stricture divided without opening the sac. The wound was closed by three wire sutures. Draughts containing twenty-five drops of Batley were given morning and evening on the following day.

A slight attack of local inflammation interfered with the early healing of the incision, and made it necessary to remove the sutures before it was closed. Matter formed, a poultice was applied, and the wound allowed to heal by granulations.

The advantages claimed by the advocates of division of the stricture without opening the sac have been illustrated in this case, which is the third in which this method, called Petit's operation, though not first employed by that surgeon, has been lately adopted in the Meath Hospital. The non-exposure of the intestine to the air by the division of the sac, and the consequently lesser risk of peritonitis or of hæmorrhage into the abdominal cavity, contribute to a more rapid recovery after this operation. A point particularly attended to by Mr. Porter with the view of securing a favourable result, was that the taxis should not be injudiciously persevered in after its careful employment had not been successful; the prognosis being so much influenced by the attempts at reduction, that Dessault always thought favourably of a case of strangulated hernia when the taxis had not been used.

STRICTURE OF THE URETHRA TREATED WITH HOLT'S DILATOR.

Case 9.—Edward Dolan, 36 years of age, was admitted with a tight stricture of the urethra about five inches from the orifice. No. 1 gum-elastic catheter could be passed with difficulty. The stricture had existed two years, and dated from the cessation of neglected gonorrhœa. He had frequently suffered from retention of urine; on one occasion, internal division of the stricture was performed with a cutting instrument in another hospital; but the disease returned. Mr. Porter introduced Holt's dilator, and forcibly divided the stricture. No pain was felt, and but a few drops of blood were mixed in the urine, which was drawn off by No. 8 silver catheter, introduced with ease immediately after the operation. Two grains of quinine and twenty drops of tincture of opium were given, and the man desired to keep his bed for the day. A few days

afterwards he was dismissed, No. 10 silver catheter passing through the urethra without any difficulty.

STRICTURE OF THE URETHRA TREATED WITH HOLT'S DILATOR.

Case 10.—John Carvin, 30 years of age, was admitted with a very tight stricture at the membranous portion of the urethra, which he stated he had suffered from for more than two years. The disease commenced to appear during the course of an attack of gonorrhœa. He had an instrument, No. 2 elastic catheter, passed, for the first time, after his admission. There was difficulty in getting it through the urethra. Holt's dilator having been introduced, the stricture was forcibly dilated. No. 10 silver catheter easily passed immediately afterwards.

PRIMARY SYPHILITIC ULCER, TREATMENT BY MERCURIAL VAPOUR BATH.

Case 11.—John Byrne, 30 years of age, was admitted on the 9th of April, with gonorrhœa, œdema of the penis, and phymosis, accompanied with a solitary chancre on the right side of the body of the penis, having an elevated, non-suppurating base, and surrounded with a margin of induration. He had contracted this ulcer five weeks before the period of his admission. It made its first appearance fourteen days after exposure to contagion, as a "watery blister." The œdema of the penis subsided soon under the influence of rest and position. With regard to the treatment of the chancre, Mr. Porter stated his intention of employing the method of mercurial fumigation, advocated specially by Mr. Henry Lee, for the purpose of healing the sore as quickly as possible, but clearly stated the certainty of secondary syphilis sooner or later following this infecting sore, which had been neglected until the period for abortive treatment had passed by. The solitary character of the sore, the late date of its appearance after contagion, the absence of suppuration from its surface, the surrounding hardness, the multiple induration of the lymphatic glands in the right groin, which, enlarging slowly, and without pain or tenderness, ness, indicated the infecting nature of the ulcer, and from the fact of the man not having applied for treatment until five weeks after the appearance of the ulcer and seven after the date of contagion, Mr. Porter concluded that the development of the secondary effects of the syphilitic poison was inevitable. The condition of the sore was rapidly improved by the mercurial vapour bath, and after its employment for a fortnight, the surrounding induration had been much lessened, and the base of the sore become disposed to cicatrise. Ten grains of calomel were sublimed with the vapour of water upon his body every evening. The bath occupied twenty minutes, and the course of fumigations caused no diarrhœa, salivation, or other unpleasant result.

Proceedings of Societies.

HARVEIAN SOCIETY OF LONDON.

APRIL 5, 1866.

Dr. BALLARD, V P., in the Chair.

Dr. BALLARD mentioned the case of a child in whose abdomen there could be felt masses about the size of pigeons' eggs in the umbilicus and lumbar regions. The bowels were regular, not relaxed; the child was in good health. The veins of the abdomen were enlarged. This led Dr. Ballard to the opinion that the child was suffering from malignant disease of the mesenteric glands, and Dr. West on being called in gave a similar opinion. It appeared that the paternal grandfather of the child had died five years ago of cancer of the liver, the father and mother were healthy.

Mr. SEDGWICK thought that a post-mortem examination would be necessary before the diagnosis of the case could

be clearly made out. If it were malignant, cachexia would not, he thought, be necessarily observed, as in cases of diseases of the eyeball in children cachexia was frequently absent.

Dr. COCK thought it unlikely that this case was one of cancer, since there was no pallor described, which he would expect if this case were one of carcinoma.

Dr. BALLARD promised to inform the Society of the progress of the case.

A debate was held "On the Treatment of Acute Articular Rheumatism."

Dr. CHARLES DRYSDALE said that the treatment of this disease was first seen to be of great importance when M. Bouillaud, in 1832, pointed out the frequent occurrence of heart disease with acute articular rheumatism. A violent dispute had ensued between that gentleman and M. Chomel. The latter physician thought that rheumatic fever should not be considered an inflammatory disease, that it occurred chiefly in those predisposed to it, and he contended that bloodletting therefore prolonged the duration of the disease, and produced sounds resembling those of valvular disease. The duration of the fever was, when let alone, from seven to nine days. Bouillaud, on the contrary, considered that cold was the sole cause of rheumatism, and maintained that the coincidence of heart disease was the rule, not the exception, in this disease. He therefore advised antiphlogistics, and especially the loss of large quantities of blood, which he said cut short the fever and prevented the heart complication; in short, acute rheumatism was, like pleurisy, &c., one of the types of inflammatory disease. The average amount of blood taken by him in cases of acute rheumatism was about four and a half pounds in the course of the disease. The mean time of the duration of the disease was nineteen days. Of seventy-four cases of rheumatism of great intensity, mentioned by Bouillaud, heart complications were noticed by him in sixty-four. Passing on to other treatment, nitre in large doses, $\mathfrak{z}i.$ to $\mathfrak{z}i\bar{i}$, in twenty-four hours, had been praised by Dr. Basham; lemon juice also had been praised by Dr. O. Rees. Dr. Williams' plan of treatment was to commence with a purge, and then administer vinum colchici in an alkaline mixture, with cupping and leeches, and calomel and opium in cases of cardiac complication. The treatment by means of large doses of bicarbonate of potash was probably introduced by Dr. Golding Bird, and had been very warmly advocated by Dr. Garrod and Dr. H. Fuller, who had supported their assertions by large statistical inquiries. Dr. Fuller had said that he had never seen a case of heart disease follow when this treatment was used, except in two or three cases, where it had supervened within twenty-four hours of the commencement of the treatment. Dr. Gull, on the contrary, asserted that he had found this plan of treatment a failure, as he had also the use of colchicum, Dover's powders, &c. Dr. Gull said that he had been most successful by keeping the patient quite quiet in bed and on simple diet. One of the most recent writers on this subject, Dr. K. Chambers, had, in addition to the use of alkalis in large doses, laid very great stress upon the necessity of enveloping patients in blankets, in order to prevent the heart's excessive action when variations of temperature took place. He stated that this bedding in blankets reduced from sixteen to four the risk of inflammation of the heart. Dr. Chambers objected to the use of mercury in pericarditis. The alkaline treatment, Dr. Drysdale said, rested on the assumption that the fluids of the system were unduly acid in rheumatic fever. Now, the urine was scanty and of high specific gravity, and certainly reddened litmus paper greatly. But all this was owing to the concentration of the fluid, and the free acidity of the urine was in reality reduced; the sweat, too, was by no means invariably acid, and the blood was alkaline, so that the alkaline treatment could not be said to have much a *priori* argument in its favour. But any remedy which had no such *a priori* argument was merely an empirical one, and had an infinity of chances against being

what it was asserted to be—namely, a specific against the occurrence of cardiac affections in acute rheumatism. Nothing short of this was claimed for it by Dr. Fuller, who thought that no discovery in medicine since the days of Jenner had been of such consequence to the race as that of the use of large doses of the alkalies in this disease. He (Dr. Drysdale) had the greatest respect for any assertion made by such eminent observers as Dr. Fuller or Dr. Garrod; but he would simply say that the probabilities were so great against the affirmative side of the question as to make scepticism quite imperative, until more extended comparisons had been made between the treatment by alkalies and the ordinary plan, as pursued in Paris, and by Dr. Gull and others—*i.e.*, attention to the perfect tranquillity and warmth of the patient. As to blood-letting, this practice had reposed for its theory on the idea of getting rid of the superabundant fibrine from the blood, and was now justly abandoned, and he must say that he had himself seen fresh joints implicated and the heart affected when Oij . of bicarbonate of potash was given every two hours. As to calomel and opium in pericarditis or other inflammations, he would repeat what he had said before, that Drs. Walshe, Hughes Bennett, and many others of the best modern physicians, considered that it was never of the slightest service in such complaints—an opinion in which he completely concurred. Dr. Herbert Davies' plan of extensive vesication appeared to have one undoubted merit in some cases—*i.e.*, it greatly alleviated the pain of the acute rheumatism. Blisters two inches in breadth were made to encircle the joints, and as much as three or four hundred square inches were placed on some patients. With respect to the other claim brought forward by the author of this plan of treatment—*i.e.*, that it produced immunity from heart complications—it would require many more facts than those adduced to prove this. He (Dr. Drysdale) was disposed to believe that in acute rheumatism in very young persons no treatment would, in some cases, prevent the occurrence of pericarditis or endocarditis. Summing up, as well as he could, the foregoing evidence, it appeared to him that the best treatment for acute articular rheumatism consisted in perfect tranquillity, warmth, and careful nursing, together with the employment of Dr. Davies' plan of extensive vesication, whenever this was found to alleviate the agony of the joints. He felt, concerning alkalies, almost convinced from evidence, and from his own experience, having very frequently employed them, that this plan was no specific prophylactic of heart disease. As it was, however, a most important remedy, if really all that was said about it could be proved, he hoped that Dr. Fuller and other gentlemen would again announce the results of their recent experience on this important matter.

Dr. COCK said there was one point in which he agreed thoroughly with Dr. Drysdale—namely, that mercury did no good in acute rheumatism, rather a great deal of harm. Dr. John Taylor had clearly proved, at University College Hospital, that it had no effect in preventing or in curing pericarditis. When assistant to Dr. Garrod, he had seen the experiments of that gentleman with bicarbonate of potash. A scruple or two of the salt was administered every two hours, notwithstanding which, some of the patients thus treated had rheumatic pericarditis. In some cases of rheumatic pericarditis the heart disease is the sole affection, and no external rheumatism exists. Dr. Herbert Baker had lately come to the conclusion that the treatment that was as successful as any in cases of acute rheumatism was rest and warmth. No peculiar drug could be depended on. He had found carbonates and citrates of the alkalies useful in some cases. Colchicum occasionally did good. No specifics did good in this disease, and we must get the emunctory organs to do their work; thus mercury and chalk, with Dover's powder, were useful as purges and sudorifics. Linseed-meal poultices were a good application to the joints.

Dr. BALLARD said that we were probably wrong in con-

sidering one remedy as always likely to do good in acute rheumatism. He had of late always used blisters, according to Dr. Davies' plan, in all cases of acute rheumatism which he had been called to, and was accustomed to carry a small phial of blistering fluid constantly about with him for the purpose. If a joint were well blistered the pain would leave it. Salines were useful in rheumatism, and alkalies and opium were also very serviceable; a combination of remedies was perhaps the best. In a case of acute rheumatism he had lately treated he brushed every joint over with the blistering fluid, and over the heart also, and in eight days the patient was well, and had had no recurrence of the pain. He doubted whether the effect of alkalies alone was sufficient to allay the disease.

Mr. CURGENVEN said that patients had a notion that all diseases had a remedy, and this belief affected medical men a little. In his experience of disease he had found but one specific for any disease—*viz.*, quinine in ague. He thought hospital experiments were valuable, in so far as they gave an idea of what the natural history of the disease was. He had found the saline and alkaline plan of treatment the best of all. He had in his own person experienced an attack of acute rheumatism before the alkaline treatment had come into fashion, and had been treated for six weeks by diaphoretic mixtures. He found much relief from nitrate of potash. A gentleman, since a great authority, had recommended bleeding $\text{ad. } \text{ʒxxiv}$. and salivation, but he demurred to this. Since he had adopted the alkaline treatment he had not seen any case last longer than a fortnight. But it was a curious fact that some years acute rheumatism seemed to be far more dangerous than others, for sometimes no case of heart disease would occur, whilst at other times almost every case would exhibit symptoms of pericarditis. Beer was very bad for rheumatic persons.

Dr. MEREDYTH said that rheumatism was much more common in London than in Paris. There was little rheumatic fever in the Crimea. With regard to treatment, the plan of M. Bouillaud and the expectant plan had been found to yield the same result. Tr. of colchicum and opium he had found beneficial in some cases, with occasionally a teaspoonful of calcined magnesia.

Mr. PARKER YOUNG said that Dr. Chambers, besides laying great stress on the bedding of his patients, had given half-drachm doses of bicarbonate of potash every two hours. The patients certainly got rapidly well under this treatment. We ought to look at acute rheumatism as we did other fevers. There was no specific for any fever. We cannot cut short scarlatina or small-pox. In rheumatic fever the patient should be fed frequently with milk, given every two hours. From three weeks up to six weeks was the usual time of its duration.

Dr. WESTMACOTT recommended cotton with oiled silk as an application to the joints.

Mr. SEDGWICK said that rest was of great importance, even when it was possible for the patient to move about. He had relied almost exclusively on bicarbonate of potash of late, and in young persons he had added nitrate of potash, since this salt was supposed to have the power of keeping the blood more soluble. The frequency of heart disease was inversely as the age. In young children pericarditis was almost always an accompaniment of acute rheumatism. He had heard of a congenital case of acute rheumatism. Lemon juice was in many cases quite as successful as bicarbonate of potash. Blistering was, he thought, theoretically likely to do good. Topical applications were now coming much into use.

Mr. OWEN said that the enemy in rheumatism was the acid, and the question was how we could but get quit of it from the system. He had seen a gentleman who had been bled for fifteen days without benefit. Blisters, by the serum they collected, did good in cleansing the blood. The alkaline treatment alone was not sufficient. Whatever remedy was used, he thought the effect desired to be produced was the elimination of the acid. Lemon juice did this also, probably by some chemical process.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, APRIL 4, 1866.

Dr. BARNES, President.

THE following gentlemen were elected Fellows:—Drs. J. Carless, Astley Cooper, Hornblow, Sheraton, T. J. Walker, A. Wiltshire, John Wilkins; Messrs. A. J. Lowe, R. Roberts.

Dr. GERVIS exhibited a specimen of a Fœtus possessing many points of interest in its physiological development.

Dr. MEADOWS exhibited a specimen of Cystic Development of the Fallopian Tubes consequent on obstruction at the ostium uterinum. The left tube contained two cysts; the right, one. They were each about the size of a small walnut, and filled with a thick brownish fluid. The patient had died of pelvic peritonitis, the result of menstrual suppression from cold.

Dr. MEADOWS also showed a new Intra-uterine Stem. It consisted simply of a solid glass rod, the size of No. 6 catheter, two inches long, and having a flat disc at the vaginal end. He had been led to adopt this form from the inconvenience sometimes arising from the irritation of the ordinary metal or ebonite stems, glass being not only cleaner and free from corrosion, but for these reasons more easily borne than either of the others.

Mr. MARSHALL of Dover, related a case of

DISEASE OF THE PLACENTA;

with notes by Dr. GRAILY HEWITT, who considered that the condition of the placenta was not one of fatty degeneration, but likely to be the result of effusion of lymph at a period probably two or three months antecedent to delivery. The yellow layer described had the appearance of syphilitic disease; but there was no history of that disease having affected the patient. The drawing before the Fellows well illustrated the chief features of the specimen.

The PRESIDENT considered the case not so very uncommon. The physiological explanation consisted in the fact of there being an excess of fibrin in the blood of pregnant women. He believed the case to be neither one of fatty nor of fibrous degeneration, but one in which fibrin had been thrown out. The yellow layer and whole appearance of the placenta did not, in his opinion, necessarily indicate the existence of syphilis in the system.

Dr. GREENHALGH gave the history of a case of

OBSTRUCTIVE DYSMENORRŒA.

He considered dysmenorrhœa to be either congenital or induced; and the stricture to be of two kinds, absolute or relative. After referring to the various modes of treatment, the author stated that, in the case under consideration, he had had extreme difficulty in passing a sound. He was obliged to draw the uterus down by Sims's needle, and then made use of his (Dr. Greenhalgh's) metrotome. In the course of four days after the operation the patient complained of an ill-defined pain all over her. She gradually got worse, vomiting came on, and she died on the ninth day after the operation. At the post-mortem peritonitis of a low form, with considerable tubercular deposit, was found; the uterus was bound down by old adhesions, and the incision had not gone right through the os internum. Her death was considered to be due to her want of care after the operation. The author concluded by referring to all the cases he had operated on, which had usually done well, and stated his strong objection to the introduction of sponge-tents after operating.

Dr. BARNES considered that the danger rested in cutting the os internum. He thought very little danger was to be feared from incision of the os externum. The cervix uteri might be treated by dilatation. He agreed with Dr. Greenhalgh that absolute rest was necessary after operation, and believed that the case would be a lesson to all,

and make them adopt every precaution, or even hesitate to incise the internal os.

Dr. ROUTH expressed his thanks to Dr. Greenhalgh for bringing the case before the Society. He thought the operation was one of danger, and required the greatest possible care both before and after. The case was a very unfortunate one, from the length of time occupied in operating, as also from there being no loss of blood; he always liked to see three or four ounces lost. He did not think there was any danger from cutting the internal os when the fundus uteri was free from inflammation. Fatal cases were known after passing the ordinary sound.

Dr. ROGERS agreed with all that Dr. Routh had said. He considered the internal os to be frequently the seat of stricture. He added his testimony to the danger that sometimes attended incision of the cervix, and stated that he had also lost a case after operation.

Dr. RASCH said that he had never met with a case where there was stricture of the internal os, nor had he ever failed to pass a sound. Cases said to be strictured he had found flexed, which on being reduced admitted the sound.

Dr. MEADOWS remarked upon the necessity of ascertaining, as far as possible, the condition not only of the uterus, but of its appendages also, in all cases where operative measures were contemplated. He believed that in those cases where a fatal result had followed even so simple a proceeding as the passage of the uterine sound, some organic lesion would be found to have been the cause of the mischief, the uterus being exceedingly sensitive of any interference under these circumstances. Unfortunately the diagnosis of some of these conditions was often very difficult, and the real state of the case was only discoverable on a post-mortem examination. In Dr. Greenhalgh's case there was reason to suppose that some displacement of the uterus existed, and the history was one indicative of previous metro-peritonitis. This being so, and the fundus uteri having become adherent in its malposition, he would regard such a case as positively contra-indicating any operative interference. He believed that in all cases of flexion of the uterus, especially when of long standing, or of version when replacement was a matter of difficulty, the use of the knife was very likely to lead to evil and even fatal results.

Dr. Gervis, Dr. Head, Dr. Ball, Dr. Eastlake, and Mr. Baker Brown, jun., also took part in the discussion.

Dr. GREENHALGH having replied to the various speakers, the meeting adjourned.

SURGICAL SOCIETY OF IRELAND.—APRIL 20.

Dr. WILMOT, President of the College, in the Chair.

MR. CROLY read the following paper on
SCALDS OF THE GLOTTIS AND THEIR TREATMENT BY
MERCURY.

There are no cases met by the surgeon more painful to witness or requiring more careful treatment and anxious watching than those designated "scalds of the glottis." The subject has been alluded to by most surgical and medical writers, by some (as I shall refer to by and bye) in special and able articles, by others in a less striking way. The importance of the subject I consider a sufficient apology for bringing under the notice of the Society the following cases which came under my observation lately in the Children's Ward of the City of Dublin Hospital:—

John Mooney, aged 2 years, was admitted into the City of Dublin Hospital on Monday evening, December 11th, 1865, at 4-15 o'clock. His mother, who carried him to hospital, stated that at twelve o'clock on that day the child attempted to drink water from the spout of a kettle which was boiling on the fire at her residence (9, Stephen's-place); he spat out the water at once, and suffered much pain from the scalded state of his mouth and lips, which were rapidly blistered; he cried constantly, put his hands up to his

mouth and called out for drinks. At four o'clock his breathing became affected, and his mother lost no more time in seeking relief for him; I was sent for at once and arrived shortly, when I found the child in the following condition, which I noted:—Face very pale, extremities cold, mouth open, tongue protruded, lips vesicated, pulse rapid and feeble, urgent dyspnoea, croupy and stridulous breathing. I endeavoured to feel the epiglottis with my finger, but the child resisted, and so severe a spasm was produced that I did not attempt any further examination of that kind; no dulness on percussing the chest, but rales were heard. The mother told me the child had just recovered from a severe attack of bronchitis. I had the child's bed brought near the fire; a hot jar applied to the feet; warm flannels wrapped round the body, and a little warm wine and water administered, which the child swallowed with considerable difficulty; it made an occasional violent effort to drink, but could not always succeed. I placed a screen round the bed and closed the windows and door, so as to keep up a warm temperature.

I next rubbed in freely the strong mercurial ointment to the axilla, chest, abdomen, and inside of thighs; applied hot flannels over the chest, and prescribed calomel and James's powder, one grain of each to be given every hour.

The symptoms became aggravated at times; the child was drowsy and tossed about in a restless manner. The instruments required for tracheotomy were arranged on the tray by Mr. Irving, the senior resident pupil, when I was sent for.

I remained in the ward watching the case and considering what ought to be done.

I recollected my friend Dr. Bevan having mentioned to me, some years ago, that almost all the cases of this kind in which he had performed tracheotomy died, and those treated by the mercurial plan recovered. My colleague, Dr. Hargrave, saw the case with me soon after admission to hospital.

At 9:30 Dr. Hargrave again visited the child; the symptoms still continued severe. At 10:30 (five and a half hours after the child's admission) I left the hospital, with directions to keep up the mercurial treatment and *stimulants*, and to send for me if the child got worse.

Twelve o'clock: Mr. Irving noted—Child in heavy stupor.

Half-past two o'clock: Bowels affected (green-coloured evacuation); child coughs occasionally.

Three o'clock: Breathing in every respect better; respiration 52 in minute.

Seven o'clock: Perspiring copiously.

Half-past eight o'clock: I saw the child; breathing much less distressed; child asked for a drink.

Half-past nine o'clock: Breathing freely; took plenty of wine and beef-tea all day; bowels acted well; *free discharge of saliva*.

13th: Well.

The second case occurred in a child, 3 years of age (a year ago); the symptoms were not so urgent as in the last one; it was treated by mercury; child became profusely *salivated*, and remained some time in hospital with sore mouth. I regret that the notes taken by Mr. Wheeler have been lost.

I shall next read a brief extract from various authors, and then a tabular statement of cases treated by mercury and those in which tracheotomy was performed, for the purpose of comparison.

Mr. Samuel Cooper, in his "First Lines," page 738, says:—"In University College Hospital tracheotomy has been performed in several instances of this kind, but generally without success."

Mr. Cooper also says (in a note):—"One or two children under me recovered under the free use of calomel."

The late Professor Porter, in his excellent practical work on the "Larynx and Trachea," says (at page 177):—"Some of the most beautifully successful operations of bronchotomy that have ever been performed were undertaken for the relief of the accidents that form the subject

of this chapter; at the same time that I believe *there is no case in which it has been so often found to fail.*"

And at page 186 the same distinguished surgeon says:—"In the management of these cases, then, it is evident that a vast deal must be left to the discernment of the surgeon in the first instance, and to his decision afterwards. Where we have such abundant evidence of the occasional success of *antiphlogistic* measures, I think they should always be adopted and persevered in until the breathing becomes so affected that there is every *reasonable probability* of the operation becoming necessary. At this crisis it should not only be proposed, but its advantages impressed upon the patient's friends; and although a person might thus be now and again subjected to it without absolute necessity, yet I feel convinced that numbers would be preserved that otherwise are doomed to perish.

"Even in extreme cases, although not friendly to the performance of operations, unless on pathological principles, I do not think it ought to be absolutely declined; it affords only a chance; but it is a chance that should be offered, because in the present state of our knowledge there is much uncertainty, and the records of surgery give encouraging assurances of its *occasional* success."

A successful case of tracheotomy, performed by Mr. Adams under most unpromising circumstances, is then detailed. Bronchitis followed.

Professor Hargrave, in his practical work on "Operative Surgery," page 327, under the head of Laryngotomy and Tracheotomy, says:—"When boiling water has been swallowed, which causes such inflammation of the mucous membrane about the rima glottidis, and effusion into the lax submucous cellular tissue, situated in this place, as will prevent any air being admitted into the lungs; by the operation the free ingress and egress of the air is preserved and suffocation prevented, until all the inflammatory symptoms have subsided, when it will then resume its natural course."

TRACHEOTOMY FOR SCALDS OF THE GLOTTIS.

Extract from the London and Provincial Practice of Medicine and Surgery, October, 1859.

All the cases in this group have, of course, young children for their subjects. It would appear that the age liable to the accident of scalded glottis is between twelve months and five years. Children *under* the age of a year are unable to accomplish the feat of drinking from the kettle-spout, and those upwards of five are too sensible to attempt it. It might have been supposed that this extraordinary form of accident would occur with extreme rarity; but, as will be seen, we are able to adduce *fourteen* examples of it. Of these fourteen cases *eleven* ended in death, and *only three* in recovery. In one the fluid was heated oil, but in all the others it was boiling water from the kettle. Nearly all the little patients were between two and three years old, three or four only being above or below these limits of age.

Extract from Liston's "Elements of Surgery," page 440.

He says:—"The fauces and larynx of children are occasionally injured by the attempt to swallow by mistake boiling water, and *inhaling the steam*. The alarming symptoms follow in a very few hours, in consequence of the formation of numerous minute vesicles, with swelling, from effusion of serum into the submucous tissue. Great pain is generally experienced at the moment, but after crying violently the child may fall asleep and awaken croupy, and with threatened suffocation. By this time inflammatory action has been fairly established, the *submucous effusion* has begun to take place, and it is this that gives rise to the danger.

"The *excited* action is to be combated by *leeching* and *exhibition of calomel* in small doses, with or without opium frequently repeated, so as to arrest the lymphatic effusion, which is apt to supervene. When these means fail, tracheotomy must be resorted to without delay.

"The fauces and upper part of the larynx are only in-

volved at first; this practice is sound and good, success may be expected from the operation."

Miller, in his "System of Surgery" (page 865), says:—"If antiphlogistics fail and asphyxia threaten by obstruction in the larynx, tracheotomy is to be had recourse to at once; not reserving the operation, especially in the child, until by the extreme urgency of the symptoms it cannot possibly be longer delayed, and recovery is rendered more than problematical by congestion in the brain, in the lungs, or in both."

In the 3rd vol. of the "Dublin Hospital Reports," page 379, two cases are recorded by Dr. Burgess of Clonmel, in which bronchotomy was performed; one recovered and one died. He says he met five cases—two were treated by tracheotomy—and that he published them with a view of encouraging early bronchotomy.

"Holmes' System of Surgery," vol. 3, recommends in early stages of laryngitis vigorous antiphlogistic treatment. Mercury rapidly; tartar emetic, if used, should be given in such doses as to diminish the circulation, but not to cause vomiting, since the contents of the stomach might enter the larynx and produce suffocation.

"The time," he says, "for bleeding has passed when respiration becomes greatly obstructed, and this may be known by the leaden hue of the features, blueness of the lips, a cold clammy skin, and feeble pulse. Bleeding under such circumstances would be worse than injurious. It would probably be fatal.

"If the surgeon finds that the antiphlogistic treatment fails, or if he has been summoned to the case in its more advanced stage, he should at once propose tracheotomy."

Mr. Erichsen says:—"If urgent symptoms of dyspnoea set in, tracheotomy must be performed without delay."

Erichsen also says:—"In the majority of cases that have fallen under my observation, in which the operation has been performed, the issue has been a fatal one from the speedy supervention of broncho-pneumonia."

Druitt (author of the "Surgeons' Vade-Mecum") says:—"Scalds of the glottis, through swallowing boiling water or corrosive fluids, produce the ordinary symptoms of laryngitis, suffocative cough, and dyspnoea. Treatment.—Leeches, ice to the throat, opiates or chloroform to tranquillize, and tracheotomy if required."

In the *Dublin Quarterly Journal* for February, 1848, Dr. Jameson, one of the Surgeons to Mercer's Hospital, published an admirable paper on "Œdema of the Glottis," occasioned by attempting to swallow boiling water, illustrated by thirteen cases.

In eleven of those cases tracheotomy was performed, and eight died.

Two cases, treated by leeching and calomel, recovered; one of them was brought out of hospital too soon by the friends, got bronchitis, and died.

Dr. Jameson says: "In all cases, when boiling water has been taken, or attempted to have been taken, into the mouth, the danger at all times is imminent; for, although the little patients seem to suffer comparatively very little for the first few hours, still symptoms of grave importance set in sooner or later, which, if not combated by appropriate treatment, will either kill the patient or call for the operation of tracheotomy. The operation is, therefore, I think, imperatively called for, when the usual remedies, such as emetics, leeches, and the application of heat to the surface, &c., fail in allaying the urgent symptoms."

In the same journal for February, 1860, Dr. Philip Bevan (also Surgeon to Mercer's Hospital and Professor of Anatomy in the School of this College) published a paper on "Scalds of the Larynx," and gives the notes of four cases, all urgent, treated by leeching, antimony, and mercury, without operation; all recovered.

Dr. Bevan divided the symptoms into three stages. In the first the mouth and fauces alone are affected, but the respiration is unimpaired. In the second the ingress of air is impeded by laryngitis; and œdema glottidis and incipient congestion of the lungs are the result.

In the third stage engorgement of the lungs and consequent congestion of the brain are added to the previous symptoms.

The cases, says Dr. Bevan, I now publish were fully as bad as to justify the operation; the stridulous breathing, bloated pale features, fixed pupils, rapid feeble pulse, congested lungs, cold surface, hard erect epiglottis, and incipient coma, were certainly as bad as in many cases where I have both operated myself and seen the operation performed by other surgeons without success. I therefore have a right to conclude that had the operation been performed not more than one out of the four would have recovered.

If a patient, he continues, is in *extremis*, then, no doubt the surgeon is justified in trying the operation, as, although nearly hopeless, it is the only treatment which can save the patient from immediate dissolution. Still I believe that the antiphlogistic treatment, if conducted with sufficient rapidity, will be far more successful. Dr. Bevan commences his treatment with an emetic, followed by a cathartic enema, then leeches to the sternum.

In the second stage he gives calomel every hour or half hour, and repetition of leeching, and the body to be rubbed with mercurial ointment.

As soon as the mercury produced the green stools the symptoms in every case were improved, and the child recovered. Lungs first relieved, the brain next, and the larynx last of all.

Dr. Bevan never saw an instance of death when mercury had affected the system except when tracheotomy had been performed. He says he hopes others may be induced to publish their cases treated by mercury.

Through the kindness of my friends, Mr. Porter and Dr. Hughes, I am enabled to exhibit two beautiful drawings. The first, taken from a child who died in the Meath Hospital under the care of the late Professor Porter—cause of death being bronchitis brought on by swallowing boiling water. Vesications on the root of the tongue (alluded to by Liston) are well seen, also the vascular state of the lining membrane of the larynx and trachea. The other drawing (a very beautiful one) shows the hepatized condition of the lungs and the vascular state of the lining membrane of the trachea.

It is quite evident from what I have just read that every writer on this important subject recommends leeching and calomel treatment, but all speak of tracheotomy as the special chance of saving life. It appears to me that Dr. Bevan was the first surgeon who gave up the operation, and relied solely on the mercurial treatment. I feel certain that either of my cases was sufficiently severe to warrant tracheotomy, and I am equally sure that at all events the child Mooney, from his exhausted condition and delicate chest, would have died, had I operated, either at the time or subsequently, from bronchitis or pneumonia. In one of my cases salivation occurred. I am of opinion that dry cupping the chest, especially over the base of the lungs, would relieve the congested condition of those organs, and I would suggest turpentine fomentations to the chest afterwards, due precaution being taken not to expose the child unnecessarily. Keeping up the temperature of the room is of great moment, and the exhibition of stimulants and light broths to support the exhausted condition of the little sufferers.

The practitioner should have his mind made up how he is to treat such cases of emergency. If he looks to any of the modern class books he finds no special line of treatment recommended; all lean to operation, and thus life after life is lost. The mercurial treatment is not sufficiently known, and though it may appear to allow the symptoms to go on unchecked its action as an accumulative medicine is in no case, perhaps more, sudden or effective than in those now brought forward. I am in hopes that by following the footsteps of my friend, Dr. Bevan, in publishing my two cases treated by mercury, others may be induced to do likewise, and thus be the means of saving the lives of the little sufferers who unfortunately attempt to drink boiling water from the kettle-spout.

**TABULAR STATEMENT OF FOURTEEN CASES OF TRACHEOTOMY
FOR SCALDS OF THE GLOTTIS.
ELEVEN DEATHS.**

NO.	HOSPITAL AND SURGEON.	AGE.	TIME ELAPSED BETWEEN ACCIDENT AND OPERATION.	SYMPTOMS.	OPERATION.	RESULT.	REMARKS.
1	Guy's — Mr. Birkett.	3½	7 hours.	Distressing dyspnoea.	Tracheotomy.	Progressed favourably for a week, and then died rather suddenly.	Post-mortem examination revealed acute pneumonia.
2	Guy's — Mr. Callaway.	3	18 hours.	Almost dead from dyspnoea.	Tracheotomy—Probably hæmorrhage (into trachea?).	Never rallied, died nine days after the operation.	
3	Guy's — Mr. Callaway.	1	3 or 4 hours.	Symptoms of laryngitis suddenly supervened.	Tracheotomy—Great relief.	Recovered.	Canula removed in six days.
4	Guy's — Mr. Callaway.	3	7 hours.	Urgent dyspnoea.	Tracheotomy—Immediate relief.	Recovered well.	
5	Guy's — Mr. Birkett.	2½	7 hours.	Suffocation impending.	Tracheotomy.	Recovered.	The child had suffered from whooping-cough, which returned severely after the operation.
6	The London — House Surgeon.	1½		Intense dyspnoea	Tracheotomy—Great relief.	Died in twenty-four hours.	Autopsy—Epiglottis charred and shrivelled and great œdema of glottis.
7	The London — Mr. Wordsworth.	4	5 hours.	Dyspnoea.	Tracheotomy—Great relief.	Dyspnoea returned; death took place in fifty hours.	Autopsy—Charring of the glottis and epiglottis, and collapse of parts of the lung.
8	The London — Mr. Wordsworth.	2½	1½ hours.	Dyspnoea.	Tracheotomy.	She did well for twenty-four hours, when symptoms of bronchitis set in and proved fatal in eighteen hours.	Autopsy—The larynx only examined. Mucous membrane inflamed and swollen—so as to obstruct the rima glottidis.
9	St. Georges'.	5			Tracheotomy.	Died in a few hours.	
10	St. Bartholomew's.	3		Dyspnoea.	Tracheotomy—Great relief for some hours.	Symptoms of acute bronchitis set in sixteen hours after operation, and death followed in eight hours.	Autopsy — Extensive injury about the glottis and pneumonia.
11	Staffordshire General Infirmary—House Surgeon.	2		Suffocation imminent.	Tracheotomy—Great relief for two days.	Death on fourth day.	Autopsy — Acute softening in right lung and about its root.
12	The Middlesex—House Surgeon.	2		Dyspnoea.	Tracheotomy—With relief.	Death from exhaustion in thirty hours.	
13	St. Mary's—Mr. Spenser.	3	17 hours.	Urgent dyspnoea.	Tracheotomy—Immediate relief.	Death in thirty-six hours.	Autopsy—Epiglottis thickened, and with neighbouring mucous membrane, coated with lymph; lungs congested.
14	King's College—House Surgeon.	3½	12 hours.	Unable to speak or swallow.	Tracheotomy.	Died—The respiration was almost natural from removal of canula (5th day) until death which appeared to be from exhaustion.	

**TABULAR STATEMENT OF SIX CASES OF SCALDS OF THE GLOTTIS,
TREATED BY MERCURY.—WITHOUT OPERATION.
ALL RECOVERED.**

NO.	HOSPITAL AND SURGEON.	AGE.	{TIME ELAPSED BETWEEN ACCIDENT AND COMMENCEMENT OF TREATMENT.	SYMPTOMS.	TREATMENT.	RESULT.
1	"Mercer's"—Dr. Bevan.	2½	15 hours.	Respiration most difficult, hurried, and stridulous.	Tartar emetic, leeches, calomel.	Recovery.
2	"Mercer's"—Dr. Bevan.	3	15 hours.	Difficult and croupy respiration; epiglottis swollen; sonorous râles over base of both lungs.	Tartar emetic, leeches, mercurial ointment.	Recovery.
3	"Mercer's"—Dr. Bevan.	1 10m.	3 hours.	Stridulous and croupy breathing; cold extremities; cold sweat over face and chest.	Leeches, antimony, mercurial ointment.	Recovery.
4	"Mercer's"—Dr. Bevan.	2½	8 hours.	Stridulous breathing; cold clammy sweat over body.	Tartar emetic, calomel, mercurial ointment.	Recovery.
5	"City of Dublin"—Mr. Croly.	2	5 hours.	Urgent dyspnoea; cold clammy sweat; croupy breathing; cold extremities.	Mercurial ointment, calomel with James's powder, stimulants, hot applications to body.	Recovery.
6	"City of Dublin"—Mr. Croly.	3		Stridulous breathing; scalded lips; congestion of face.	Mercurial ointment, leeches, calomel, and James's powder.	Recovery.

I venture to offer the following aphorisms, the result of my inquiries, on "scalds of the glottis."

1. The water is not swallowed, but the steam produces œdema of the glottis.

2. The affection divided into three stages (Dr. Bevan).

3. Symptoms not urgent at first, apt to mislead those not experienced in such cases.

4. Importance of active *mercurial treatment* (not *antiphlogistic*), from the moment we first see the child, by applying strong mercurial ointment to the axillæ, chest, and inside of the thighs, and administering calomel in grain or two-grain doses every half hour or hour.

5. The necessity of having the apartment kept warm (a thermometer being used for guidance) to prevent chest complications.

6. Depletion by leeches or antimony must (if adopted) be used *early* and with *caution*.

7. The collapse should be treated by stimulants if the child can swallow, if not, stimulating and nutritive injections should be administered, the extremities being kept warm.

8. The lungs are almost invariably congested at some period of the illness, bronchitis or pneumonia being a common cause of death.

9. I suggest dry-cupping over the back of the lungs, followed by turpentine fomentations, to relieve pulmonary congestion.

10. When the green stools appear early (or salivation occurs) the child gets *suddenly* well. *This is very remarkable, and occurs most unexpectedly.*

11. Tracheotomy ought not in *my opinion* be performed in these cases.

Dr. GEOGHEGAN begged to say, in confirmation of what had fallen from Mr. Croly with respect to Dr. Bevan's treatment, that he adopted that treatment in one case with eminent success. There was no salivation whatever produced by the mercury; but as soon as the bowels became affected, and the green stools began to be passed, the symptoms became mitigated, there was a general

amendment, and, finally, complete recovery. He had not had large experience as regards operations in these cases, but so far as he had operated the result had been unfortunate. He had tried the mercurial treatment in one case only, and the results were so satisfactory that he would feel encouraged to persevere in that treatment. It was remarked by Mr. Croly that this mode of treatment was not much known, and that observation was supported by the fact, that a paper recently appeared in an English medical journal from the pen of one of the most eminent physicians, showing that he had not read Dr. Bevan's paper very carefully, for he attributed the cures to antimony and not to mercury. It was interesting to consider the mode in which mercury acted in these cases. It must be some species of revulsion by which pulmonary congestion and congestion of the bronchial passages, small and great, were thus reduced. They were entitled to assume from the results of Dr. Bevan's cases, that a great deal of the difficulty of breathing was not due to obstruction of the glottis, but from the general swelling of the mucous passages, extending to the smaller bronchial ramifications. He thought Dr. Bevan had struck the true chord in this matter, and that they had to deal with not merely a case of œdema of the glottis and obstruction from that cause, but with general inflammation, commencing in the lung, proceeding to the bronchial passages, and then to the smaller ramifications, ending ultimately in asphyxia.

Dr. BANON said that so far as he had seen these cases they confirmed the view Mr. Croly had expressed. He had not had any case of operation himself, but he had seen several operations, and he did not think he had ever seen one that was successful. There was one medicine which Mr. Croly did not mention, but which might be used with advantage, particularly where the child was delicate—namely, hippo, and it might be worthy of consideration whether it might not be advantageously substituted for tartar emetic in combination with mercury.

Mr. SYMES said they had extensive experience of this class of cases in Steevens' Hospital. He believed there

was no hospital in Dublin where so many cases of burns and scalds were treated; but so far as his experience went they had been altogether induced to trust to tartar emetic in these cases. In nine cases out of ten they were able within twenty-four hours to tell how the case would go, and in that short time they could not know how the mercury would act. Tartar emetic produced its effect in a few hours, and the result generally had been favourable. As to tracheotomy, he was inclined to look on it as the most fatal of all operations.

Dr. HAMILTON said there was a distinction in these cases which should not be overlooked—viz., one class of cases where the injury arose from drawing hot water from the spout of a kettle, and the other where it was caused by merely swallowing a hot drink. These cases were very different in the severity of the symptoms. He could corroborate the statement of Mr. Symes as to the advantage of tartar emetic treatment. It was now carried out systematically in Steevens' Hospital. Tartar emetic and calomel were given by the mouth, and mercurial ointment rubbed in, and general improvement was manifested before the mercury could act. The question might arise whether they might not get sufficient room by the operation of laryngotomy which he would prefer to tracheotomy, but he did not advance an opinion favourable to operative proceedings in such cases, for everything he had seen was unfavourable to the adoption of that course.

Dr. WHARTON could corroborate the opinion thrown out by Mr. Symes as to the efficacy of tartar emetic in cases of this kind. It was the ordinary method by which patients were treated at the Meath Hospital. Did Mr. Symes mean his observation about tracheotomy being the most fatal of operations to apply generally, or only when it was adopted in cases of this nature?

Mr. SYMES—In every case.

Mr. COLLIS suggested that in cases where tracheotomy became necessary, the tubing of the larynx might be substituted for those operations. By tubing a portion of the larynx, which was easily done, with a large-sized catheter, the patient might obtain a sufficient amount of air until the mercury, tartar emetic, or other treatment had time to act, and so operation became unnecessary. He presumed Mr. Symes, in condemning tracheotomy in the wholesale manner in which he had done, would except cases of laryngitis, where, except but for the operation, the patient would die.

Dr. KENNEDY observed that Mr. Croly mentioned that one of the children became salivated. Now, he had seen mercury often used with children, but he had never seen the gums affected; that they became red and swollen, as was the case with the adult. He thought mercury would act more rapidly than Dr. Hamilton supposed. He had seen mercury produce an effect, not on the mouth but on the disease treated, within twelve hours. He knew that in the way in which Dr. Law proposed to use mercury the adult could be brought under its influence in forty-eight hours, and there was no reason why it should not be quicker in its effects on children, in whom all the operations of Nature go on so much more rapidly. Therefore, in those cases in which tartar emetic had been used, he would not attribute the recovery altogether to it, but partly to the other medicines which were used. There were some cases in which the shock to the system was so great that he would hesitate before giving tartar emetic. The case might require wine and stimulants, and a medicine so powerful and depressing in its effects as tartar emetic might be found to be injurious. In one case which he had seen, mercury was used freely, and leeches were applied and the child made a rapid recovery.

Mr. CROLY, in reply, said he was glad his colleague, Dr. Geoghegan, had borne out what he had said in reference to mercurial treatment. His object in bringing forward these two cases was to elicit discussion. As to what Dr. Banon said about using hippo instead of tartar emetic, it must be remembered that in the case of the child Mooney, he gave no tartar emetic whatever. Had he done so it

would have killed the child, who was greatly collapsed when brought to hospital. He directed all his attention in the first instance to recover the child from the state of collapse. The use of antimony would depend very much on the stage to which the affection had progressed; and, unfortunately, mothers generally kept the children too long after the injury had been received before bringing them to hospital. The extracts from the surgical works, to which he had referred, while recommending the use of antimony, all wound up by recommending tracheotomy, showing that the antimony did not check the disease. He believed that mercury would salivate a child in eight or ten hours. He had seen so much of the effects of tartar emetic when given to children for croup, that he was getting afraid of administering that medicine to children. He had seen fatal results follow from it. He thought they ought not to give antimony, but depend entirely on mercury and stimulants, and treat the lungs and not the windpipe.

Reviews.

ON DISEASE OF THE RIGHT SIDE OF THE HEART.

By THOMAS MEE DALDY, M.D., M.R.C.P., late President of the Hunterian Society. Pp. 71. London: Bell and Daldy. 1866.

THE object of Dr. Daldy in writing this book appears to be to direct a greater degree of attention to be paid to the affections of the right side of the heart than that portion of the circulatory apparatus has hitherto received. He does not deny that the visible results of hypertrophy and dilatation have been carefully traced and described in the right as well as the left side of the heart, or that the diseases of the tricuspid valve have been overlooked; but he considers that many affections really due to morbid conditions of the right side of the heart have been unduly attributed to obstructive mischief in the pulmonary circulation or in the mitral valve. He believes that the muscular tissue of the right side of the heart is liable to the same alteration or deterioration of structure as that of the left side, without any mechanical obstruction as a cause, and that its diseases or defects produce corresponding morbid manifestations in distant organs, just as is done by diseases of the left side. To these propositions we think that very little objection can be offered, and we have carefully read the subsequent portions of Dr. Daldy's work, in which his views are amplified and illustrated by argument and by the description of cases. Our own impression is, that what is true in the theories or opinions advanced is not new, and that what is new is not yet sufficiently established to command general assent; but we do not insist upon the crudity of some of the statements put forward, because Dr. Daldy himself admits that his cases are too few to justify the adoption of any general conclusions, and that his reflections are offered in an imperfect form.

One great difficulty under which Dr. Daldy labours is that he has not always been able to confirm by post-mortem examination the accuracy of his opinions formed during the life of the patients; but this objection to the reception of his doctrines must not be overrated, because, as he very justly observes (and he quotes Andral as corroborating the observation), it does not follow because certain lesions escape the notice of the anatomist, that they do not and have not existed.

Dr. Daldy's main proposition appears to be that so far from morbid affections of the right side of the heart being subordinate in importance, as causing general disease, to those of the left, the right side suffers more than the left when its structure is impaired, because its texture is less in quantity, and therefore less able to resist the pressure sometimes exercised upon it by the venous circulation. This

impairment of function, caused by alteration of structure is, according to Dr. Daldy, the cause of many distressing symptoms, the true origin of which has not hitherto been sufficiently recognized, but which he thinks he has now traced, and he records the evidence on which this opinion is founded. As we have just stated, we do not think that Dr. Daldy has at present quite made out his case; but his reasoning is often ingenious, and his observations are sufficiently suggestive to stimulate further inquiry in the path he has indicated.

ON THE FORMATION OF ANEURISM IN CONNECTION WITH EMBOLISM OR WITH TROMBOSIS OF AN ARTERY. By J. W. OGLE, M.D., F.R.C.P., &c. London. 1866.

A SHORT paper has recently appeared on this interesting subject from the pen of Dr. Ogle. Having been led to consider the possible causes of the loud cardiac valvular bruit that arose and disappeared during the course of acute rheumatic fever, he goes on to observe, that though well aware that other explanations have been offered, he regards it as probably not infrequently owing to fibrine deposit on the valvular apparatus and its removal by the blood-stream as accounting for the disappearance of the bruit. If reabsorption of the fibrine takes place, no evil results; but Dr. Ogle has been led, by observations on a living animal as well as by human pathology, to regard the loosened clot when not reabsorbed as a subsequent agent in the production of aneurism; and it appears to us that his reasoning is quite justified by the ordinary physical laws which govern the human machine, and we regard the cases given by him as bearing corroborative evidence of the legitimacy of his views. "I cannot help thinking," he observes, "that in proportion as an aneurism occurs in a vessel which elsewhere and in every way is quite natural, and at a part where bifurcation exists, or subsidiary branches are given off (a part, *i.e.*, at which fibrinous particles would most likely be arrested in their transit), or in a subject free from other lesions of the arterial system, and of an age and sex at which aneurismal formations are least wont to appear—I say in proportion as these conditions obtain, I cannot help thinking that we have sufficiently reasonable grounds for conjecturing that a fibrinous plug, embolic or thrombic, may have been the ground of the mischief. This position would also be strengthened by evidence that the valvular apparatus, or some part of the inner surface of the heart, had been the seat of fibrinous deposit, or that the patient had been the subject of rheumatic fever." The author, in conclusion, appeals to other pathologists, hoping that their observations and experience may correct or substantiate his researches and suggestions on this highly interesting and important subject.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 2, 1866.

PREVENTIVE MEASURES AGAINST CHOLERA.

THE dreadful malady, the visitation of which has so long been threatening our shores, has made its appearance very lately in a ship on its passage from Liverpool to New York. The outbreak commenced a few days after the vessel left Queenstown, and is believed to have originated among some German emigrants who embarked at Liverpool. From a letter published in the pages of a contemporary, we learn that the ship, the *England*,

sailed from the Mersey on the 28th of March, having a few cabin passengers and 1059 steerage passengers, and the whole number of persons on board amounted to 1218. On the 13th April 110 deaths had occurred, the victims being chiefly among the steerage passengers, although some of the crew also died. The class of persons of whom the emigrants were composed was, we are told, of the lowest kind—"extremely dirty in their habits, all dressed in linsey-woollen clothing, and their diet consisted almost entirely of sour kraut that they had prepared before sailing; they actually refused the food provided for them on board the vessel."

Here we have presented to us the very conditions which are necessary to generate the poison of cholera, or at least to favour its development when atmospheric or other influences have called it into existence. The company of German emigrants, dirty, ill-fed, poor, and clothed in woollen garments, formed the best possible focus for the localization of the poison, and its subsequent transmission to persons previously healthy. The circumstances are in some respect analogous to those attending the terrible visitation of cholera last year in the East, when the disease broke out among the pilgrims assembled at some Arabian cities, and who were in pretty much the same condition as to personal habits with the German emigrants. When the *England* arrived at Halifax we are told that the sick were at once removed, some to tents on shore, and others to a Government hulk lying near.

The danger thus presented to us of a possible introduction of cholera into America or England is by no means to be disregarded; and we are therefore happy to find that the Government has issued the following notice to the local authorities at the various ports of the United Kingdom:—

"Privy Council Office, April 23rd, 1866.

"SIR,—I am directed by the Lord President of the Council to request that you will call the attention of the authorities at _____ to the communications which, by his lordship's instructions, were addressed to you from this office in August, 1859, and subsequently in July, 1865, soon after the cholera had broken out in Egypt and in Turkey.

"The progress which the disease has made in Europe since the date of the last-named letter, and the fact that, from information received to-day, cases of Asiatic cholera have occurred at Rotterdam and its vicinity, have again called attention to the importance of not neglecting any means of arresting the progress of the disease, if it should be introduced into the United Kingdom; and I am therefore, directed to reiterate the precautionary suggestions contained in the above-mentioned letters, and to repeat the expression of a hope that means will be provided for the reception and medical treatment of any poor seamen or other persons who may, on their arrival in this country, be found to be suffering from cholera.—I am, sir, your obedient servant, "ARTHUR HELPS.

"The Worshipful the Mayor."

At the same time it is to be hoped that all classes of the people, from the lowest to the highest, will co-operate in adopting measures for preventing the introduction of

cholera into this country, or of mitigating the horrors of the disease, if, after all, it should unhappily be introduced among us. While we earnestly advise the municipal and local authorities to attend carefully to all sanitary improvements which may be necessary in their respective localities, we would also warn the lower orders, if perchance our advice should ever reach them, to cultivate such personal habits as tend to the maintenance of health, and to avoid such excesses as are, we fear, too common among many who dwell in our crowded seats of industry. From the same source as that from which we learned the particulars of the mortality on board the *England* we are informed that in Liverpool, one of our greatest seaports, the excessive use of intoxicating liquors has become almost universal among the lower orders; and it needs no argument to prove that such habits must lead not only to individual misery, privation, and disease, but also to the spread of epidemic maladies, if they should by any chance be introduced into a community.

THE SICK POOR AND THE HOUSE OF LORDS.

It is a refreshing sign of the times that the condition of the sick poor receives any notice whatever in our Houses of Parliament, and it is still more gratifying to find that the sufferings of this helpless class of our fellow-creatures are beginning to excite something like sympathy from our Legislators. In fact, now that it has become fashionable to abuse the Boards of Guardians, we may expect that not only Peers, and Bishops, and Archbishops will begin to busy themselves about the treatment of the sick poor in workhouses, but we may hope that even Peeresses and other distinguished ladies will believe that these poor creatures are composed of the same flesh and blood as themselves, and will think that they deserve at least as much consideration as the inmates of more fashionable charities supported by bazaars and fancy fairs, and patronized by half the members of the aristocracy. Miss BURDETT COURTIS, indeed, has actually written a letter to the Board of Guardians of St. Pancras, expressing her abhorrence at the last sensation event occurring in the workhouse of that parish, and known as the laying-out case, on which, we may observe, quite as much capital has been made by the penny-a-liners as it deserves. But the St. Pancras Board are quite impenetrable to the remonstrances of Miss BURDETT COURTIS, as well as to the denunciations of the ARCHBISHOP OF YORK, and with a degree of independence and boldness, which would be honourable to them if shown in a good cause, they tell both the benevolent lady and the indignant divine either to examine the matter for themselves by personal inspection, or to mind their own business.

In the meantime, however, the agitation is kept up within the walls of Parliament, and we have independent members getting up in both Houses, putting questions to those in authority as to special instances of neglect or mismanagement, and receiving answers characterized either by total ignorance of the facts, by misunderstanding of the questions, or by equivocation of the truth.

The amount of cubic feet of air necessary for the respiration of a pauper seems to be a matter very imperfectly understood by the House of Lords, and we accordingly find a great amount of confusion of ideas prevailing upon the point, some noble Lords mistaking the amount respectively required for the tramps, or "casuals," and the able-bodied poor, and the sick poor; and others not unfairly contrasting the quantity of air allowed to a sick pauper and that which is authoritatively ordered for a healthy convict.

In a recent conversation in the House of Lords some questions were asked about the accommodation provided for the sick paupers in the Strand Union Workhouse, when, it will be recollected, a carpet-beating nuisance has long been allowed to continue, among many other inconveniences; and Lord GRANVILLE complacently informed the House that *no complaints had ever been made by the Medical Officers*, as to the neglect shown to the sick poor, and he then gave what he believed to be the cubic space of air allowed to each pauper. But it turned out that he confounded the tramp wards with the infirmary casual wards, as he afterwards admitted; and as for the absence of complaints from the Medical Officers, it is well known that the Surgeon of the workhouse has repeatedly remonstrated with the Guardians as to the ill-treatment of the sick poor, although for very sufficient reasons he has not ventured to make his complaints known to the Poor-law Board. If he had done so, he would in all probability have been dismissed from his situation and the Board would have taken part with the local Guardians.

The agitation on this subject is a very wholesome one, and is already producing some good effects, and among other small results we understand that the carpet-beating nuisance in the Strand Workhouse has been suppressed.

THE SANITARY IMPROVEMENT OF EDINBURGH.

OUR present energetic LORD PROVOST has set his heart upon lowering the death-rate of our metropolis, and his panacea for this is to drive streets through the most crowded parts of it, opening them up and letting in both light and air, but lessening the house accommodation. This has already been tried on a great scale in Paris; we are not aware, however, of any great reduction of mortality in that city, and we are certain that all previous experiments in that way in Edinburgh, however they may have contributed to the amenity of the town, have had no appreciable effect on its death-rate. To open up the most crowded parts of the city may indeed be a very certain mode of shifting the higher rates of mortality from one district to another, but unless accompanied by other and more important improvements, will assuredly have but little effect in reducing the gross mortality. Overcrowding is unquestionably one great source of endemic disease and of the spread of contagious disorders, but overcrowding is not caused by narrow closes and lofty houses, closes and houses in which the predecessors of our present nobility and gentry lived long and happy

lives? Certainly not. Poverty induces the huddling together of the present inhabitants of these closes for cheapness and for warmth, but poverty is not to be cured by open streets and free ventilation. Philanthropy may build workmen's houses, but while philanthropy not only does a good deed, but also lays claim to ten per cent. upon its outlay, it is powerless to check the present evil. Ninety-nine-hundredths of those inhabiting these overcrowded dwellings are, if not paupers in the legal acceptation of the term, certainly only kept from that condition by the aid of those many charities, which, flourishing in large cities, are preyed upon by its multitudinous and improvident poor. We are well aware that improvidence, intemperance, and disease go hand in hand, and that the root of these evils is intemperance, in its turn produced, if not resuscitated, by the depressing effects of vitiated air and bad or insufficient and innutritious food, while these in their turn are originated by poverty—a poverty which cannot provide a better house or better food, but which finds a temporary oblivion, if not a cure, for all these evils in the solace—debased and debasing, if you will, but still a solace—of drink. Is poverty to be cured by opening new streets and providing that better class of house accommodation which its unfortunate state of impecuniosity for ever prevents its making use of? Alas! no. The struggle for existence, in which now more than ever the many fail, and the altered circumstances of our commerce, now more than ever resulting in placing untold wealth in the hands of the few at the expense of the many; these producing as they do the concomitantly increasing helplessness and poverty of the many are the true sources of all the overcrowding of our wynds and closes with the resulting intemperance and high death-rate. And the cure for these evils is to be found, not in pulling down houses and opening streets, but in granting to the labouring classes a more liberal share of the profits produced by their labours, and by taking a more paternal interest in their well-being, by treating them, in short, as brethren, and not as mere hirelings whose lives are of less value than those of our horses, and whose comfort is of less importance than that of our dogs. These are matters that ought to be done, and yet the others ought not to be left undone; pay the labourer well, and provide him good house accommodation, and he will not only reimburse your outlay in rent, but in better work and decreased taxes, and though you may be deprived of the pleasure of laying the flattering unction to your soul that you are a philanthropist, you will at least be able to reflect that you have endeavoured to do your duty, which is what few would-be philanthropists attempt.

As medical men we have a deep interest in seeing that this movement is wisely directed; the heavy end of the burden falls upon us, not only in the loss of many promising lives by contagious diseases caught in the discharge of our duty, and caused by the failure of others to discharge theirs, but also in the

money loss accruing to our profession by the inability of these many poverty-stricken wretches to discharge our legal claims—claims which all above the rank of paupers ought to be able to meet, and which in regard to all in that rank are met by the State. The amount of charity thus extorted from our pockets is perhaps not incalculable, but is certainly an amount contributed by no other profession or trade in the universe. We may not give it in money, but we give it in money's worth, our time and skill—that whereby we live.

Not the least remarkable part of this peculiar crusade against the high mortality of Edinburgh is, that though we have a distinguished sanitary medical officer appointed and paid to look after the sanitary condition of the city, and who has displayed his fitness for his office by giving to the world an admirable volume upon that sanitary condition, yet, so far as we know, his opinion in regard to the probable sanitary results of the projected improvements has never been asked, and it has most certainly never been brought forward. Is it possible that the Lord Provost knows he is advocating a chimera, and that he fears to stultify himself and his conclusions by appealing to the only constituted and certainly the most competent authority upon the subject? Whatever the reason may be, this strange omission is not calculated to increase the confidence of the public in the soundness of his Lordship's deductions or the probable advantage of his proposals.

LUNACY ACTS (SCOTLAND) AMENDMENT BILL.

THE LORD ADVOCATE has just introduced into Parliament a Lunacy Amendment Act, with the provisions and omissions of which it is desirable that our brethren should be acquainted in order that if necessary some sort of consentaneous action may be brought to bear upon the LORD ADVOCATE for the purpose of causing him to alter some of these provisions which are objectionable and to repair some of these omissions which are indispensable. In the first place, Clause XIV. gives to Parochial Boards the power of providing buildings and other accommodation for the insane pauper poor, to this course there cannot be any possible objection theoretically. A board which is capable of taking care of sane paupers is, or certainly ought to be capable of taking care of insane paupers. Practically, however, this was not found to be the case, and the misery and bad management of the lunatic poorhouse wards of former days are glaringly depicted in the report of the Royal Commission on the state of lunatics in Scotland. Still, as even under the present law, lunatic wards in poorhouses may be sanctioned by the authority of the existing Lunacy Board alone, and as the present Bill proposes to prevent this being done without the sanction and concurrence of the district board, who may reasonably be supposed to know the wants and circumstances of each district, thus interposing the District Board as a buffer between the Parochial and Lunacy Boards, we think there ought not to be any

objection to a clause, the tendency of which will be to lighten the burdens of the ratepayers, and which is in so far an improvement on the present Act, as it prevents that being done, except in suitable circumstances, which can now be done in any circumstances on the authority of the Lunacy Board alone. Perhaps lunatic wards in poorhouses are a mistake, and we believe they are in all but very exceptional circumstances; nevertheless, in this respect, the Act as it now stands is more objectionable than this amendment.

Clause XVI. of the Bill allows lunatics to correspond *privately* with the Lunacy Board—their letters to be forwarded unpaid; this is already the law in England, but it is calculated to subvert the discipline of an asylum, and to foster distrust in the minds both of the patients and their relatives; it is therefore clearly no amendment, and decidedly objectionable. Moreover, to imagine the need for any such private communication, is not only to suppose the medical superintendents capable of neglect if not worse, but is also *de facto* an imputation of dereliction of duty on the Lunacy Board itself.

Clause XII. is also highly objectionable. This clause makes it incumbent on all persons in whose house lunatics may be temporarily placed, and who may derive profit from lodging them, to report their having such inmates to the Lunacy Board within fourteen days. Such an inquisitorial enactment would seriously interfere with the due professional treatment of many cases of slight temporary aberration of mind, in the course of which change of air and scene is often an important adjuvant, while this would, in many cases be decidedly objected to by the relatives if it could not be obtained without the publicity entailed by a notification to the Lunacy Board. Moreover, this clause would completely prevent the sending of any one of the numerous sufferers from transient attacks of insanity to hydropathic or other sanitary establishments without exposing them to the misery, annoyance, and risk of aggravation from official inspection.

Section XIII. prohibits the retention by any one, in his own house, although not for gain, of any person believed to be insane, without an order from the Sheriff or the sanction of the Board; and if the Board have reason to believe that such person has been so compulsorily confined to the house after one year from the commencement of the malady, the Board are to be empowered to make such representations as will ensure the removal of such patient to an asylum. Some such modification of the present Act is certainly required to prevent the recurrence of such dreadful cases as that of the murder at the Grange, near Edinburgh, but to extend this clause and the power of the Board over every case in which temporary confinement may be deemed advisable, is surely as uncalled as it certainly is inquisitorial.

These are some of the most objectionable portions of the present Bill, while its good points are—first, that it facilitates the admission into asylums of patients presenting themselves voluntarily for that purpose; second,

that it provides that in the case of private patients, neither of the two medical certificates necessary to procure the order from the Sheriff requisite for placing the patient in an asylum, shall be granted by any officer of the asylum in which the patient is to be placed; third, that the Sheriff's order shall not remain in force for longer than three years, after which the Medical Superintendent shall be required to grant a certificate on soul and conscience, and renewable annually, that the patient is unfit to be restored to liberty with due consideration to his own safety or the public welfare; fourth, there is also a provision that Parochial Boards may remove unrecovered patients, unless the Superintendent shall certify that *they are dangerous, or for any other specific reason unfit to be discharged*—a provision which ought to be extended to all lunatics, whether pauper or not, much inconvenience and danger to the public having been experienced by the removal of patients from asylums by their relatives long before they were safe to be at large.

Such are the main provisions of this Bill now before Parliament, and it behoves the members of our profession, each in his own sphere, to agitate for and against its satisfactory and objectionable clauses, inasmuch as what is favourable is for the good of their clients and their own comfort; while what is unfavourable will seriously interfere with the discharge of their duty to their patients. Our Colleges, as representing the heads of our profession, will no doubt take joint action in this matter, but the force and efficacy of that action will depend entirely upon the impetus given to it by the simultaneous action of the whole body. In this as in everything else union is strength, and in nothing ought that unanimity to be more strenuously exerted than in endeavouring to repair the omission from this and all previous Acts of any clause bestowing protection upon medical men from those reckless and malicious prosecutions occasionally raised against them by lunatics who have in some manner escaped from restraint. So long as the law of Scotland is that any medical man who grants a certificate of a person's insanity, as required by law, is not a privileged defendant; and so long as a person who has been confined by a Sheriff's warrant in consequence of such certificate, is not required, when pursuing for damages to prove that the certificate was granted without probable cause—*i.e.*, wilfully, falsely, or maliciously; just so long, the only safeguard against an annoying and ruinous prosecution will be to be found in steadily refusing to sign any such certificate. Every endeavour ought now to be made to get the Legislature, which requires of medical men the duty of signing certificates of lunacy, to give them protection in the discharge of that duty. We hold it to be incumbent upon the Legislature to do this, and if after fair representation it still refuses, we consider that the profession would be fully justified in adopting the favourite argument of the day, and striking work in regard to the matter of lunacy certificates.

DUBLIN HOSPITAL REPORTS AND CLINICAL LECTURES.

IN order to the maintenance of a well-regulated arrangement in this department of THE MEDICAL PRESS AND CIRCULAR we have to request that in future all communications enclosing or concerning Hospital Reports or Clinical Lectures may be addressed to Dr. Belcher at our office in Lincoln-place (Dublin). As our space is limited, and is not equal to the demands made on it at present in this Department of the Journal, it is only necessary to say to those gentlemen who so kindly second our efforts to advance the more practical parts of our profession—that no undue delay shall occur on our part in the publication of their papers, lectures, or reports.

LUNACY ACTS (SCOTLAND) AMENDMENT BILL.

THE Royal College of Physicians of Edinburgh held an extraordinary meeting for the purpose of considering the Lunacy Acts (Scotland) Amendment Bill, and agreed to the following memorandum, a copy of which was sent to all the Scotch Members of Parliament:—

1. The College has no objections to the continuance of the Lunacy Board for Scotland.

2. The College has great satisfaction in observing the introduction of a clause for the purpose of facilitating the admission of patients presenting themselves voluntarily into asylums, the necessity for which was pressed on the attention of Parliament by the College in 1864.

3. The College objects very strongly to clause xiv. of the bill, which gives to parochial boards the power of providing buildings and other accommodation for the insane pauper poor. The report of the Royal Commission on the state of lunatics in Scotland gave ample proof of the misery and bad management of such places. The reports of the Commissioners both in Scotland and England are full of statements opposed to them; large sums of money have been advanced for the erection of commodious district asylums, on the faith of the poorhouse wards for lunatics having been abolished, and yet this bill proposes to return again to an obsolete system which has met with all but universal condemnation.*

4. The College is of opinion, and has already urged on the attention of the legislature the necessity of extending the provisions of clause ix. of the bill to all lunatics, whether pauper or not. Many of the fellows can testify to great inconvenience and danger to the public being experienced by the discharge of patients from asylums at the request of their friends long before they can safely be trusted at large.

5. The College objects to clause xvi. of the bill, which allows patients to correspond *privately* with the lunacy board. The College is of opinion that the existence of any such law would foster distrust in the minds of patients in an asylum, and would be very subversive of discipline. The College earnestly entreats the legislature to pause before it enacts such a law.

6. The College also objects to clause xii. of the bill which makes incumbent on all persons in whose house lunatics may be temporarily placed, and who may derive profit from lodging them, to report their having such inmates to the Lunacy Board within fourteen days. If this becomes law it will seriously interfere with the due professional treatment of a number of cases of slight and temporary aberration of mind. In these cases change of air and scene is often of importance in hastening recovery; but these curative means would, in many cases, be objected to by the relatives, if they could not be enjoyed without notification being made to the Lunacy Board.

* The opinion of the Commissioners both in Scotland and England are printed in a separate paper to show how strongly the workhouse system is condemned by them.

7. The College is of opinion that it is incumbent on the legislature, which requires of medical men the duty of signing certificates of lunacy, to give them some sort of protection from reckless and malicious prosecutions raised against them by lunatics, whose reason may have been only partially or not at all restored. The College has no desire to protect medical men who either through carelessness, corruption, or malice, have signed certificates not borne out by facts; but it is of opinion that no prosecution should lie against a medical man unless the prosecutor is obliged to prove that the certificate has been signed without probable cause—*i.e.*, wilfully, falsely, or maliciously.*

If it be asked what protection the public have against the improper signing of such certificates, the College would point to section xxxviii. of the Lunacy (Scotland) Act (Vict. 20 and 21, cap. lxxi.), which it is not proposed to repeal, and which contains most stringent provisions, which can be enforced under the penalties of fine or imprisonment, against any medical man who either carelessly or falsely signs the certificate required by the Act.

The College begs to suggest the addition to the bill of some such clause as the following:—

PROPOSED CLAUSE FOR THE PROTECTION OF MEDICAL MEN FROM UNJUST PROSECUTIONS.

“The 14th section of the Act 25 and 26 Vict., cap. 14, is hereby repealed, except in so far as it repeals the 34th sect. of the Act 20 and 21 Vict., sect. 71, and in lieu thereof, any party applying to have any lunatic detained in any asylum, lunatic ward of a poorhouse, or house duly licensed for the reception of lunatics, may present a petition to the sheriff of the county where such lunatic is resident or may be found, or where the asylum, lunatic ward, or house be situate to be subscribed by the party applying for the same, accompanied by a statement of particulars in the form of Schedule C to the Act 20 and 21 Vict., cap. 71, annexed, and setting forth the degree of relationship or other capacity in which the petitioner stands to such lunatic; and such sheriff shall thereupon remit the said petition to two medical persons to be named by him (such persons being registered practitioners under the Medical Act), to see and examine the said lunatic, and satisfy themselves as to the mental state or capacity of such lunatic; and if such medical persons shall be satisfied that the petition should be granted, they shall report their opinion and the condition of the alleged lunatic to the said sheriff, and the sheriff may thereupon grant an order for the reception of the said lunatic into or detention in the said asylum, lunatic ward, or house, or if they shall think that the petition should not be granted, they shall report the same to the sheriff, who shall refuse the said petition, or make such other order as may appear expedient, in the form of B to the said Act annexed, or as near as may be to the terms of such form; provided that the two medical persons shall have no immediate or pecuniary interest in any asylum, lunatic ward, or house: And no superintendent of any such public, private, or district asylum or house, shall receive or detain any person as a lunatic therein, unless there shall be produced to and left with such superintendent, such order by the sheriff, dated within fourteen clear days prior to the reception of such lunatic; or if such order be granted by the Sheriff of Orkney and Shetland, within twenty-one clear days prior thereto: Provided that the superintendent of any public, private, or district asylum, may receive and detain therein, for any period not exceeding three days,

* The law of Scotland in regard to actions against medical men signing certificates of lunacy, is ruled at present by the decision of the judges in the case of *Strang v. Strang* (Report of Cases in Court of Session, second series, vol. xi.) In that case it was ruled, that a medical man who grants a certificate of a person's insanity, as required by law, is not a privileged defendant; and that a person who has been confined by a sheriff's warrant in consequence of such certificate, in pursuing for damages, is not obliged to prove that the certificate was granted without probable cause—*i.e.*, wilfully, falsely, or maliciously.

and without any order from the sheriff, any person as a lunatic whose case is duly certified to be one of emergency, by one medical person qualified as aforesaid; and no action at law shall lie against any medical person so acting, unless corrupt or malicious motives.

"The sheriff shall fix the fee to be paid to such medical persons to whom the petition shall be remitted by him; and such fee shall be at once decreed for by the sheriff, and paid by the party applying.—In name and by authority,

"JOHN SMITH, M.D., President."

RETROSPECT OF THE MEDICAL JOURNALS.

APRIL 28TH.

THE *Medical Times and Gazette* draws attention to Dr. Lankester's statement in reference to the increase of infanticide; his arguments have been made use of by foreign authors, who have improved the occasion and exaggerated the crime by making the calculation for the whole English population, whereas Dr. Lankester's figures were those furnished by a district in London. There is no doubt but that crime is infectious, and our contemporary regrets the publication of a statement, which may be wrong, but which might furnish the idea to many imitators.

Mr. T. Spencer has found that black oxide of iron—magnetic oxide—is about the best purifier of water. The process only takes a few minutes, just the time it takes to filter through a layer of roughly powdered oxide a few inches thick; it is inexpensive and lasts for years, the proper method of preparation consists in roasting red hæmatite with saw-dust, in commerce it is known under the name of "magnetic carbide." We cannot agree with the theory that it acts by converting oxygen into ozone; but it is an undoubted fact, that very impure water can be rendered sparkling, clear, and free from *even soluble* organic matter by coming in contact with this substance.

Mr. Edwards, the surgeon of the Cardiff Workhouse, who was supposed to have been instrumental in causing the death of two inmates by the accidental administration of poison, has been exculpated from all blame, it having been discovered, on post-mortem examination, that the deaths resulted from natural causes.

Another case of ovariectomy has been performed in Manchester by the aid of local anæsthesia by Dr. Richardson's method. The case of Cæsarean section in which the ether spray was used lately has turned out completely successful, the patient has returned to her friends.

A painful occurrence has occurred in St. George's Hospital. The question has very properly been raised by the Board of Governors, whether the new system of nursing about to be introduced, should be carried on in connexion with a religious sisterhood or purely on secular principles; a very warm discussion took place, in the middle of which Sir Frederick Roe died of apoplexy. This brings to mind the death of the famous Hunter, in 1793, in the very same place, under precisely similar circumstances, in the midst of an angry debate.

Dr. Richardson has lately described a new method of applying caustics and styptics to raw surfaces, in conjunction with the ether spray. He mentions two hæmostatic ethers, one prepared by dissolving tannin in absolute ether and afterwards treating it with xyloidine; this he terms the xylo-styptic ether. The other is prepared by dissolving perchloride of iron in ether; this is termed the ferro-styptic ether. He has also invented a caustic ether, by the combination of hydrofluoric acid with the ether. An ozonized ether when injected into an apartment in the form of spray, renders the atmosphere pure, and the presence of the ozone can be demonstrated by Schonbein's test papers.

The clinical remarks by Dr. Barlow are most valuable on the subject of intestinal obstruction; his experience goes to prove that if the lesion exists, in the upper part of the bowel the pain will be more severe, the vomiting will come on much sooner after constipation, and in fact all the

symptoms will be more acute and rapid than where the large intestine is the seat of the disease; but the principal point of diagnosis lies in the suppression of urine. When it occurs early, it is sure to mark the case as one of obstruction in the upper part of the small intestine. The explanation given is that the urine is not secreted, as there is no fluid in the alimentary canal retained long enough for the absorption of water into the circulation. He treats these cases with opium administered in full and repeated doses.

In alluding to the coming meeting of the General Medical Council, the *British Medical Journal* seems to regret the little good that has been effected by it, especially in the way of reforming our educational bodies.

Dr. McKeand of Manchester, publishes four cases in which he successfully removed a soft cataract by means of the suction curette.

A case of syphilis treated by syphilisation, under the direct superintendence of Professor Boeck himself, is reported by Mr. R. Dunn. The patient, however, died of the disease before a cure was effected.

The *Lancet* proceeds in a leader to review Dr. G. Johnson's work on cholera, which has created so much noise in the medical world.

The post of physician to the Charter House, having become vacant by the death of Dr. Babington, the principal physicians are called on to send in their names.

Dr. G. Johnson's lectures on delirium tremens are concluded. He does not approve of the digitalis treatment, and remarks that several cases of sudden death have been traced to its administration in large doses.

Dr. C. Fox draws attention to the sympathy existing between the auditory canal and the larynx. He sums up a very elaborate paper as follows:—

"1. The sympathy between the ear and the larynx, as well as the stomach, has been long known, although the majority of recent writers seem to have overlooked it.

"2. This sympathy is not manifested in every individual, but in about seventeen per cent., and seems to depend on a state of hyperæsthesia of the nerve which supplies the auditory canal.

"3. The nerve of the ear concerned in the production of this phenomenon cannot be a branch of the vagus, as Romberg and Toynbee have affirmed, but is in all probability a branch of the fifth cranial nerve.

"4. This sympathy is an example of a reflected or sympathetic sensation, in which the connexion between the nerves concerned takes place in the nervous centre.

"5. Cases occasionally occur where a cough is solely dependent on the existence of some source of irritation in the auditory canal.

"6. The explanation of the sympathy between the ear and the larynx enables us to understand the mode in which pain of the ear becomes occasionally a symptom of a thoracic aneurism.

"One of my chief objects in bringing before the notice of my professional brethren this sympathetic connexion is to introduce to them what may be called an *ear-cough*, and to strongly advise them to examine the auditory canals in all cases of obstinate cough, where none of the more frequent causes of this symptom can be discovered."

Mr. Munn of the Middlesex Hospital describes a new method of treating nævi. He dissects up the skin and nævus in the form of a flap, and snips off with the scissors the dilated vessels, replacing the skin and applying pressure.

All the journals allude to the formation of a sanatorium at Blackrock, county Dublin, in connexion with St. Vincent's Hospital. However Dr. Q. is wrong in stating that it is the first established in Ireland. The third report of the *Convalescent Home* will be found in *Saunders' News-Letter* of April 30th.

A COMMITTEE of the Lords of the Hon. Privy Council sat on Saturday, in the Council Chamber, Whitehall, on the subject of the cattle plague. The metropolis showed a decrease during last week of twenty-two cases.

DR. RICHARDSON'S SPRAY AND CHLOROFORM.

(Communicated.)

HOWEVER desirable it may be to produce local anæsthesia during surgical operations, without inducing complete insensibility, thus avoiding any risk which attends the administration of the agents effecting the latter purpose, yet now, when Dr. Richardson's spray has answered the most sanguine expectations formed of it as a local anæsthetic, it becomes a question whether chloroform is not a more humane anæsthetic. Since the first cultivation of surgery, many attempts have been made to produce insensibility to pain, and this had been done with a two-fold object. It is a well known fact that the idea of the surgeon's knife is terrible, and that apprehension often causes mental suffering more excruciating in sensitive organizations than the actual application of the much-dreaded instrument. The mind plays an important part in disease. Sense and fright produce depressing effects on the body, and they require something to neutralize them. Hence we welcomed chloroform as an agent that subdued this mental torture, and the steps of the operation and all its details were performed while our patient lay in a state of profound stupor, dead—1st, alike to pain; and, 2nd, to perception of what was taking place.

Dr. Richardson's spray causes less of sensation in the parts to which it is applied; but the mental faculties of the patient are not in abeyance, and the horror which the *armamentaria* of the surgeon inspires is not removed. The eyes may be bandaged, but imagination will conjure up pictures of the proceeding even more terrible than the reality.

These objections may be deemed pusillanimous, but that we have some grounds for them may be seen from the following case:—The operation was a minor one, cutting off a few warts from the penis. The patient was a young man whose manhood should have induced him to bear any pain and not shriek like a woman, yet such a specimen of the *genus homo* was he, that when placed on the table he refused to allow it to be done, crying out for chloroform, until eventually, after some time was lost in striving to persuade him that he would not feel any pain, he was held down *vi et armis*.

While the spray was being applied he continued his unavailing struggles, and it is now impossible to determine whether he cried from an over-excited imagination, actual pain of the operation, or from the coldness induced in such a sensitive organ as the penis by the action of the spray.

Being so long accustomed to the action of chloroform, it seems repugnant to our modern ideas to have to hold down a patient and be compelled to operate on a heaving struggling mass of humanity, when by a simple application we can subdue all muscular action, and operate calmly and leisurely, undeterred by cries or throes.

If we have such difficulty with a man, what must we expect with a female. We may anticipate hysterics and other disagreeable concomitants. We have offered these observations because the new agent is now on its trial, and its advantages and disadvantages must be fairly canvassed. It has the merit of ingenuity and is novel, but these are not sufficient recommendations for its superseding chloroform.

We have based our objections on the broad ground of the humanity of the two agents, but we have not entered into the question of whether it does deaden sensation in

deep parts, whether its application does not cause as much pain as the knife, whether it is not an expensive operation owing to the price of ether; these points we have assumed as settled, and our arguments would apply equally well to the instrument devised by Mr. James Moore, at the end of the eighteenth century, for compressing the principal nerves and thus deadening sensation, had it been as successful as it was ingenious.

Correspondence.

WE are not to be assumed to agree with the views of our Correspondents whose communications we insert for the purpose of affording opportunity for the enunciation of all shades of opinion in things medical. Our revision of letters is, therefore, confined to the removal of statements or expressions which we consider unsuitable or irrelevant to the subject in hand.

ON THE SYSTEM OF MEDICAL ASSISTANTSHIP. TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Were I to start with the assumption that the whole system of unqualified medical assistantship was radically wrong, such an assertion might be deemed too sweeping, as it has been so long sanctioned by the antiquity of time, and been virtually enrolled as a standard appurtenance of medical practice; yet this proposition would have some foundation in truth, if we consider the discontent which prevails amongst those concerned, if we reflect on the duties which those employed have to perform, and if we then contrast the qualifications which they possess to fit them for the manifold duties of the office.

While our Medical Council is striving to secure privileges to qualified men to suppress empiricism and elevate the status of the members of our Medical Corporation, their efforts are rendered nugatory, for medical assistants are *bona fide* practising beneath the ægis of the protecting care of the general practitioners of England.

This is one flaw in the system, and this must affect qualified men, for while principals can obtain unqualified assistants for salaries which are fit only for servants, they will not give possessors of diplomas adequate remuneration for their labour. It is a question of political economy. There is a demand and a supply, and owing to the number of unqualified assistants in the market, prices must remain at a low ebb until the spurious article is discovered, or until some crisis takes place.

When we consider the duties of the assistant, they resolve themselves into dispensing and compounding, prescribing, visiting, vaccinating, attending midwifery, accidents, &c., filling up the gap in the absence of the principal, and thus excluding the neighbouring practitioner. This last duty is a very important one, and oftentimes a hard-struggling young practitioner, an M.D., M.R.C.S., finds, to his chagrin, when called to a case of emergency, that Dr. —'s assistant is there, and, owing to professional *etiquette*, he is obliged to retire.

In these varied avocations are concentrated all the functions of a medical man; and then let us turn to the qualifications of those who perform these important duties.

Very often they are gentlemen who have never entered an hospital or attended lectures—assistants *pur sang*—but who have served an apprenticeship in the country, or men of one, two, or three years' standing at a medical school; and, surely, such a training is not a fitting criterion for such a post. Thrown into this position, they are obliged to make a little knowledge go a far way, to have the manners of gentlemen, and to dress as gentlemen—in fact, to ape the medical man; while they are snubbed by their employers, in receipt of salaries which barely maintain them, and involved in an everlasting cycle of employment, which allows them scarcely

an hour's rest. *Their position is a false one.* Hence the discontent which so widely prevails, the bickerings and the unpleasantness, the mutual complaints of principal and assistant; so that, in the words of one of our principal medical agents, "no unqualified man, unless he has a blot on his escutcheon, is willing to accept the situation."

The principal who looks after his pecuniary interests is willing to avail himself of their services, as he can palm them off on his patients, who are ignorant of what a diploma is, and are content if he is sent by their family doctor; but he cannot treat them as a fellow practitioner, for they are but the jackal attending upon the lion.

It is a pity that their position is not a better one, for many a student, a gentleman by education, &c., feels himself compelled, through the *res angusta domers*, to intermit his studies and rusticate for a time, yet cannot do so without a sense of degradation. We have yet to learn that to toil honestly for money in other departments, whether of profession or trade, is degrading; why, then, is it so in this case? But yet it is considered so.

"'Tis true, 'tis pity; and pity 'tis, 'tis true."

Assistants cannot be blamed for being placed in this false position; it is those who have thus exposed them as deserving of censure.

This subject, in the interest of the qualified medical men who accept situations, would be well worthy of the attention of the Medical Council. The system could be changed with mutual advantage to all interested. The legitimate duty of the unqualified assistant should be confined to compounding and dispensing. Thus his position would be defined, they could not receive a lower salary than they have at present, and they would not be the drudges they are, and the holders of diplomas would thus receive more fitting salaries, as the competition would be lessened.

Some change should take place. It but requires the amputating knife to sever the unhealthy parts, and restore the whole to health and vitality.—I am yours,

A LATE ASSISTANT.

THE EXAMINATION OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

DEAR SIR,—Your sense of justice will induce you to give me an opportunity of freeing myself from the accusations of falsehood with which "L.R.C.S.I." has sought to brand me.

"L.R.C.S.I." asserts that I stated that there are no grinders in Edinburgh; that no students grind for that licence; that no man ever goes in for the examinations of the Irish College without grinding; and that the examination in Edinburgh is not reputed to be easier than that of the Dublin College of Surgeons. Allow me to say that I made no such statements as these, and that if "L.R.C.S.I." once more will refer to my letter he will see that I did not.

Had I asserted the above, I *would* probably be guilty of making erroneous statements; but what I did say was, that I *did not know of any grinders in Edinburgh, that I never knew of a student to grind for the Edinburgh qualification*, and I expressed a curiosity to see the student who would face the examination of the Irish College without grinding. As to saying that the examination of the Edinburgh College is not reputed to be easier than that of the Dublin College, I cannot find in my letter where I asserted this.

I cannot conclude without a word of advice to "L.R.C.S.I.;" it is this—that when he again presumes to criticize, he should take heed that what he sets forth as quotations, be so in reality, and not the contortions of his own fancy.—I am, dear Sir, faithfully yours,

A STUDENT.

[Certainly the statements attributed to our correspondent, and those which he confesses to, are distinct without differ-

ence. What is the difference between a student (who was supposed to be informed before he wrote) stating that there were no grinders or grindees, and that he *did not know* of any? He has received a just rebuke for his ignorance of facts.—ED. M. P. & C.]

SAVORY AND MOORE'S REPTILE HEART SYRINGE FOR ENEMA AND UTERINE INJECTION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The woodcut of this instrument, and description, appeared in the *Lancet* of 31st March, and the following week there was a letter from a Surgeon showing that the instrument is not new, but is identical with that known as Higginson's, except that the barrel is elliptical instead of cylindrical. These instruments are not, in my opinion, good, inasmuch as it is impossible to eject the whole of the fluid which runs out after use, and making a slop. Is it fair or right to represent an old and inefficient instrument as a new invention and an improvement? I think not; and doubt if Messrs. Savory and Moore will add to their reputation by this last idea of theirs.—I am your obedient servant,

M.D.

THE LIQUOR ATROPIÆ.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you allow me to call the attention of your readers to the liquor atropiæ of the present Pharmacopœia. I have recently employed it on two occasions, and an extremely acute attack of inflammation of the eye was the result in each instance.—I am, &c.,

J. G. HILDIGE.

7, Upper Merrion-street, 26th April.

Parliamentary Intelligence.

HOUSE OF LORDS.—APRIL 24TH.

LORD REDESDALE, in moving to refer the West Middlesex Water Bill to a Committee of the whole House, called attention to the increasing quantities of water annually withdrawn from the Thames by water companies, and suggested that new districts should be required to obtain their supplies from other sources.

APRIL 25TH.

SMALL-POX IN THE ROYAL NAVY.

The Earl of ELLENBOROUGH regretted to see by that morning's intelligence from India that her Majesty's ship *Octavia* had put into Bombay with 175 men ill on board from small-pox. He wished to know what precautions were established to prevent small-pox in the Royal Navy?

The Duke of SOMERSET said the regulation in force was that no one should be received on board the Royal Navy who either was not vaccinated or who refused to be vaccinated. Where vaccination was necessary it was performed as speedily as circumstances would permit. With regard to the *Octavia* it was probable the disease was introduced by some coolies taken on board; and his information was to the effect that the disease had shown itself in a very mild form, and was not likely to extend.

HOUSE OF COMMONS.—APRIL 19TH.

THE CHOLERA.

Sir J. C. JERVOISE asked whether the attention of the medical officer of the Privy Council had been directed to a statement that the Emperor and Empress of the French had visited the cholera hospitals in Paris, and that M. Gustave Girard had made experiments in demonstration of the non-infectious nature of the cholera.

Mr. BRUCE said the attention of the medical officer of the Privy Council, along with the rest of the public, had been attracted to the act of courage and humanity performed by the two illustrious persons mentioned; and the medical officer was also aware of the very daring experiments which had been made by M. Gustave Girard; but in spite of those experiments it was by no means established that cholera was non-infectious. On the contrary, the precautions which were being at present taken by the French Government in

connexion with this subject justified the medical officer of the Privy Council in holding the opinion which he did.

APRIL 20TH.

CONTAGIOUS DISEASES BILL.

Lord C. PACER brought up the report of the select committee on the Contagious Diseases Bill, which was ordered to lie on the table.

CONTAGION OF CHOLERA.

THE Epidemiological Society has issued the following letter addressed to the profession:—

“London, March 1866.

“SIR,—In the event of an outbreak of cholera in this country, the first practical question for the consideration of the profession will be, how to make adequate provision for the reception and treatment of the poor when stricken with the disease; and what kind of accommodation should be preferred, as most calculated for the benefit of the patients, and least likely to endanger the public health. The public will naturally look for some expression of opinion on so important a subject to those who, from study and experience of the disease, may be in a position to give the results of their practical knowledge. The President and Council invite your attention to the three following questions, and would feel much obliged if you will favour them, at your earliest convenience, with answers thereto.

“1. Can persons suffering from cholera be admitted into the ordinary wards of general hospitals or infirmaries without danger to the health of other patients?

“2. Can cholera patients be admitted into special wards, set apart for the disease, in general hospitals and infirmaries, without undue risk of the extension of the malady to the other inmates of the institution and their ordinary attendants?

“3. Do you deem it necessary that special hospitals should be provided for the reception of persons attacked with cholera? and that such persons should not, on any conditions, be admitted into general hospitals or infirmaries?”

VERDICT OF MANSLAUGHTER AGAINST AN AMATEUR PRESCRIBER.

MR. TAYLOR, coroner, resumed an inquiry on Tuesday, at the Coopers' Arms Inn, Wakefield, relative to the death of Mr. Joseph Newsome, innkeeper, who had been poisoned under unusually distressing circumstances. Mr. Newsome for some weeks past had been suffering from a bad cold, which caused him very restless and sleepless nights. On Saturday night he was talking to the company at his bar about the trouble his illness gave him, and a young man named Rigg went away, saying that he would get him something that would do him good. He shortly afterwards returned with a bottle containing about six ounces of a light-coloured watery fluid, and told Newsome to take half that night, and half the next morning. Newsome followed the instructions given, became very drowsy, wandered very much during the night, and was so dangerously ill next morning, that Mr. Kemp, Surgeon, was sent for. The doctor, however, arrived too late to be of any service, the deceased shortly afterwards undergoing every symptom of death from the effects of a narcotic poison. A chemist and druggist named Dennison stated that Rigg came into his shop on Saturday, and asked for five or eight grains of quinine and six or eight drachms of opium. Witness told Rigg that half a drachm was a full dose under ordinary circumstances, but in such cases as delirium tremens a medical man might administer more. Rigg said the person for whom he wanted the medicine was labouring under some such complaint, and the witness added two and a-half drachms of laudanum to the quinine, and filled the bottle up with water. At Rigg's request he put a label on the bottle, giving directions for three tablespoonfuls, or about a quarter of the contents, to be taken every three hours. When Rigg returned to the public-house the bottle had no label upon it, and instead of following the directions of the druggist, and giving Newsome a fourth of the bottle's contents, he told him to drink off half. As regarded the statement of Rigg that the person for whom he intended the potion was suffering from delirium tremens, it was proved that Mr. Newsome had had nothing but tea and coffee on Saturday, and had not tasted three glasses of malt liquor or spirits for a month. The jury returned a verdict of “Manslaughter” against Rigg, but the coroner admitted him to bail.

RETENTION OF MENTAL VIGOUR IN OLD AGE.

DR. FORDES WINSLOW, in a letter to the *Pall Mall Gazette*, mentions the following, among other instances, of the retention of mental vigour at advanced years:—

“Lord Eldon died at the age of eighty-six. He remained in full enjoyment of his wonderful intellect until shortly before his death. Lord Kenyon lived to the age of seventy. His powers of mind continued up to the last moment unimpaired. Lord Stowell lived to the age of ninety. His mind was vigorous to the last. Lord Mansfield died at the advanced age of eighty-nine in full and unclouded vigour of intellect. A few days before this illustrious judge passed into eternity he heard his niece asking a gentleman who was present as to the meaning of the word ‘psephismata,’ which occurred in Burke's celebrated work on the French Revolution. The answer was that it was a misprint for ‘sophismata.’ ‘No!’ exclaimed Lord Mansfield, ‘psephismata’ is right.’ He then, without the slightest difficulty, quoted from memory a passage from Demosthenes in illustration of the fact. Dr. Johnson died at seventy-five. His last work, the ‘Lives of the English Poets,’ was written only three years before his death. Chaucer lived to the age of seventy-two, with an intellect in full and brilliant activity. Sir E. Coke died at eighty-two. The last few days of his life were spent in revising his numerous works, preparatory to their publication. Sir Isaac Newton published the third edition of his ‘Principia,’ with a new preface, at the age of eighty-three. The great Locke died at seventy-three, showing no decay of intellect. He was actively engaged in literary composition up to a few days of his death. Cherubini continued brilliant in conversation at the age of eighty. Gosse composed a ‘Te Deum’ at seventy-eight. Corneille at the age of seventy exhibited no failure of intellect. Waller composed when he was past eighty a beautiful poem, entitled ‘A Passage of the Ruin of the Turkish Empire.’ Titian continued to exercise his marvellous genius as an artist up to the age of ninety-six, when suddenly he died of the plague at Venice. Benjamin West painted his celebrated ‘Death on the Pale Horse,’ said to have been his best work, at the age of seventy-nine. At the age of eighty-three Cumberland, the Bishop of Peterborough, studied and mastered critically Dr. Wilkins's ‘Coptic Testament.’ Handel made his last public appearance at the advanced age of seventy-five. Lord Lyndhurst who has not long passed away, has adorned every debate with the most profound wisdom and judicial eloquence that has never been surpassed. That noble lord, on the night he retired upon his ninetieth year, addressed their lordships in a speech that riveted their attention for more than half an hour with the most perfect clearness.”

Medical News.

THE cholera has made its appearance at Ste. Brienne, in Brittany.

MR. J. W. CLARK, M.A., Fellow of Trinity, has been elected Superintendent of the Museums of Zoology and Comparative Anatomy at Cambridge.

THE Sanitary Conference at Constantinople has decided that lazarettos shall be established in the vicinity of certain towns in Asia Minor. One of these lazarettos is to be built on an island near Smyrna.

AN official notice has been published at Manchester ordering all dogs to be confined from the 23rd inst. to the 1st of October, and attaching a penalty to the non-observance of the order.

At a meeting of the guardians of St. George's, Hanover-square, held the other day, the appointment of Mr. H. B. Farnall, C.B., together with Dr. Smith, to visit and report upon the state of the metropolitan infirmaries was discussed at great length, all present being in favour of the appointment of Dr. Smith and against that of Mr. Farnall.

NORTHERN COUNTIES LUNATIC ASYLUM.—A meeting of gentlemen interested in the establishment of a Northern Counties Asylum for Idiots was held on Monday, at the Town Hall, Manchester. It was stated that the total sub-

scriptions already received towards the institution amounted to £27,000, and £50,000 would be required. The subscriptions from this city amount at present to about £2000.—*Manchester Courier*.

CHARING-CROSS HOSPITAL.—We understand that Dr. Willshire is likely to resign in June next the office of Senior Assistant-Physician, which he at present holds in this hospital. In that case Dr. Frederick Headland will occupy his place, and the vacancy thus created will have to be filled up. Dr. Julius Pollock and Dr. Tilbury Fox are spoken of as likely to become candidates for the post.—*Lancet*.

THE OPHTHALMOLOGICAL CONGRESS FOR 1866.—Professors von Jäger, senior, Arlt, and Gulz, as the official managers of the next Congress, to be held in Vienna, have issued a cordial invitation to the ophthalmologists of all countries, assuring them that a rich material awaits their inspection at Vienna, where every attempt will be made to render their stay profitable and agreeable. The first general meeting of the Congress will take place August 25th, at the Academy of Sciences.

A COMMITTEE which was appointed some weeks since to consider the question of nursing in St. George's Hospital have selected the sisters of St. Peter's Home to undertake the duty, and have assigned the following reasons for their choice:—1. The vicinity of St. Peter's Home to the hospital, and the intimate acquaintance with the working and details of the hospital which several of the sisters have already obtained; 2. That St. Peter's Home has no other charge of public nursing to interfere with or conflict with their attention to their duties at St. George's Hospital; 3. That the peculiarities of dress and discipline are not so marked as in some other cases; 4. That St. Peter's Home is under the personal and immediate direction of the Bishop of London, without whose sanction nothing is done or undertaken, and that the Bishop has written under his own hand to a member of the committee to recommend the sisters.

THIS unlucky Vaccination Bill fails in a twofold aspect. It leaves the population as much as ever at the risk of bad or ineffective lymph, and in the next place, supposing the lymph to be pure, makes no proper provisions for its employment. It allows a minimum of remuneration to the operation, which is tolerably sure to be the maximum in practice, and which will thus perpetuate the present system of under-payment. Medical men are among the most philanthropic of our race: but there is reason to fear that the present inadequate scale of payment, coupled with other drawbacks, leads to a very slovenly performance of a highly important public function. How else are we to account for the fact that in the course of the recent inquiries out of half a million of vaccinated children who underwent examination only one in eight was found to be perfectly vaccinated, and that in more than one-fourth of the cases the vaccination had been of a "very inferior" order? The poor-law reports of 1862, as cited by Sir R. Peel, show that out of 702,181 children born in that year, only 437,693 were successfully vaccinated. At this rate vaccination is little standard better than a farce.—*Standard*.

CLARE COUNTY ASYLUM.—This building, in common with the majority of those in Ireland the purpose of which is similar, has been erected on a site selected for its salubrity. The site consists of about forty acres of land within a mile of Ennis, at the northern side of the town. The building faces the south, towards which the ground slopes gently. The whole number of patients for which accommodation is provided is 260; and twenty-five feet superficial are provided in the day-rooms for each patient, and fifty feet superficial in the dormitories, the ceilings being twelve feet in height. The amount of the present contract, exclusive of boundary-wall, gate and other lodges, farm offices, baths, water-closets, and engineering works, is about £29,000; but it is estimated that when these additional works are completed, the total cost will amount to £35,000. It is expected that the whole will be completed within a year from the present date.—*Builder*.

THE BRITISH MUSEUM.—The accounts of the British Museum have been laid before Parliament as usual. Professor Owen reports the acquisition of 30,402 specimens in the departments, of natural history; room has been made for the exhibition of a selection from them, but the bulk

have been stored for exhibition and scientific applications when the required space may be obtained. Dr. Gray reports the acquisition of specimens which serve to show the changes that take place in the gradual development of the growth of species of animals, while some illustrate the slight differences which exists between allied species that belong to closely connected localities, thus exhibiting to students the variations that occur under these circumstances, which is a question of much interest and much discussion at present. All the departments have been enriched in the course of the year. The mineralogy department secured the collection of Colonel de Kokscharow, the most important addition to this department since the purchase of the Allan-Greg collection in 1860. Its value consists in the admirable series of Russian, and in particular of Siberian, minerals, which form the greater part of it. Such minerals are always difficult to obtain beyond the limits of the Russian empire. The topazes are especially splendid. The most remarkable addition that has ever been made to the collection of meteorites accrued to it in the past year by the arrival from Melbourne of the great mass of meteoric iron found at Cranbourne, near that city, and known in the colony as the "Bruce meteorite."

VACCINATION.—To prevent the chance of a syphilitic vaccination, Dr. Pacchiotti recommends the following rules:—1. Examine carefully the child from whom the lymph is taken. 2. Try to learn the state of the parents' health. 3. Choose, in obtaining the lymph, such children as have passed the fourth or fifth month, as hereditary syphilis, in general, appears before that age. 4. Do not use the lymph after the eighth day of the existence of the vesicle, as the lymph on the ninth and tenth days becomes dull by mixture with pus, which latter may be of an infectious nature. 5. In taking the lymph with the lancet, avoid hæmorrhage, as there is less danger with pure and transparent lymph. 6. Do not vaccinate too many children from the same supply.

ROYAL MEDICAL BENEVOLENT COLLEGE.—Yesterday evening the anniversary festival of this institution was held at Willis's Rooms, King-street, St. James's. Sir William Fergusson presided, and was supported by the presence of the most eminent surgeons and physicians in London; indeed, a list of those entitled by distinction to mention would read like a page from the Medical Directory. The dinner, which was provided by Messrs. Willis, was on a most liberal scale and admirably served. At its conclusion, and after the usual routine toasts had been given and warmly acknowledged, the chairman gave "Success to the Medical Benevolent College," and in doing so referred to the report of the institution which was distributed about the room, and which, as is generally the case in these charities, afforded the strongest proof, not only of its utility, but of its actual necessity. The College was founded, or rather first commenced, in 1851, as an asylum for medical gentlemen who, from ill-health, want of professional success, or other adverse influence, had sunk into poverty, and for the widows who may have been left in reduced circumstances. The objects which the College is now carrying out are threefold—first, to maintain an asylum in which a hundred pensioners, who must be duly qualified medical men, or their widows, are provided with rooms and with incomes graduated according to their necessities; the second object is to provide a school in which a liberal education is given to 200 boys, the sons of doctors, at least 40 of whom are maintained entirely at the expense of the College, while the remainder are charged at the lowest rate found to be practicable; the third and last benevolent effort of the College is to provide either annuities or occasional pecuniary assistance to medical gentlemen in distressed circumstances, or to their families, when such assistance can be granted without detriment to the asylum or school, which is ever regarded as the principal object of this charity. There are at present resident in the College at Epsom, 24 pensioners, each of whom is provided with three comfortably furnished rooms, an ample annual allowance of coals, and £21 a year in money. The full complement of 200 boys are now in the school, and in addition to these there are many day scholars who receive all the advantages of a first-class education on payment, but who are not necessarily the sons of medical men. The Council are, however, earnestly desirous of increasing the number of foundation scholars and of placing their maintenance and that of the pensioners upon a footing independent of the somewhat precarious support of

annual subscriptions. To this end they appeal to the public on behalf of a class of professional men from whom the country derive so much advantage at so little cost, and who, with so little regard to aggrandizement, and under so heavy a load of responsibility and actual danger to themselves and their families, do so much good almost unknown and almost unrequited. Sir William Fergusson brought these points of the report briefly but strongly before the guests. The best proof of the success of his appeal is to be found in the fact that between £600 and £700 was at once subscribed in the room towards the maintenance of the charity.

THE Italian Government has organized a complete system of meteorological observations, according to the system of the late Admiral Fitzroy.

THE Abbe Moigno has issued a French translation of Professor Tyndall's discourse on "Radiation;" and of Dr. Hofmann's lectures on "The Combining Power of Atoms."

THE county population of England and Wales, exclusive of cities and boroughs, at the 1861 census, was 11,427,755.

MANCHESTER AND SALFORD SANITARY ASSOCIATION.—The annual meeting of this association was held on the 17th inst., when the Bishop of Manchester took the chair. From the report read by the secretary (Dr. Morgan) it appears fever from overcrowding and impure air is greatly on the increase. 3788 cases are reported in public practice, mostly typhus; the deaths being one in eleven, or in true typhus one in six. Mr. W. Fairbairn, Rev. Canon Richson, Rev. J. D. Kelly, Dr. Noble, and other gentlemen spoke in praise of the Corporation of Manchester and the efforts of the association for their practical measures to improve the condition of the poorer classes.

OFFICERS of the HUNTERIAN SOCIETY FOR THE SESSION 1866-7.—President—Stephen H. Ward, M.D. Vice-Presidents—S. W. Devenish, M.B.; Sigismund Sutro, M.D.; Thomas B. Crosby, M.D.; D. De Berdt Hovell, Esq. Treasurer—William Cooke, M.D. For the Orator of 1867—W. Sedgwick Saunders, M.D. Librarian—Robert Fowler, M.D. Secretaries—H. I. Fotherby, M.B.; W. Allingham, Esq., F.R.C.S. Council—Robert Barnes, M.D.; Henry Blenkarne, Esq.; Thomas Brown, Esq.; Thomas Bryant, Esq.; P. Lodwick Burchell, M.B.; Thomas Mee Daldy, M.D.; Esquire Dukes, Esq.; J. Hughlings Jackson, M.D.; G. Lightenberg, M.D.; C. F. Maunder, Esq.; W. S. Saunders, M.D.; Alfred Smees Esq., F.R.S.

A RETURN has just been published of the acreage of commons and open spaces near London. There are 38,458 acres of these kinds of land within the twenty-five miles radius, and 13,301 acres within that of fifteen miles. In the home counties the apportionment is as follows: Fifteen miles radius—Essex, 3740 acres; Hertford, 477 acres; Kent, 1568 acres; Middlesex, 2218 acres; Surrey, 2295 acres. Twenty-five miles radius—Berks, 2 acres; Buckingham, 1022 acres; Essex, 5798 acres; Hertford, 3912 acres; Kent, 2601 acres; Middlesex, 2564 acres; Surrey, 22,557 acres.

THE BETHNAL-GREEN GUARDIANS AND THE POOR-LAW BOARD.—The Guardians of Bethnal-green have at last come to what they look upon as a final settlement of the matter connected with the late official inquiry at that workhouse with respect to the sudden deaths of aged pauper inmates. The reports of the cases referred to shewed that in one of the cases a pauper named Robert Scolly was admitted on an order, and was handed over by the official at the gate to a pauper wardman. Neither the paid nor the pauper official gave or saw that the newly-admitted inmate had the necessaries to which he was entitled, nor was his condition reported to the master, and in the morning he was found to be dead. A coroner's jury blamed the workhouse administration, and the Poor-law Board's inquiry proved that there had been gross neglect in the case, for the paid official at the gate gave evidence showing that he did not know such necessaries as beef-tea and stimulants were to be obtained in the workhouse after a certain hour in the evening. The judgment of the Poor-law Board was that the paid official, Cardwell, should be called upon to resign, or that he should be dismissed after the usual warning. The guardians, on having this communicated to them, referred the matter back to the Poor-law Board, desiring to be informed on what grounds the recommendation was made, to which the Poor-

law Board replied by referring to the previous communication. This answer was received by the guardians with some merriment, and they agreed to pass on to the "next business," thus declining to carry out the judgment of the central authority.

SURREY COUNTY HOSPITAL.—The election of honorary medical officers took place on the 17th inst., when Mr. H. S. Taylor, Dr. J. Stedman, and Mr. R. Eager were appointed; the assistant honorary medical officers, Mr. J. Morton, Mr. T. Butler, and Mr. Schollick, having been elected three weeks previously.

NORTHERN COUNTIES' ASYLUM FOR IDIOTS AND IMBECILES.—An influential meeting was recently held in the Town Hall, Manchester, for the purpose of promoting the establishment of an institution for the training and education of idiotic and imbecile children and young persons. The Mayor, Mr. Boker, took the chair. Dr. De Vitre and Mr. Harrison, from Lancaster, attended to give explanations of the scheme, which was started some fifteen months ago under the auspices of Sir J. Kay Shuttleworth, who on this occasion could not be present. The Bishop of Manchester, Sir E. Armitage, and Mr. Hugh Mason expressed sanguine expectations of the advantages of the plans of the promoters. Mr. Fernley, Rev. S. A. Steinhall, Rev. Canon Richson, and Mr. W. R. Wood proposed resolutions which were strongly supported, and a handsome subscription was announced. The amount from Manchester alone was above £2000. The institution is planned on the Pavilion principle, for accommodating 300 inmates, but is to commence with 200, the remaining accommodation to be extended when required.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

His Excellency the Lord Lieutenant of Ireland having graciously signified his intention to visit the College, on Thursday next, the 3rd of May, at four o'clock, the President, Council, and Fellows will assemble at the College, at a quarter to four o'clock, on that day, to receive his Excellency on his arrival.

BIRTHS AND DEATHS Registered and METEOROLOGY during the Week ending Saturday, April 21, 1868, in the following large Towns:

At the Royal Observatory, Greenwich, the mean height of the barometer in the week was 29'844 in. The barometrical reading decreased from 30'13 in. on Sunday to 29'62 in. on Thursday.

The general direction of the wind was S.W. and W.S.W. * The average weekly numbers of births and deaths in each of the above towns have been corrected for increase of population from the middle of the 10 years 1851-60 to the present time.

† Registration did not commence in Ireland till January 1, 1864; the average weekly number of births and deaths in Dublin are calculated therefore on the assumption that the birth-rate and death-rate in that city were the same as the averages of the rates in the other towns.

‡ The deaths in Manchester and Bristol include those of paupers belonging to these cities who died in workhouses situated outside the municipal boundaries. § The mean temperature at Greenwich during same week was 47'8 deg.

Notices to Correspondents.

W. W.—The notice is inserted.
M. T.—The card has been received.
The Harceian Society.—The notice has been received, and also the Report.
The Obstetrical Society of London.—The Report has been received.
Mr. J. L. Milton.—The paper has been received.
M. W. Stephens.—Either of the qualifications mentioned would not be sufficient to procure a Poor-law Medical appointment, one of them being considered only as surgical and the other only as medical, and a candidate must possess both.

REPRINTS OF CONTRIBUTIONS.

ARRANGEMENTS have been made in our printing department by which Communications to THE MEDICAL PRESS AND CIRCULAR of sufficient length may, at the desire of their Authors, be reprinted from the pages of the journal in pamphlet form. *Twenty-five copies of the reprint will be presented free of cost, and any further number at a small charge.* Contributors are requested to intimate their desire for the republication of their Communications, and to specify the number of copies required, at as early a period as possible, as otherwise the type will be broken up.

MEDICAL APPOINTMENTS.

LONDON.

ARMISTEAD, J. W., M.R.C.S.E., Assistant-Medical Officer to the Leeds Public Dispensary.
 CLEMENTS, G., M.R.C.S.E., Senior-House-Surgeon to the Royal Infirmary, Manchester.
 DOUDNEY, E., Assistant-House-Surgeon to the Kent and Canterbury Hospital.
 HICKMAN, WILLIAM, M.B., F.R.C.S., Surgeon for out-patients at the Samaritan Free Hospital.
 WATSON, SPENCER, F.R.C.S.E., Assistant-Surgeon to the Central London Ophthalmic Hospital.
 S. N. HARRISON, L.R.C.P.Ed., Surgeon-Accoucheur to the Kilham Lying-in Dispensary.
 EAGER, R., Esq., Medical Officer to the Surrey County Hospital at Guildford.
 SPEDMAN, J. R., M.D., Medical Officer to the Surrey County Hospital.
 Mr. T. L. LACK, Assistant to the House-Surgeon to the Chichester Infirmary.
 Dr. McDONALD, of Dalmellington, House-Surgeon to the Ayr, Newton, and Wallacetown Dispensary and Fever Hospital.
 H. S. TAYLOR, F.R.C.S.E., Honorary Medical Officer to the Surrey County Hospital, Guildford.
 W. S. WATSON, F.R.C.S.E., Assistant-Surgeon to the Central London Ophthalmic Hospital.

IRELAND.

H. S. KANE, M.D., has been elected Medical Officer and Public Vaccinator for the Antrim Dispensary District of the Antrim Union, vice M. Weir, M.R.C.S.E., who was elected, but declined the appointment.

POOR-LAW MEDICAL SERVICE.—VACANCIES.

ENGLAND.

Isle of Thanet Union.—Minster District; area 15,797; population 3479; salary £25 per annum. Also the Workhouse; salary £120 per annum.
Ongar Union.—Workhouse; salary £40 per annum.
Weymouth Union.—Portland District; area 3555; population 8468; salary £35 per annum.
Workshop Union.—Blyth District; area 7072; population 1660; salary £20 per annum.

Medical Diary of the Week.

WEDNESDAY, MAY 2.

HUNTERIAN SOCIETY.—7½ p.m. Council.—8 p.m. Dr. R. Bennett, "On certain Derangements of the Nervous System occasioned by Shock, especially in reference to Railway Accidents."
 OBSTETRICAL SOCIETY OF LONDON.—7½ p.m. Special Meeting of Council.—8 p.m. Dr. Thomas Radford: "Cases of Laceration of the Uterus."—Mr. Robert Ellis, "On Anæsthesia by Mixed Vapours."

THURSDAY, MAY 3.

ROYAL INSTITUTION.—3 p.m. Professor Huxley, "On the Methods and Results of Ethnology."
 HARVEIAN SOCIETY OF LONDON.—8 p.m. Mr. Berkeley Hill, "On a Case of Empyema with Fistulous Openings, Cured by repeated Evacuations of the Pus."—Mr. Haynes Walton, "On Detachments of the Retina, their Causes and Treatment, with Specimens."
 NATURAL HISTORY SOCIETY OF DUBLIN.—8½ p.m. Dr. E. Perceval Wright, F.L.S. "Note on *Scotopelia pili* (Temm.) Bp."—Mr. W. Hellicor Baily, F.G.S., L.S. "On Fossil Plants from the South of Ireland." Dr. E. Perceval Wright, F.L.S. "To exhibit some New Echinoderms, and a New Teredo."

FRIDAY, MAY 4.

ROYAL INSTITUTION.—8 p.m. Prof. Abel, "On Substitutes for Gunpowder."
 ARCHÆOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—4 p.m.

SATURDAY, MAY 5.

ROYAL INSTITUTION.—3 p.m. Professor Huxley, "On the Methods and Results of Ethnology."

A CLINICAL LECTURE

ON

THE ORIGIN AND CLASSIFICATION OF FEVERS.

Delivered in the Theatre of the Richmond Hospital on 24th April, 1866.

By J. T. BANKS, M.D.,

KING'S PROFESSOR OF THE PRACTICE OF PHYSIC.

GENTLEMEN,—It has been deemed expedient in arranging the course of lectures on the subject of fever, which has lately been inaugurated by our distinguished colleague, Sir Dominic Corrigan, that one lecture should be devoted to a consideration of the classification and origin of fevers. I confess, *in limine*, that I find it a subject difficult to treat so as to invest it with much interest, for were I to enter into long details of classification and nomenclature, I should, doubtless, tax your patience to no small extent. I shall, therefore, keeping this before my eyes, be as brief as possible, and merely give you a short sketch, which, however, I trust, may not be altogether unprofitable to you who are but commencing the study of this most important class of diseases. To some who honour me with their presence I cannot flatter myself with the hope that I can impart information.

It would be waste of time for me to dwell at any length on the importance of the subject of fever, the more especially when I address *Irish* students. I may, however, tell you that in the wide domain of medicine there is no subject of more absorbing interest, or which demands a more devoted study on the part of all who seek to qualify themselves so as to earn even the modest title of being "safe practitioners." That fever has received no ordinary attention is proved by the fact that it has engaged the studies of the most profound thinkers and the most successful cultivators of the science of medicine from the days of the Father of Physic down to our own time. To us whose lot it is to practise the healing art in this country, fever possesses a surpassing interest, for its treatment, not merely during periods of epidemic visitations, but at all times, forms no inconsiderable part of our daily work. With such opportunities for observation as *Irish* physicians have enjoyed, it would be strange if they had not largely contributed to the accumulated knowledge possessed of this disease, and in truth they have not failed in this duty.

The earliest record we have of fever is to be found in the "Epidemics" of Hippocrates, and in proof of the accuracy of his description of the *census* or *ardent fever*, it may be noticed that it accords with the fever now prevailing in Greece, and that the symptoms closely resemble those of the fevers of Eastern countries as described by various writers.

No attempt, however, was made to classify the fevers with reference to their etiology, for we cannot discover that Hippocrates recognized the effect of marsh effluvia, nor is there any mention of contagion—a circumstance which is remarkable, inasmuch as it would appear to have been a part of popular knowledge in his time, for Thucydides, in the description of the plague of Athens, manifestly refers to its contagious character.

In very early times, too, the necessity of separation of the sick from the healthy, with a view of checking pestilential diseases, was recognized but not acted upon, although fully carried out in endeavouring to arrest disease among cattle.

It has been supposed by some that the pestilential diseases of ancient times, sometimes appearing as pandemics, have found in modern times an analogue in our typhus—that, in other words, typhus is the plague of our climate.

There seems to be much probability in this opinion, for we find the diseases being generated under similar circumstances. A reference to the work of Hecker, the great historian of the epidemics of the middle ages, will satisfy you that the events which preceded the black death or the great mortality were such as, in a modified degree, preceded the epidemics of typhus in modern times, and even in this country. I have before stated that in the earliest periods no attempt was made at classification of fevers, but the accurate observers of ancient days soon became convinced of the fact that some fevers were produced by overcrowding and destitution, and that they were communicable from the sick to the healthy; moreover, that they presented characters which caused them to designate this class by the name of "continued fevers;" whereas others, which were not produced by famine or overcrowding, and which were not contagious, exhibited a train of symptoms totally different, and such as merited the appellation of intermittent. There does not appear to be any doubt that these two great classes of fevers existed from the most remote periods, and that the first has been the great scourge of our race at different epochs of the world. There is no ground for supposing that the third great class of fevers existed in early times—I allude to the exanthemata or eruptive fevers, although Krause has hazarded the opinion that variola and not bubonic plague, or pestilential typhus, was the disease described by Thucydides.

To come down to comparatively modern times, we find Sydenham, in his chapter on epidemic diseases, describes a fever which he terms pestilential fever, and which he says he will not definitely pronounce whether the name of *plague* be properly given to it, but that every one attacked with the true and undoubted plague presented the same concurrence of symptoms.

In the nosology of Sauvage, we find fevers thus classed—"Febres continuæ," febres remittentes, and febres intermittentes—and under the head plegmasiæ exanthematicæ in addition to the eruptive fevers, we find *pestitis*.

Fevers not being symptomatic of any local lesion, have been designated idiopathic fevers, to distinguish them from the pyrexia or the febrile state found in connexion with some local affections.

Cullen, by dividing continued fevers into synocha, synochus, and typhus, has given rise to much confusion.

The division of fevers into specific and non-specific is founded on the nature of the cause. In the first, the disease arises from the absorption of a poison; in the second, it is produced by some accidental exposure to the heat of the sun, or, it may be, the consequence of fatigue or indiscretion in food.

We may get an idea of what is meant to be conveyed by the term specific from a variety of examples which are familiar. The saliva of a rabid dog is capable of producing a disease by its specific action, so is the pus taken from a small-pox pustule; *albeit* in neither is there any appreciable difference from saliva and pus which do not contain any morbid agent.

There is no more interesting subject than a consideration of the effects produced by the absorption of some poisons. The selection which they exercise, too, is most extraordinary. You are no doubt acquainted with the specific effects of lead upon the muscles, or I should rather say on a particular set of muscles, and of phosphorus in producing caries of the maxillary bone. I might multiply illustrations, but our business to-day is with fevers. I cannot, however, refrain from calling your attention to a new disease which has for its cause the absorption of sulphuret of carbon. The symptoms of this disease manifest themselves in persons employed in the manufacture of vulcanized india-rubber.

In some instances, then, we have a morbid agent cognisable by the senses exercising its specific effects on the system, in others we can only judge of its existence by its specific effects. Fevers are produced frequently by material poisons introduced sometimes with intent, as in the case of the poison of small-pox, but in the greater number of instances the poison is conveyed from the sick to the healthy through the medium of the atmosphere.

The fevers which we meet in the wards of our hospital are in general produced by the absorption of a specific poison which exercises its influence in different ways; the poison of typhus, in producing a disease easily recognized by its general characters; the poisons of small-pox, scarlatina, and measles, by inducing a fever with characteristic eruption; and the poison of enteric fever, by the production of a fever with specific inflammation of the intestines—a disease totally different and easily distinguished from non-specific enteritis.

The continued fevers of our own country to which alone I wish to direct your attention at present have been classed under the head of "morbi contagiosi," excluding simple fever, the degree of communicability differing in a remarkable manner.

The terms "contagion" and "infection" have frequently been used indifferently, as if they conveyed precisely the same meaning, and much inconvenience has hence arisen. So much has this been felt that it has been proposed to use the word "communicable" as including both. Some would confine contagion to the transmission of a morbid affection from a diseased person to one or many persons by means of a material principle, the product of a specific elaboration. In illustration of what many understand by infection, the effect of marsh effluvia on the body may be cited. Numerous are the instances in which we are utterly unable to determine the manner in which diseases admittedly produced by the absorption of a poison are contracted. This is not only true of fever but of many other diseases. I have known this to be true of some cases of glanders in the human subject which have come under my notice in this hospital. Here is an accurate drawing of the appearance presented by a man who was the subject of this loathsome disease; the most searching inquiry failed to discover that he had come into communication ever so remote with a diseased horse.

To satisfy myself that he laboured under true glanders I caused some of the matter to be introduced into the system of a horse by inoculation of the Schneiderian membrane. In some days the horse showed that he had imbibed the poison, and he ultimately died of the disease. You may observe that the lungs of the horse present the same morbid appearance—viz., purulent depots, which are observed in those of man.

In connexion with this I may observe that the disease is occasionally transmitted in a most extraordinary and unexpected manner. Trousseau tells us of a young woman who was received into the Necker Hospital, in Paris, presenting all the symptoms of glanders; she had never had anything to do with horses, nor had she any communication with persons who had, but she was employed in plaiting horse hair, which had been imported from Buenos Ayres, and it was believed that the germ of the contagion had resided in the hair which came from South America.

That the tenacity of some morbid poisons is very remarkable is beyond doubt, but we may treat as apocryphal some of the statements as to the virus retaining its power of producing disease after the expiration of many years.

The power of poisons of different kinds to act on the living body so as to excite their specific action depends in a great measure upon the state of health and vigour of the recipient. This is exemplified not merely in fever poisons but in other cases. Take, for example, the effects of injuries received in the course of dissections; repeatedly are wounds inflicted on persons who happen to be in good health, and no injurious consequences follow, but if the person who is inoculated be in a favourable condition for the virus to act, then the consequences may be fatal.

In looking over some manuscript notes of my revered friend and teacher, the late Sir Henry Marsh, I found the description of his own case, which I make no doubt will be interesting to many, and which forcibly illustrates the truth of the statement I have made. He says that he was repeatedly wounded in dissecting bodies, some of which were still warm, others in every stage of decomposition, without sustaining any injury, but that when he received the scratch, which was so slight as merely to raise the cuticle, it was at a time of unusual exhaustion and fatigue.

I give you his own words, which pourtray in a very impressive manner the effects which sometimes follow the reception of a poison:—"In my own case a slight injury so quickly affected the constitution that in ten hours after it was sustained, I vomited, and after a restless night I rose fatigued and uncomfortable, feeling much languor, and with difficulty performing my usual business, the local inflammation all the while increasing gradually, and the axillary glands becoming enlarged. In twenty-three hours after the receipt of the injury severe rigors, preceded by vomiting, obliged me to go to bed and cover myself with a heap of blankets; the rigor lasted about an hour and a half. Now, the pain, tension, heat, and throbbing in the finger were almost intolerable, and inflammation, extending along the course of the absorbent vessels of the arm, began to develop itself. The local sensibility was so augmented that tepid water seemed as if it would scald me. Soon afterwards the arm was swollen to the axilla, and the absorbents were beautifully injected. The pain was such that enormous doses of laudanum could alone enable me to endure its intensity. After the finger had been laid open eight successive times, and after the application of an immense number of leeches, mortification stopped at the second phalanx; the tendon sloughed away as far as the middle of the palm, and the inflammation of the arm gradually and slowly subsided. During the inflammation the radial and ulnar arteries throbbled violently." He then goes on to observe that in consequence of mental excitement and bodily fatigue the constitution was strongly predisposed to assume a morbid action.

Repeated observation has convinced me that it is when mind and body are depressed the poison of typhus most surely strikes down its victims. If we investigate the origin of fever in the cases of medical men in this country who have fallen in the performance of their duty, we find that the poison has frequently found mind and body broken down by incessant and often ill-required toil. Under such circumstances the system is prepared, so to speak, for the reception of the morbid agent. Frequently the infected person is conscious when the typhus poison is taken in; I can recall the fact in my own case. In going my round in the Hardwicke Fever Hospital early in the morning and before breakfast, not being at the time in good health, I made a close examination of the chest of a patient labouring under typhus. While I was thus employed the patient was seized with cough, and I was so placed that I must have inhaled the sick person's breath. The odour was peculiar and intolerably offensive, and the remembrance of it became firmly impressed on my mind. I was certain that I had imbibed the poison, and the accuracy of my impression was proved by the fact, that after a latent period of three days I exhibited the usual train of symptoms which usher in typhus of the severest form. There is no doubt, then, that we can sometimes by the sense of smell become cognizant of the presence of a poison capable of producing disease, and there are persons who are endowed with such a power of smell, either natural or acquired, by education of the sense, that they can readily distinguish the odour of one animal poison from another.

This by no means agreeable occupation—an inquiry into the odours which emanate from the bodies of the sick—has exercised the ingenuity of some investigators, and they have favoured us with some strange information on the subject. The odour given off from small-pox has been compared to the smell of a he-goat; that of measles to a

fresh-plucked goose; scarlatina to cheese. The smell of plague has been compared with the odour of May flower, and that of typhus with a Cossack! That the typhus odour resembles ammonia I have often observed, and the best and most recent investigators agree in the opinion that it is a compound of ammonia. Probably the more intense the smell, the more operative the poison; hence the necessity on the part of the attendant to avoid inhaling this concentrated poison.

We have occasionally an opportunity of observing that more than one poison is received into the system at the same time—a fact which disproves the accuracy of Hunter's theory, and such a case you may have seen lately in one of our wards. A young woman, aged 19, presented the eruption of small-pox, and at the same time the rash of typhus. On admission she seemed to have small-pox in a very mild form, the spots being few and far between. On the third day the small-pox eruption not extending, we found an amount of constitutional disturbance quite unaccountable. Closely examining the case we satisfied ourselves beyond all doubt that the two diseases were present. The case has progressed favourably, and she is now convalescent.

In noticing the co-existence of the two poisons in this case, I may observe, that the variola was remarkable for its extreme mildness, and the typhus was above the average in severity. The benignant nature of the small-pox was noteworthy, inasmuch as the young woman had never been vaccinated. With respect to the claim of true typhus to be classed under the head of morbi contagiosi, there does not seem to be at present much difference of opinion. I believe all who have had experience will admit its contagious character, that the degree varies in different epidemics, and even in isolated cases, must be conceded. We know from sad experience in Ireland how fatal fever has been in our own profession, and how it has thinned our ranks. In these hospitals we have had to lament the loss of some of our most promising students, who, while acting as clinical clerks, have taken the disease.

The typhus of camps and prisons has been especially noted for its eminently contagious character. The fever which broke out in the prison at Rheims, in 1839, was of this nature; three physicians, six pupils, one pharmacien, one clergyman, twelve Sisters of Mercy, eight attendants, and four prison warders took the disease.

I have already referred to the tenacity of some poisons. Wunderlich bears witness to six months' tenacity of the poison in apartments which had been occupied by fever patients. Doubtless this and all the recorded examples of the poison refer to true typhus—the typhus exanthematicus of the Germans. I am satisfied that the doubts expressed by some observers as to the communicability of typhus owe their origin to the fact of the different forms of fever being confounded by many physicians until a very recent period, not that some did not in our epidemics of former times mark the difference which existed between true typhus and famine fever, &c.

With respect to the nomenclature of our fevers, believing that much inconvenience results from applying different names to the same disease, I think it would be very desirable if the names were fixed. I have no wish to alter well-established names sanctioned by long use, therefore I object to calling typhus "ochlotic fever," or enteric fever "pythogenic." I much prefer the term "enteric" to typhoid, the name given by Louis, or to the dothienenterie of Bretonneau. A few words before I close on the question of the identity or plurality of the fever poison. Time would not admit of my going into the question, and I shall only state, and think I shall have abundant opportunities of proving to you in the wards, that the fevers, typhus and enteric, are essentially different. You may see them, as I have, follow each other—a fact referred to by my friend, Professor Gairdner of Glasgow, and others, just as you may observe variola follow scarlatina in a case now in the Hardwicke. Having paid no ordinary attention to the subject, and having enjoyed ample opportunities for

observation, I have long since ranged myself on the side of those who believe in the non-identity of the two fevers. There is no more difficult process for the human mind than giving up long-cherished opinions, and this applies to medical theories and doctrines to an extent of which we ourselves are frequently unconscious. This may in some degree account for the fact that there are still a few honoured members of our profession who believe in the identity of typhus and enteric fever, or that they are mere varieties and have a common origin. The manner in which some physicians in the plenitude of their great and matured experience have come forward to avow the change which time has wrought in their opinion upon this subject, is worthy of all praise.

Some enthusiastic persons have asserted that continued fevers may be banished by attention to wise sanitary regulations, that as plague no longer exists in many lands in which it was once so rife, so the cognate disease, or its modern representative, typhus, may also be exterminated.

Be this as it may, we know that much can be done by preventive measures, and on the eve of an expected pestilence we observe a wonderful amount of energy displayed, but unfortunately these exertions are but spasmodic, and when the danger is no longer at our doors everything reverts to its former state, calling to mind the old tale of the Byzantines, who exhibited such pious fervour during the earthquake, but who lapsed back to their former evil practices when they felt the ground once more firm under their feet.

ON THE TREATMENT OF SYPHILIS.

By J. L. MILTON,

SURGEON OF ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

(Continued from page 27.)

In other and rarer instances this form of chancre is attended by bubo which does not suppurate, or if it suppurates does not yield inoculable pus. Here, however carefully induced, the formation of an abscess does not in any way arrest secondary symptoms. These are the cases so often triumphantly brought forward to support the doctrine that secondary symptoms follow every kind of chancre and bubo, but the two form of abscess are distinct *ab initio*, and the progress of the last described form proves in every stage how necessary it is to adhere firmly to those means which check suppuration.

It must be admitted that it is difficult to distinguish between these forms of bubo *except by the results of inoculation*. But if they are allowed to run their course unchecked, it will, I think, be found that in the first class the progress to suppuration is more rapid and painful. The second kind often goes a certain length towards subsiding, and is then called into activity by some imprudence on the part of the patient, such as a long walk, leaping, dancing, &c., when it proceeds to suppuration quickly and surely enough.

To hear some authors one might conclude that the bubo following soft sore is always solitary, and that of hard chancre always multiform, but such is not the case. I have seen two, three, and even four buboes suppurate after soft chancre. I attended a patient who had three on one occasion and four on another, both times from a simple sore. They all suppurated and some of them so badly that there was great difficulty in healing them at all.

Large florid excoriations or ulcers unattended by any marked thickening of the edges are for the most part promptly checked by the use of steel, which, I may here remark, is a most valuable remedy in nearly all forms of chancre except the indurated. Provided the steel be given in such a manner as to make a speedy impression on the system, I imagine it to be a matter of perfect indifference what preparation is used. The citrate, tartrate, tincture, and mixture of steel are all equally good; the grand point is, that the dose should be sufficient and sufficiently often administered.

Rest is one of the most important items in the treatment of this form of sore, and in none is it more necessary. Over

and over again I have seen cases in which no remedies proved of much avail till it was secured. If possible, the patient should be confined to bed for a day or two, during this time the chancre should be bathed every two or three hours, and lightly covered with wet lint and oiled silk. A brisk purgative may be given every two or three days with the best effect, and I know of none superior to a dose of colocynth and blue pill at night, followed by a dose of citrate of magnesia before breakfast.

Whenever pain harasses the patient sedatives may be administered. There seems to be no rule whereby we can estimate the dose to be given, except it be the severity and duration of the pain brought on by the ulceration; but I believe it may be laid down as an axiom that it is necessary to *quell the pain thoroughly*, and that till we do this we cannot check the ravages of the sore; indeed when the ulceration is rapid, the action of the sedative given is the surgeon's sheet anchor. As to the local treatment, I believe it is scarcely ever necessary to use anything beyond water dressing, though if the discharge be very profuse and the ulcer inclined to become sluggish, a mild astringent lotion is often useful.

If there be any form of sore in which warm aromatic dressings of laudanum, benzoin, myrrh, &c., are useful, it is in this and the sloughing chancre. Formulæ for such things have been accumulating ever since the days of Hippocrates, and perhaps modern research has improved little on the rude sagacity of ancient times. So long as these dressings possess aroma and warmth, and are so applied as to exclude the air, all the necessary indications seem to be fulfilled. The black and yellow wash are great favourites with some surgeons, but the benefit derived from their employment is often temporary and always uncertain. Indeed they seem to owe any efficacy they possess to the lime water, for which I have frequently exchanged them without noticing any difference in the effect produced. It may interest my readers to learn that Mr. Judd cured a case of phagedæna, which had lasted eighteen months, by applying a warm solution of pitch and opium,* and that Mr. Hunter† cured another, also of long standing, in a few days by giving forty drops of lixivium saponaceum night and morning in a basin of broth. M. Ricord has for some time used the stearate of iron as an application in those cases, forty parts of the salt being mixed with five of the essential oil of lavender; and M. Robert, in very obstinate ulcerations of the female organs, recommends styrax ointment; facts of more importance than hundreds on which memoirs have been written and evenings spent in discussing.

At other times phagedæna assumes a different aspect. The edges of the ulcer thicken, harden, rise up, and are undermined. The sore spreads in one direction and heals in another, now extending in breadth and again invading the deeper tissues, but always progressing, wearing out the patience of both the sufferer and his medical attendant. There is often little pain and the progress of the disease is frequently slow, but its duration seems almost indefinite. M. Ricord saw a case of this kind which, after going on for seven years, still yielded inoculable pus. Indeed it is very doubtful whether, if left to itself, it would heal at all in some persons until it reached the pubis, when its ravages spontaneously cease.

One of the chief obstacles to combat here, and one of the causes of this frightful persistence of diseased action, is the extraordinary perversity of many of these patients. Whether a certain kind of organism prone to phagedæna is accompanied by a peculiar organization of brain I know not, and the knowledge, if one possessed it, would only be an interesting fact for the psychologist, though it would not be so very improbable; but I do know that some of these patients are the most impracticable beings we have to deal with, and now whenever I see a patient of this kind I at once tell him that if he will submit properly to treatment

he will most likely be speedily cured, but that if he does not feel disposed to endure the necessary amount of discipline, he had better not make the attempt.

For generally, the free use of steel mixture, in conjunction with decoction of aloes, proves perfectly adequate to effect a cure. If it fail, we possess excellent remedies in dilute nitric acid, followed by iodide of potassium, both of which may be given in some bitter infusion or tincture, and both of which should be given with brisk purgatives. As to the local remedies, the yellow wash and protiodide of mercury seem to me as good as any that I have seen tried, but unless they are properly and sedulously used they will prove as useless as all others; the patient will try a fresh source of relief only to abandon it for some new freak, and by exhibiting an instance of the mutilation which phagedæna, aided by folly, can produce. However, that is his own affair, as the disease, even among those who have to contend with the disadvantages of want of comfort, of rest, and of proper diet, and who are exposed to all the vicissitudes of the weather, is not so unmanageable when treatment has fair play. Some cases may require several weeks to heal; in others, loss of substance has begun before the patient is seen, and before treatment begins to tell some further loss is sure to occur. But the fearful destruction often recorded in the history of this malady is the patient's own doing.

This obstinate form of sore, when once it has begun to throw up dense white edges, does not, so far as my experience goes, induce secondary disease, or at any rate only very rarely, whether it is cured soon or late, whether we check it or leave it to take its course. The other varieties of phagedæna are occasionally succeeded by secondary affections of a mild form, such as papulæ, impetigo, and alopecia, and on a superficial view it might appear that these affections are due to this more rapid healing of the sore—in fact, to its not being allowed to run its course and wear itself out. I have heard the argument urged, but it seems to me that it cannot possibly stand its ground. Ricord has shown that a sore is as capable of infecting the system at the fifth day after connexion as at any period of its existence, and this evidence must, I think, decide the question.

We now come to the treatment of sloughing ulcers. The word ought, I think, to be restricted to that sore which sloughs at a very early period without ulcerating. Although it is attended by great depression, Mr. Judd and other writers maintain that these are the cases which peculiarly call for bloodletting. I do not see how we can doubt that it did good, or at any rate appeared to do so, for Mr. Judd had ample opportunities of seeing the effects of bleeding; but there can, I think, be as little doubt that very opposite measures have produced results equally if not more gratifying, and there are very convincing proofs of its utter uselessness. For instance, Mr. Carmichael* mentions a case in which the patient was bled three times to the extent of sixteen ounces; the pain was relieved in thirteen days. As the pain will subside in less time than this without bleeding, it may be very safely assumed that the remedy had, here at all events, not much to do with the result. Some other writers restrict the use of such means to cases met with in robust healthy persons. Such cases, I fancy, must be rare. I believe that sloughing happens mostly among unhealthy, dissipated, or highly nervous people, and that when it is seen in a robust-looking person there is still something wrong in the health.

In sloughing sores I have generally found that small doses of morphia, given at short intervals with ammonia and ether, and the use of white bread poultices, with a little solution of chloride of soda (Labarraque's solution) to remove the factor of the discharge, will change the appearance of the chancre in from twenty-four to forty-eight hours. As to the quantity of the morphia, it should be such as to produce a decided effect upon the pain; it is frequently necessary to give as much as a grain or a grain and a half at first in the twenty-four hours. So soon as

* Solution of pitch ʒi., dried plaster ʒii., opium ʒi. "A Practical treatise on Arthritis and Syphilis," 1836, p. 187.

† Works of John Hunter, vol. ii., p. 350.

* Essay on Venereal Diseases, 1825, p. 188.

the pain, restlessness, and quickness of the pulse begin to yield the dose of morphia may be diminished, and generally, on the third day at latest, it is well to order a brisk purgative. This should be strong enough to bring away three or four loose stools; it should act on the liver as well as on the intestines, and not gripe the patient. Provided these points are kept in view, the choice of the purgative may be safely left to the surgeon. Black draught, decoction of aloes, compound jalap powder, and syrup of senna with tincture of rhubarb, &c. &c., if equally nasty are equally good; a lucky thing for the patient and surgeon too, for aperients are numerous enough to furnish inventive minds with a succession of fresh crops till medicine shall no longer be wanted, and there are so many different opinions as to their value that I suppose scarcely anything but an Act of Parliament could ensure uniformity.*

The diet should be light, warm, and unirritating. Heavy meats, such as pork and beef, strong malt liquors and spirits, rarely fail to make the patient worse; a moderate amount of light wine, such as hock, champagne, or manzanilla, or a little hollands and water, have generally seemed to me to succeed best. In the subsequent treatment I have found no remedy superior to the dilute nitric acid in the decoction of bark. If it disagree with the digestion, iodide of potassium may be substituted for it, though even when pure it has never appeared to me to act so well as the acid.

There remain those chancres which, soft at first, rapidly acquire during their progress a certain degree of hardness, which are readily inoculated, and are yet followed by secondary affections, and that rare form in which the sore is *excessively* small, heals very rapidly, and is followed by most destructive accidents—rupia, caries of the vomer and nasal bones, obstinate disease of the testicle, &c. This is not the place to discuss the question, whether the first are really mixed chancres or sores resulting from a virus being grafted on a chancre springing from a different virus,† a doctrine which I should think could not possibly be applied to this sore more than once in fifty times, considering how common it is, and how rare must be the chances of such an inoculation. I have here to do solely with the treatment, and I believe the only way to deal with both kinds of these sores is to treat them like indurated chancre.

Sores which are hidden from view, whether in the urethra, or behind a prepuce which cannot be uncovered, are, I think, best treated locally with injections of nitrate of silver, from two to five grains, to an ounce of distilled water. As much as possible of the discharge should, first of all, be washed away with warm water, and then the solution should be slowly and carefully syringed over every part in which by pressure pain and hardness are discovered. The syringe should have a silver tube quite an inch and a half long. Treated in this way, these chancres heal so easily, and so rarely become phagedænic, that I have often been tempted to think that *light and air must be necessary for the development of this process*, though I admit that some cases published by M. Ricord militate against this view.

When phymosis is present, and especially when it is due to congenital tightness of the foreskin, I can see no objection to cutting away the constricting ring whenever the patient will allow it, which is not often the case. When the edge is fissured and hard, owing to the patient having neglected it, excision will often save a long and tedious treatment, as great part of, not all the diseased structure, can be removed, and the foreskin when tight is not only a nuisance but a source of danger. As to the cut edges becoming inoculated with the matter from the sores, I

believe the chances of such a complication, if it can be dignified by that name, are overrated. In many cases we never get the chance of operating till the period of repair has begun and the sore is no longer inoculable. I have frequently operated at an earlier period, even when there was a great deal of pain and swelling, without any bad result; and, lastly, with anything like proper cleanliness, and the application of nitrate of silver to the cut edges and the points where the stitches are introduced, the first step towards inoculation should never occur.

In paraphimosis the case is different, the œdema and pain being so great that the surgeon abstains, and the patient shrinks, from cutting, except at the last extremity. The best practice seems to be to cauterize the sore, and then, if possible, to return the foreskin. Suspension of the penis and the free use of an evaporating lotion of ether and acetate of ammonia in camphor mixture, or of acetate of ammonia and diacetate of lead in elder-flower water, applied on linen, will often afford great relief.

The replacement of the prepuce is often a matter of great difficulty. If it cannot be effected by one fair attempt, when due care has been taken to cleanse the parts, compress the glans and draw the prepuce forwards, by unremitting traction, it will rarely yield to a second. Some surgeons, Fricke among the number, profess to have never failed. I have not been so fortunate or skilful, but I have the consolation of knowing that wiser men than myself have been baffled, especially when there was a large sloughing sore behind the constriction. In these cases perhaps the best plan is not to attempt the replacement till the ring is divided, for if after this we fail, the failure is not of so much consequence. Even those cases where the whole prepuce from the glans forward, except of course where it is attached to the frænum, is thrown off by sloughing, produce but very little shock to the system, and are followed by very slight deformity.

Chancres in women may be treated on exactly the same principles. The same escharotics, particularly the caustic soda, are to be resorted to; the smarting from its use is not more severe than in men. The speculum ought always to be used, and all possible care should be taken to prevent a chancreous surface from coming in contact with other parts. When the sores are so situated that the patient cannot reach them, they should be inspected daily by the surgeon and dressed by a nurse. Rest is even more necessary for women than for men, especially when the sores are seated near the fourchette.

It may be asked why mercury and iodide of potassium have as yet been scarcely spoken of, and whether the object of all this is to advocate the treatment of syphilis without mercury, which was already done years ago. To this it may be answered, that it was precisely on account of the great importance of these remedies that I preferred discussing them in such a manner as to allow of their bearing on the subject in hand being impartially examined without breaking the thread of the argument.

With regard to the power of mercury in hastening the healing of chancre in certain constitutions, perhaps the majority, there can be little doubt; but in many others there can be as little doubt that its employment is certain to be followed by the worst consequences—erethism, sloughing, disease of the bones, and shattered health. Indeed, so far as my experience goes, by much the greater number of instances in which the more dire results of syphilis—those fearful mutilations from rapid sloughing or intractable ulceration—are met with, occur in persons to whom mercury has been given in alterative doses so as to affect the system, either in primary syphilis or in the early period of secondary disease; and I am inclined to think that these results are almost certain to ensue if the mercury be given when there is any languor, wasting, or feverishness.

And the worst of it is, there is no guide as to which kind of constitution will bear mercury in the first stage and which will not. Thus it has been repeatedly given, and is still given, by many excellent surgeons—Mr. Lawrence, †

* I think the following formula will, upon the whole, be found to answer as well as any:—

℞ Pil. hydrarg.

Extracti hyoseyam, an., gr. iv.

Misce et divide in pil. ij. hora decub; sumend.

℞ Decoct. aloes. comp. ℥i. mane sumend.

† Mr. H. Lee, *Lancet*, 1866. Vol. i., p. 337.

believe, among the number—in sloughing sore. I had myself used it in two or three cases for this formidable affection, but my opinion of its efficacy was suddenly altered by an incident I shall not very easily forget, for, in conjunction with a very experienced surgeon, I as nearly as possible killed a strong, healthy-looking man with eight grains of calomel and about six drachms of blue ointment. Deeming one such experiment enough, I have not since tried mercury in sloughing sore.

As to the question whether mercury is really necessary in primary syphilis, it may be replied that the mercurialists themselves admit the possibility of every form of chancre being treated without it. Their objection is, that when simple treatment is trusted to, secondary symptoms happen so much more frequently than when mercury is given; and that though a patient treated without it may now and then escape secondary disease, such cases are too rare to form a basis of treatment; and that the safest plan is rather to look at the worst side of the matter, to be ever armed against the possibility of mischief, and rather now and then to prescribe a needless course of mercury, than, through over-confidence, expose one patient to years of suffering.

Modern research has pretty well swept away this plausible and once favourite doctrine from the class-room, but it is quite certain that among surgeons in general it is still firmly enough rooted. A very great number of men still give mercury for every chancre, believing that infection may follow any kind of sore.

Now, the soft suppurating sore, accompanied by inoculable bubo, sloughing sore, and hard phagedæna, being rarely if ever followed by secondary affections, obviously do not require mercury, while the soft phagedæna and its sequelæ—impetiginous and rupial eruptions, alopecia, &c.—generally get on much better without mercury in any form and at any stage.

There remain then only soft sores, or rather sores with very little hardening, small follicular chancres, the source often of the most serious mischief, as also perhaps of pseudo-syphilis and mistaken diagnosis, and the true hard chancre. Here mercury, in many instances, if perseveringly and judiciously given, effects a complete and lasting cure. But it is no specific, and when secondary symptoms follow, there is every reason to believe that its previous employment had no beneficial influence on the later affection, and that as much mercury will have to be given as if none had been used.

But suppose the surgeon considers mercury necessary, that he looks upon it as a specific, in what form shall it be given? by inunction, vapour, or internally?

There are men in large practice who still cleave to inunction. "Rub in" is their watchword. No mer, they say, ever cured more cases than the most staunch mercurialists. Benjamin Bell, Pearson, &c. &c., scarcely knew what failure was, and when they did fail, it was because they did not use mercury enough. But this practice has almost died out, its followers grow fewer and fewer every year, and those who linger must change or fall into the background. The present, and still more the coming, race of men would never stand the friction treatment; they would rather let syphilis run its course. To say the truth, there is not much to regret in the loss. The very men who practised inunction sat in judgment upon it. There can be little said against inunction that Pearson, Hunter, and others have not said in other words. But it was the best remedy, bad as it was, and to their thinking the only means of cure.

Shall we give it internally? There are plenty of authorities to warrant us in doing so, and as many to denounce the system as ruinous and useless. M. Ricord, who gives mercury in this way, and whose experience in this branch is almost without parallel, in the evening of his honourable career, tells us that the disease is only too often incurable when thus treated. Mr. Syme and Dr. Drysdale say mercury is simply a poison, and my own experience is that no drug ever yet did so much mischief, ever was so unnecessarily given, or ever raised such

specious but utterly delusive hopes of cure, as mercury given inwardly in syphilis.

Of all the methods ever yet brought forward of employing mercury, that by vapour, as practised by Mr. Henry Lee, Mr. Langston Parker, and others is, to my thinking, by far the best, and in the hands of such men, especially with the appliances of a hospital, it is a most potent means of cure, and generally a safe one; but simple and effectual as it is, I doubt if it will be generally employed in private practice, and if this difficulty will in any way improve our chances of doing away with mercury altogether, it is to be hailed as one of the greatest boons.

Of the value of iodide of potassium in primary syphilis little need be said. Except in indurated chancre and hard phagedæna, I have not been able to observe any marked effects from its use. Over both those, it appears to exert a certain amount of control, and, perseveringly given for a period of six or eight weeks at this stage, I am disposed to think it has the power of averting secondary symptoms. I possess notes of some cases in which I attended the patient for undoubted Hunterian chancre, where treatment of this kind was adopted, and where no secondary affections, or only very slight ones such as psoriasis of the palms of the hands, followed. I speak here *only of cases where I had repeated opportunities of satisfying myself years afterwards that there had been no constitutional affection of any moment*. No other evidence would be trustworthy. It seems, however, quite certain that such cases have occasionally been noticed where no iodide of potassium had been given, so that further proof would be required.

Some trials made with this drug may serve to show how little we can rely upon foregone conclusions in medicine. Towards the close of the primary stage, and before the outbreak of the secondary affection, the blood globules diminish, and as mercury causes a waste of these, it was thought that iodide of potassium might answer better in this respect. M. Diday (who was one of the first to put this idea in practice) and M. Robert admit that the attempt was a failure.

Treatment of Bubo.—As the bubo of indurated chancre rarely suppurates it is not generally requisite in the early stage to do anything more than simply bathe it with hot water. Perhaps at a later period, when there is a great deal of hardening, it may be painted daily with tincture of iodine, or when obstinate a small blister may be applied. The bubo accompanying phagedænic or sloughing chancre is also generally manageable enough; indeed it is often restricted to a slight swelling and tenderness of the gland.

But the buboes which follow soft sores are often formidable enough, and all who have had much experience of this disease must be quite familiar with the rapid painful abscesses and extensive ulceration, the intractable phagedæna and obstinate sinuses, which now and then show themselves.

As the first step towards those complications, the formation of an abscess followed by the admission of air into an unhealthy suppurating cavity, can certainly be to a great extent checked, if not entirely arrested, every effort should be made to allay the inflammation. By allowing it to go on *pleno vivo* the patient is exposed to the most unnecessary pain, confinement, and indelible disfigurement. Often after a bubo has burst and closed up, pus collects again, another opening forms, followed by a third or a fourth, till the groin is almost riddled with sinuses.

The list of evils does not end with filth, lameness, sinuses and scars. The ulcerating surface may be attacked with hospital gangrene or most alarming hæmorrhage; or an intractable ulceration may fasten upon it, and for months defy the most persevering treatment.

(To be continued.)

THE cholera has been raging at Diekirch for some days past with unusual violence. After carrying off numerous victims among the working class, it is now choosing its prey among the wealthier inhabitants.

COMMON CHOLERA.

By J. DOWLING, A.B., M.D., Tipperary.

A FEW further observations on common cholera, a subject which has been recently discussed in THE MEDICAL PRESS, may not be altogether uninteresting. Common cholera I consider to be a disease essentially of irritation and not of poisoned blood, and that this is the case seems manifest from the rapid convalescence which generally takes place when once the symptoms have abated, and from the fewness of those who succumb to its attacks. There is at least as wide a difference between common cholera and Asiatic cholera as there is between vaccinia and variola. The cause of irritation may be internal, arising from the presence of acrid or indigestible substances in the stomach and bowels, or it may be external, as cold or other depressing agencies, which bring on congestion of the abdominal organs. The disease is most common in the summer and autumn months when new food is coming in and the temperature most variable. When it appears as an endemic, it is often confined to a very small area.

The plan of treatment which I have adopted for this form of cholera and invariably found successful, is the administration of laudanum in brandy punch, and the application of hot bran poultices—one after another—to the abdomen. Thirty or forty minims of laudanum in a half glass of brandy, not more, made into hot punch may be given to an adult. If the first dose, as generally happens, be rejected by the stomach, another may be immediately given; but if that also be thrown off I deem it advisable to wait for half an hour or more before administering a third. The auxiliary means should, in the meanwhile, be attended to. Hot bran poultices as hot as the patient can bear, sprinkled with laudanum, should be applied to the abdomen in quick succession, hot jars kept to the feet, and the hands placed in hot water. The bran can be very conveniently applied in pillow cases which are generally at hand. At the end of half an hour, if no amendment takes place, the laudanum must be repeated, but afterwards it would be prudent to allow an hour or even a longer interval to intervene before the doses are repeated. Much of the laudanum, if the stomach continues disturbed, will of course be thrown off, so the quantity retained may, after all, be only a small proportion of the quantity administered. If one or two doses suffice to allay the symptoms, there is no advantage in pushing the medicine further, while the danger of so doing is obvious, though the tolerance of opium in this disease is much greater than is commonly imagined. An old woman with choleraic vomiting and diarrhoea will bear two or three drachms of laudanum in as many hours. To a young man who was attacked by vomiting accompanied by little diarrhoea, but who suffered from convulsions to an alarming degree, I have myself administered about six drachms of laudanum in about eight hours. This man, who was a policeman, whose attack might fairly be attributed to night duty, his comrades had plied with brandy until he was half intoxicated, without producing the least beneficial result. Before I was able to procure laudanum I had to wait two or three hours and in the interval I tried occasional drachm doses of sulphuric ether with no better result. Indeed I am not quite sure that the brandy and the ether did not aggravate the disease; at all events, he became worse and worse. This man, however, was so well the following day that he might have got up. The after-treatment consisted merely in the exhibition of two or three effervescent draughts and two or three doses of calomel. There is no great danger of congestion from the use of opium, for the warm stupes, the hot jars, and the warm covering will cause revulsion to the surface; but should any congestion or inflammation appear to be present, the practitioner will of course direct his attention to it after the more urgent symptoms have abated.

Dr. Johnson of London, has recently written on Asiatic cholera, and advocates rather the promoting than the arresting of vomiting and diarrhoea in that disease. In

common cholera vomiting and diarrhoea very often may be said to be the disease itself; in Asiatic cholera they are always only symptoms, and perhaps not the most dangerous. Persons, it is well known, die of Asiatic cholera without either symptom being present. But if it be the best mode of treatment of Asiatic cholera, to promote vomiting and diarrhoea—symptoms which of themselves are sufficient to cause death—on the ground of eliminating a poison so it would seem should we also imitate Nature in the treatment of small-pox and other exanthematous fevers, and leave nothing undone to promote the eruption on the skin—a mode of treatment which has long since been abandoned.

Proceedings of Societies.

SURGICAL SOCIETY OF IRELAND.—APRIL 20.

Dr. WILMOT, President of the College, in the Chair.

DR. FLEMING brought under the notice of the Society a man who was affected with Cruveilhier's paralysis. He thought it would be admitted that this was a case showing in a very marked manner that peculiar class of muscular atrophy, which was comparatively rare, as the result of injury. This poor man was a sailor from the age of twelve years. In the year 1864, when engaged on board ship and employed aloft, he by some means lost his hold and fell down some sixteen or eighteen feet on the deck. The fall was partly broken by the rigging, but he was seriously injured at the time. He was stunned and remained insensible for some hours after the accident, and was attacked with a peculiar distressing sensation in the neck, extending along the spine and each upper extremity. Notwithstanding this, after two or three days he recovered sufficiently to go through some of his duty, and he continued to perform his work, but under most aggravated sufferings, the pain being referred to the localities he had mentioned. Between two or three months afterwards he found from day to day that he was losing the power of his upper extremities, particularly about the shoulders, and it was remarkable that the deficiency in that power commenced in the upper arm and ultimately seized the lower and forearm, so that although he had to a certain extent lost the power of the upper arm, he was yet able to hold with a certain amount of control objects with his hand. The disease progressed, and the muscles became atrophied to such an extent that some were reduced to perfect bands; some were hardly traceable, even under the electro-magnetic current. The man was able to walk about, and able to support to a certain extent his head, but occasionally the head fell down on the thorax. In addition to the loss of power in the upper extremities, he might mention that sensation was peculiarly acute in some situations. In all it existed, but in some there was hyperaesthesia. This man was in the hospital at Carlisle, and was for a length of time under the care of Sir James Simpson, at Edinburgh, and in London under the care of Sir William Fergusson. [This man was then undressed and examined by the members.] Dr. Fleming observed upon the well-marked effect of this disease which the man exhibited. There was little more than a capsule of skin thrown over the bones without any development of muscle. The respiration was probably diaphragmatic. He particularly directed attention to the back part of the spinal column. It was rather improved since his admission to hospital. Then he could not bear the slightest touch, but now he was much less sensitive. The man was particularly accurate as to the history of his case; his intellect was perfect in every respect. He swallowed well. He could not bend or raise his arm, and when asked to shake hands did so by swaying his body round. When he came into hospital he could not bear to be touched in the right scapular region, but now he was much improved, and his head was held better up. The treatment in Edinburgh

was electricity, which he liked and which he thought did him good, and he used strychnine also. His principal annoyance was a difficulty in respiration which he experienced in the morning. Occasionally there was some little interruption to the free function of the bladder and some slight attempt at incontinence of urine. He had examined the urine and found it normal in quantity and in quality.

Mr. ARTHUR CROKER, Staff Assistant-Surgeon, laid before the Society

A LARGE SIZED CALCULUS,

which he had extracted by operation from a young patient in the General Hospital, on the 21st of last month. He was sent up from a country station with all the symptoms of calculus. There was very little distress, indeed, considering the size of the stone, the only prominent symptom being difficulty of micturition, and on the removal of the stone by the lateral operation they were very much surprised at the size of it. The age of the patient was 14. He used to pass a couple of quarts of urine at night.

The following are the dimensions, &c., of the calculus:—

Shape ovoid.

Long axis, 2 inches.

Short do., 1½ inch.

Weight before section, 1 oz. 5 drachms and 28 grains.

Section showed a nucleus and several laminæ. The nucleus was as large as a good sized bean, of rather irregular shape and rough surface, and formed of alternate white and dark laminæ, which were composed of oxalate of lime and lithate of ammonia. The layer immediately enveloping the nucleus was of loose structure and appeared to consist of phosphates; its exact nature was not ascertained. Surrounding the last mentioned layer and forming bulk of the stone there are a number of very hard, dense, and compressed laminæ, and composed like the nucleus of lithate of ammonia and oxalate of lime.

Mr. Croker finally observed that the case was progressing most favourably.

Dr. WHARTON read the following case of

STRANGULATED FEMORAL HERNIA, TREATED ACCORDING TO PETIT'S METHOD.

Reported by Mr. JOHN J. MARSHALL.

Margaret McDermott, æt. 56, the mother of three grown-up children, was admitted into the Meath Hospital on 25th January, 1866, under the care of Mr. Wharton. The patient had been previously visited by Dr. Moore of No. 3, South City Dispensary, who, on having ascertained the nature of her case, directed her to seek immediate admission to the hospital. Her occupation is that of a huckster, and also of a washerwoman, which latter involves the necessity of lifting heavy weights. For six months previous to the above date, she had noticed a soft swelling as large as a "goose egg" in her right groin, which disappeared on her lying down, or on being pressed with the hand. On walking quickly she experienced "a tightness" and "cutting pain" at the neck of the tumour, but while sitting, standing, or even walking at a moderate pace, no pain whatever was complained of. On the evening of the 24th January, after a hard day's work, she observed a tumour, about the size of a large walnut, at the left groin, which was attended with a cutting sensation. On the same day her bowels were slightly moved, she felt very sick and ate but a little toast which remained on the stomach. She slept none during the night. On examination it was found that the case was one of double herniæ, that on the right side being inguinal and reducible, while that on the left was femoral and strangulated. The ordinary symptoms of strangulation—nausea, vomiting, thirst, dragging sensation from the umbilicus and constipation—having been present, measures were immediately taken to reduce the tumour, but without effect.

A consultation was therefore held, after which it was decided to perform herniotomy without delay. Chloroform having been administered and unavailing efforts having

been made under its influence to effect reduction, the operation was performed as follows:—A fold of integument having been held up was transfixed at the base—proceeding not always free from danger—and divided upwards so as to form an incision of about one and a half inches in length in a vertical direction, and occupying the internal site of the tumour. This incision exposed a large quantity of adipose tissue, which, along with the coverings of the hernial sac, was divided in the usual way. Scarcely any bleeding took place. On reaching the sac, which presented an uninfamed appearance, search was made for the stricture which was easily reached, and divided. This stricture, appeared to have been formed by a portion of the falciform process of the fascia lata. Renewed attempts were now made to return the intestine, but to no purpose. Further exploration was therefore necessary, and on introducing the finger *deeply*, and in a direction almost at right angles to the plane of the abdomen, a second stricture, was discovered to the inside of the tumour, and in the situation of Gimbernat's ligament. On its division, it was found that very gentle pressure on the hernial sac caused the ascent of the intestine, and by a continuance of the pressure and gentle manœuvring, the sac itself was easily made to follow. The wound was dressed by means of silver sutures, the application of a large pad and spica bandage, when the patient was removed to bed, which was previously warmed.

The daily treatment and condition of the patient, although fully reported by Mr. Marshall, need not be detailed. It will be sufficient to state that perfect recovery without any interruption, save a rather sharp attack of diarrhœa, took place, and that the treatment consisted mainly in the exhibition of sedatives, of which opium in the form of Battley's liquor (for which, however, tinct. of opium was substituted during the attack of diarrhœa) formed the chief element. This drug was continuously given for several days. On the fourth day after the operation four grains of calomel were prescribed, which were followed after an interval of a few hours by a rhubarb draught. Hydrocyanic acid was directed in two-drop doses at the commencement of the treatment and continued so long as there was any tendency to nausea. The diet was light and nutritious but abundant. Brandy diluted was exhibited frequently in small quantities at the outset, and subsequently wine to the extent of from four to six ounces per diem. Mercury formed no part of the treatment except on the occasion mentioned above. The wound granulated and cicatrized so firmly that, on directing the patient to cough, no yielding at the situation of the wound could be observed or felt, while the hernia at the right side was instantly reproduced. The patient left the hospital in perfect health, having been provided with a double truss—an instrument of which she had never heard the use.

My object in occupying the attention of the Society on this evening, is with a view of canvassing the opinions of its members as to the propriety or otherwise of reducing a strangulated hernial tumour *en bloc*, and of soliciting their experience on this subject—a subject not new to the Society, but not, therefore, the less interesting. The question is one of much importance and has engaged the deserved attention of surgeons. The duration of the strangulation, measured as it were by the tightness of the stricture, forms no doubt a very important item in the account, but yet it is not a sufficient guide. In the case before us the hernia which was strangulated, was not more than twenty-four hours old, if so long. The strictures, however, were so tight that it was by no means easy to introduce my fingernail under them, and very considerable difficulty was experienced in the insinuation of the extremity of Cooper's knife. Again, the tightness of the stricture must be as I imagine a more or less uncertain test, as the effects will probably depend upon the nature of the contents of the intestine and the condition of the sac itself. I am not myself aware *positively* of any circumstance which can be raised or considered as a direct objection to this mode of operating, unless it be that the impediment to the return

of the intestine depends upon a cause within and not external to the sac. There are some surgeons, however, who hold a contrary opinion, and that for reasons rather, as it appears to me, of a theoretical than of a practical character. Professor Hargrave, who deserves the thanks of this Society for his introduction of the subject to the notice of its members, has enumerated these objections, and as I think fully answered them. The discussion which ensued, and which will be found in the twenty-ninth volume of THE MEDICAL PRESS, cannot, I think, be considered as favourable to the operation, an effect attributable to the hypercriticism bestowed upon Mr. Luke's statistics (as brought forward by Professor Hargrave), but which in my mind are sufficient to settle the matter for ever, proving, as they do, that the results of his practice are marvellously successful. Let it be granted, that the intervals between the strangulation and the operation have been left unnoticed, upon which point the discussion chiefly turned. Yet this omission in no respect interferes with the credit due to him on account of his advocacy of this method of treating strangulated hernia, or with the singular results which he has experienced and published. Further statistical information will be found in a communication published in the thirty-second volume of the *Dublin Quarterly Journal* by Mr. Maurice H. Collis, in which he gives a successful case of herniotomy without opening the sac. In this paper a comparison has been instituted between the mortality from herniotomy according as the sac has or has not been opened. The result is altogether in favour of the latter, in which the death-rate is something under thirty per cent., whereas in the former it amounted to about fifty. The operation is one which met with much opposition on the part of some of the contemporaries and successors of its author, Petit, who, however, with due perseverance maintained its propriety, and concluded that "with the exception of gangrenous herniæ, those in which the intestine is loaded with scybala, and some of those in which the intestine contains foreign bodies, all others may be treated in this manner; there are some even which should not be treated in any other way." Mr. Bryant, in his analysis of fatal cases of herniæ, as published in the second volume of "Guy's Hospital Reports," third series, states that, with regard to the great question of opening or not opening the sac, the conclusions bear a decided tendency towards the latter operations, though more perhaps by negative than positive evidence, and as the results of his analysis, states that even gangrenous intestines should not be admitted as an objection to the operation, but rather the contrary. The operation would not have maintained its present status had not the second Munro almost, if not altogether, as an original observer, directed attention to its advantages. By means of experiments upon animals, he found that the contact of air with the peritoneum, as also the handling of the latter, were of themselves sufficient to bring about a fatal issue, and to this cause did he attribute the mortality incidental to herniæ operations. The results of his practice confirmed his views. Sir A. Cooper afforded a moderate support to the proceeding, chiefly on the ground, as far as I can understand, that if the epigastric artery were divided the hæmorrhage would escape externally; he also recommended its adoption in large herniæ, where there is no constriction of the neck of the sac, and also in small herniæ, in which it is possible and desirable to return the sac into the abdominal cavity. He was of opinion, however, that it would be gradually introduced into general practice, when it has been fairly tried, and found, if performed early, to be free from danger and attended with no unusual difficulty. Sir Charles Bell and Bransby Cooper advocated its adoption; the latter indeed upon principle, as, according to him, the stricture is much more frequently dependent upon the parts external to the sac than upon the sac itself. Mr. Lawrence also generally approves of the operation; but his commendation may be described as lukewarm, for he hesitates to recommend its adoption unless unequivocal advantage should be found in the proceeding. To Messrs. Key and Luke is to be ascribed

the position which the operation now holds in surgery. It has been stated that the operation is difficult of performance; but it may fairly be asked, will the opening of the sac render it less difficult? So far as the division of the stricture is concerned, it is more likely that this can be more easily effected, and with less risk to the patient, without opening the sac. It appears to me that in all cases it would be for the interest of surgery were it to be considered as a rule, that the sac should not be opened until after the division of any external stricture which may be within reach, and should this fail to give the desired relief, then will be the time to have recourse to any ulterior proceeding which the urgency of the case or the wisdom of the surgeon may dictate. In the case which has occasioned these remarks I had no difficulty to deal with after the division of Gimbernat's ligament, the intestine almost of its own accord, so slight was the pressure made use of, returned to the abdomen, and the sac may be said to have been in a hurry after it. Had it been otherwise it would have, no doubt, been necessary to have opened the sac for the purpose of releasing the intestine from any adhesion or other hindrance to its return. So far as the Meath Hospital is concerned, I am happy to state that the operation is in much favour in that institution. Mr. Macnamara adopted this method in a case in which he operated on 31st March last. The patient is in a most satisfactory state up to the present date. Mr. Porter also performed a similar operation so recently as on the 5th inst., and with every prospect of success.

Dr. BAXON wished to know if Mr. Wharton confined his recommendation of this operation to femoral hernia. He presumed that he did not advocate it in cases of inguinal hernia.

Mr. STAPLETON looked on this operation as principally relating to femoral hernia. He quite agreed that it was not difficult to perform the operation without opening the sac, but from his experience he believed that in chronic cases particularly, although there might be a stricture besides that connected with the sac, the sac was generally the constricting part, and when it was opened the assistant should take a portion of the sac and pull it down, for he had known the intestine to go back and to be strangulated in the sac, and in chronic cases there was a great thickening of the neck.

Mr. COLLIS said it was now some years since he had first ventured to speak on this subject, and at that time there was not a single person to say a word in favour of the operation but Professor Hargrave. The mortality in the cases in which the sac was not opened amounted only to 14 per cent. The mortality in cases in which Petit's operation was performed in its integrity—that is, where the sac was not opened and the strangulation was removed without any injury to the peritoneum—was only 14 per cent.; but in these cases where it was found not possible to return the intestine without opening the sac, the mortality was 40 per cent. That showed that cutting into the sac and the wounding of the peritoneal surface was not a trifling matter.

Dr. DENHAM said that some time ago he found an aged lady, upwards of 70 years of age, suffering from strangulated hernia. He ascertained that the strangulation had taken place eight or nine days previously. The surgeon who attended her thought he had succeeded in reducing the strangulation, and attributed the symptoms which existed to some inflammation or natural obstruction. On examining the patient he was able to ascertain that a small portion of the intestine was strangulated in the groin. The room was fœtid from stercoraceous vomiting; the woman was extremely low, almost pulseless, and in a very critical condition. He had to undertake the operation himself, for the first time in his life, and probably might never be called upon to do so again, and he was happy to say he performed it successfully. In that case he was able to cut down on the stricture with comparative ease and to remove the stricture, and immediately on doing so he found the intestine slipping from under his finger. He

then returned the sac also; he was obliged, however, to still further relieve the stricture. In some hours after the operation the bowels were affected for the first time after nine days, and after a prolonged illness the lady perfectly recovered, and was now alive and well. He did not open the sac. This lady had occasionally worn a truss and occasionally went without it. The intestine used to come down sometimes, but only sufficiently to render her uncomfortable. It was decidedly strangulated for eight or nine days.

Mr. WHARTON said, in reply to the question of Dr. BANON, whether the suggestion he had thrown out applied to all cases, his opinion was that it was a desirable rule to hold by in all cases of strangulated hernia.

Mr. BANON read the following paper on a case of

REMOVAL OF LOWER JAW.

The case which I have this evening the honour to bring before the Surgical Society is one of epithelioma of the gums behind the incisor teeth and extending on each side as far as the first molar tooth. The disease had no connexion with the front gums or cheek, but appeared intimately connected with the posterior surface of the body of the lower maxilla, and formed a tumour in the floor of the mouth, seriously interfering with deglutition and respiration, from its pressure forcing the tongue backwards on the pharynx. The subject of the case was a gentleman, aged upwards of 40 years, who first called upon me in the beginning of April in the last year. He stated that about four or five months previously he first observed a growth at the back of the incisor teeth which he compared to the disease called "lampers" in the horse. At first it gave him but little uneasiness, but soon became painful to a great degree, and interfered with his articulation. It now grew more rapidly, so as to affect his power of swallowing, and occasionally produced a sense of choking. Under these circumstances he consulted his medical attendant in the south of Ireland, who recommended him to seek relief in Dublin. From the appearance of the parts and the rapidity of its growth and other symptoms, I had no doubt of the disease being of a malignant nature, and at once determined on a consultation as to whether, in the critical condition of the patient, an operation would be justifiable. Mr. Adams saw him with me on the same day, and agreed with me that, although little hope could be entertained that the disease would not return, the removal of the diseased mass, together with the portion of bone to which it was attached, was called for under the circumstances. He had, however, been latterly living so intemperately that he was advised to return to the country for two or three weeks and relinquish his habits of intemperance, with the understanding that something would be attempted on his return. Accordingly, he again called upon me at the end of the month, having followed our advice. His general health was improved, but even in that short period the disease had made sensible progress. The pain and other symptoms had become, if anything, aggravated, so that I now determined that no further time should be lost. I was unable again to avail myself of the valuable assistance of Mr. Adams, whose serious illness just then commenced. I had, however, the advice and assistance of my friends, Mr. Porter and Dr. Seward, who both recommended an immediate operation, which was performed on the 26th of April, 1865. The patient was placed in a strong chair and chloroform administered, it being determined that the first steps of the operation should be performed under its influence. It did not, however, act as well as we could wish. The first molar tooth on the left side being previously removed, the corresponding one on the opposite side being long absent, a small incision was made on the right side underneath the jaw corresponding to this point with a narrow bistoury carried from below upwards, behind, and close to the bone into the mouth. A narrow metacarpal saw was now introduced into the opening from below and passed through the mouth, the lips being held

aside by Mr. Porter. The bone was sawn through from behind forwards, but rather slowly. A similar incision being now made at the opposite side, the chain saw was introduced from below and through the mouth, and was found much more manageable and rapid in its action than the metacarpal saw. The bone being now completely divided on each side, the next step was to unite both incisions by a transverse one in front, passing down to the bone, from which the soft parts were dissected. Mr. Porter now caught the bone with a strong forceps whilst I separated the tumour, with attached bone, from its deep attachments in the floor of the mouth underneath the tongue. Before dividing, however, the muscles in this region Mr. Porter held forward the tongue by means of a ligature passed through it, so that all risk of suffocation from its falling back was averted. Until now the hæmorrhage was but slight, the incisions being made in front of the facial arteries, a few small arteries only requiring torsion, but deep under the tongue in the cavity left by the removal of the tumour smart arterial hæmorrhage took place, which was most satisfactorily arrested by acupressure. The external wound was now brought together and secured with several points of silver suture, the cavity being plugged with lint. His progress was most favourable, the wound having healed in a fortnight, mostly by the first intention, and leaving scarcely any deformity. The acupressure needle was removed on the third day, no hæmorrhage following.

For several months this gentleman went on without any bad symptoms, his articulation alone remaining somewhat defective, principally from the tendency of the remaining portions of the maxilla to converge or fall in towards each other, thus pressing the tongue backwards. When I last saw him, however, there was some suspicious thickening underneath the tongue, which, I fear, may be the commencement of the disease, no trace of which could be observed for at least eight months after the operation. My friend, Dr. Barker, who examined a portion of the tumour, says, "the diseased part seems to have been confined to a matrix of curled fibrous tissue, and consists of a few nucleated bipolar cells of large size, and a large quantity of germinal matter. I consider the disease was of that character that does not engage the glandular system, and not likely to return." Dr. Barker is so far right that at no period did the glandular system appear to be engaged, but I much fear, from my last examination some weeks since, that indications of a return of the disease are already present. It is for the Society to decide the exact nature of the disease, which I now exhibit. My own impression is, that it partakes more of the epithelial form of cancer, commencing in the soft parts and extending to the bone than of any other.

Mr. PORTER said that in consequence of the intemperate habits of the man, it was almost impossible to get him under the influence of chloroform. That was the reason they tried to saw the bones, by the two button-holes, as it was termed. Mr. BANON had seen the lower maxilla cut with a metacarpal saw, with Butcher's saw, and with a chain saw, and he believed the chain saw to be the best of all. In this case he (Mr. BANON) passed in the needle with the saw with the greatest facility, and he believed he cut through the bone in a less time than it could be done by the metacarpal saw or Hays' saw. The vessels under the tongue were commanded by Simpson's third mode of acupressure, and nothing could be more satisfactory.

Mr. COLLIS—Where were the needles applied?

Mr. PORTER—Through the mouth.

Mr. WHARTON asked was there any communication between the extremities of the bone on each side, and how the space was filled up.

Mr. BANON said that in a short time afterwards the space left was a hard cartilaginous surface, perfectly free from any appearance of disease. The two edges of bone had converged to a certain extent, the small opening between them being filled with this cartilaginous matter, and it extended in front, so as to form a new chin.

Mr. L'ESTRANGE asked had they ever seen his forceps cutting down the lower jaw in one cut.

Mr. PORTER said he recollected Mr. Cusack using it, and performing the operation with the greatest possible ease.

Mr. FLEMING said he had also used it.

Mr. STAPLETON referred to the difficulty of cutting with the chain saw in consequence of its becoming locked. If the locking were prevented the operation could be rapidly effected. There was a certain way of cutting with a bone forceps. If great pressure were used it would not cut.

EXCISION OF KNEE-JOINT.

Dr. EDWARD HAMILTON said—I think it may not be uninteresting to lay before the Society the portions of bone removed in an operation of excision of the knee performed on last Saturday at Stevens' Hospital. A man, about 30 years of age, who had served in the army in India, several years ago received an injury by the kick of a horse at the inner side of the right knee-joint. He was for some time unable to use the limb, but subsequently returned to his duty; the joint again became weak and painful, which ultimately led to his discharge about two years previous to his admission. In last October he received a second injury from a fall, whereby the joint became very painful and useless. On examination, the limb was wasted; the joint not much enlarged, but very movable, especially in the lateral direction, this caused most intense pain; the patella was found to grate when moved; many attempts were made to obtain a stiff joint. He was now again placed in a fixed apparatus with that object, and retained until month after month passing over no improvement was manifested. The question of operation then came to be decided, the man himself being after some time most anxious for it. Although I am not favourably impressed with the operation of excision of the knee-joint, yet the case seemed so suitable for it, that, in consultation with my colleague, that proceeding was determined on. There were no peculiarities in the operation, the **H**-incision being adopted; the inner one was not made as far back as usually directed, to make sure of avoiding the saphena vein, a wound of which I consider a great disadvantage in the operation; the external one was kept well back and the bones divided from behind forwards. One small point on the tibia required the use of the gouge. The bones present the following appearances: the surface of the patella was denuded of incrusting cartilage; some small spots of which were seen remaining on the femur and tibia; a scale of bone was just detached from the surface of the tibia, but there was no trace of suppuration in or about the joint, although the ligamentous structures were completely removed.

THE PRESIDENT'S ADDRESS.

The CHAIRMAN then said—In closing the thirty-fifth session of the Surgical Society, it affords me great pleasure to be able to congratulate you on the success which has attended our meetings. I am sure you will all bear me out in the statement, that our labours during the past session have been as productive of instruction as most preceding sessions could boast of. No doubt the interchange of knowledge has borne the usual fruit and the sifting of individual opinion, the result of the well-directed and well-sustained discussion which, in most instances, took place cannot have failed to ripen previously acquired information. Perhaps the session has been characterised more by the number of recent specimens exhibited than by the number of papers read. However, of this I am confident, that every one who has attended the meetings regularly, having listened to, or taken part in, the discussions, with a mind couched and free from bias, without preconceived notions deeply rooted, will admit either that he has reaped fresh knowledge, or fertilized the field of his previous knowledge (hear). Remember that to learn the truth, to unlearn error, to improve our conception of the truths we have reached, constitute the worthy end of

every project for the advancement of instruction. It would be unpardonable to occupy your time with anything bordering on an analysis or even a summary of the several subjects, which have been introduced and discussed during the session now ended. Such passing notice is the less called for, since the design for some time in contemplation will, I trust, be soon carried out, and that you will have in your hands a report of the proceedings of the Society printed in a connected form. It has been said, and with some truth, that owing to the discrepency of opinion expressed, one is apt to leave this room after an animated debate in a degree of perplexity, and undoubtedly it is very difficult to reconcile conflicting opinions from the impression exerted on the mind merely by memory. But where the whole subject is spread out in print before the eye, and you can go leisurely step by step through every argument, and trace link by link the chain of evidence in favour of one view or another, of one argument or another, you can draw your conclusions, as the legal judge does, from the weight of each and from the sum of the proofs (hear). I have now only to thank you for the courtesy you have extended to me on every occasion that I have had the honour to preside here, and to wish prosperity to our Society. I trust that the Surgical Society of Ireland, ere it has added a very few years more to its age, will have so grown in strength and proportions, as not merely to rival, but to eclipse the sister societies in other countries, and thus help to uphold the national fame of the institution that gave it birth (applause).

The proceedings then terminated.

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS, IRELAND.

18TH APRIL, 1866.

SEVENTH MEETING.—SESSION 1865-66.

Dr. BEATTY, President of the College, in the Chair.

THE minutes of last meeting were read and confirmed, after which Dr. MACSWINEY read a paper, entitled

NOTES OF A CASE OF RECOVERY FROM TRAUMATIC (?) TETANUS.

The patient, a lad aged 10, presented unmistakable signs of opisthotonos; and Dr. MacSwiney remarked that his (the patient's) eyes afforded a typical example of what the late Mr. Colles, in his description of the "tetanic face," was in the habit of calling "the peering eyes of tetanus." It was further remarked in this case that there was no appearance of a cut or abrasion of any kind; but Dr. MacSwiney detailed two occurrences, either or both of which he thought may have exercised an important influence in producing the attack. One of these occurrences was his having slipped down stairs and hurt his back about a fortnight before the supervention of tetanic symptoms; the other—which happened at the same time—was his having unsuccessfully attempted to carry an older boy than himself on his back. After desisting from this attempt, he was noticed to be pale and exhausted, and Dr. MacSwiney entertained no doubt of the spinal cord having received some hurt from that cause. Dr. Banon was called into consultation, confirmed Dr. MacSwiney's diagnosis, and both agreed that but faint hope of recovery could be entertained. Notwithstanding this opinion, however, the patient was pronounced to be quite well on the nineteenth day after the attack.

The object of the treatment adopted was to allay or mitigate the violence of the convulsions by the application of counter-stimulation along the course of the spinal column, and the administration of some of those substances known in medicine as antispasmodics; also, to sustain the energy of the muscular system by the frequent and persevering exhibition of invigorating and nutritious substances. Besides a good allowance of animal food, in the shape of eggs and beef-tea, the patient took from six

to twelve ounces of wine in the twenty-four hours, in half-ounce doses.

The drugs employed were sulphate of quina (for enemata); also, internally, chloroform, the tinctures of belladonna, Indian hemp, opium, hyosciamus, and Hoffman's anodyne liquor. Vesicating collodion was employed along the spine.

Dr. QUINLAN described a case of

FISSURE OF THE STERNUM

in a patient in St. Vincent's Hospital. This fissure was the result of caries of that bone, and, though much smaller, resembled the celebrated congenital case of M. Grønn, exhibited in Dublin in the year 1857. The fissure was filled up with thin cicatrised skin, under which could be distinguished three separate undulations, movements which Dr. Quinlan referred to the right auricle, the right ventricle, and the commencement of the pulmonary artery. On applying the stethoscope, the ordinary sounds of the heart were heard much louder than usual, and at the end of the first sound a slight peculiar metallic sound was occasionally audible. When the patient spoke continuously or coughed, the left lung protruded so as to fill up the depression in the opening. Dr. Quinlan called attention to the great force of the action of the right auricle, and detailed a series of observations which he had made as to the exact difference of time between the ventricular systole and the pulse, on the dorsum of the foot, the wrist, and the neck.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Dr. MOIR, President, in the Chair.

The eighth meeting of the forty-sixth session of the Medico-Chirurgical Society was held in their hall, 117, George-street, on Wednesday, 2nd May, at eight o'clock p.m.

Dr. SANDERS exhibited a drawing of the

BASE OF THE BRAIN OF A WOMAN, THE SUBJECT OF APHASIA.

He pointed out that though the patch of softening did implicate Broca's convolution to a small extent, yet that it was chiefly confined to the island of Reil, and from this being so much more central a part of the brain than Broca's convolution, he was disposed to consider it more likely to be the seat of so important a function as that of speech, supposing that faculty to be connected with only one limited part of the brain, which had not yet been proved.

Dr. WARBURTON BEGBIE read a long and elaborate paper upon

PARACENTESIS THORACIS IN THE TREATMENT OF PLEURAL EFFUSIONS, ACUTE AND CHRONIC.

In this paper he strongly advocated the employment of paracentesis as an important means of treatment, not only in chronic but even in cases of acute pleuritic effusion. The paper was copiously illustrated with numerous cases, and notwithstanding its length, was listened to with marked attention.

The President, Dr. Haldane, and Dr. Halliday Douglas made a few remarks upon the subject, after which the Society adjourned for private business.

OCCURRENCE OF ERGOT ON DIFFERENT PLANTS.---

Dr. Kühn has observed the ergot to occur on twenty-eight graminaceous and five cyperaceous plants growing in different positions and on soils of opposite qualities. He comes to the conclusion that moist bad soil and low position have little to do with its development. The fungus (*Claviceps purpurea*, Tulasne) produces in from twenty to thirty capitula upwards of a million spores, which readily germinate. He reared the ergot from spores placed in flower pots.—*Year-Book of Pharmacy.*

Hospital Reports.

[THE reports in our present number comprise Dr. Lyons's views on "Typhus Gravior;" Eruptions in Typhus; and an Illustrative Case of Typhoid Fever; also a case of "Hysterical Wry-Neck," and a somewhat rare case of "Poisoning by Oxalic Acid," under the care of Mr. Hamilton. Further, a case of "Anthrax," treated by Dr. O'Ferrall, according to his usual method. Other reports are in type; but are deferred to next publication.—T. W. B.]

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

DR. LYONS'S CLINIQUE.

THE Fever Clinique of this great Institution presents to the student and junior practitioner the most ample field of observation and research.

Typhus.—The type of fever prevailing for some months past has presented numerous well-marked examples of the "typhus gravior," with extreme asthenia, failure of the circulation, and a considerable proportion of deaths, in many instances attributable to thoracic complications. Interspersed with these cases, which realize some of the gravest phenomena of the fever of the famine years, are to be found instances of maculated typhus, in which, after the first week, defervescence commenced to be accomplished without distinct crisis, and patients, both male and female, who, from the severity of the symptoms at the outset, threatened a hard struggle for life, passed almost prematurely into convalescence. In numerous instances lowering of the pulse was observed days before the pyrexial action, as indicated by the thermometer, had fully subsided. In certain cases, the pulse went down considerably below the standard of health, ranging at the fifteenth or sixteenth day as low as 48 per minute.

Eruptions in Typhus.—In regard to the eruptions in typhus, Dr. Lyons forcibly observes on the want of accordance which unfortunately yet prevails amongst writers and practitioners as to the descriptions and nomenclature employed to define and designate the various spots which appear on the surface in the course of this fever. Dr. Lyons teaches that the spots proper to typhus, however they vary in size, colour, or abundance in different cases, and at different parts in the same case, agree in this, that being the result of minute congeries of vessels forced to the surface, they disappear upon pressure and reappear when the pressure is removed. The colour of the individual spot varies from the dusky, livid, bluish-brown tint of the typhus gravior to the more pinkish or "measly" rash of the lighter forms of the disease in proportion to the general carbonization of the blood, just as the colour of the intervening integument is found to vary owing to the same condition.

In marked contrast with this form of eruption, to which it is proper that the term "macula" should be strictly limited, is the permanent brownish spot or stain, the result of a minute cutaneous hæmorrhage, and to which alone the term "petechia" should be applied. The "petechia," using the term in this restricted sense, will be found to be a spot variable in size, not sensible above the level of the skin, consequently undiscoverable by the sense of touch alone, of irregular shape, dark brown in colour, unaffected in any degree by pressure, and if an opportunity be taken to examine the spot post-mortem, it will be found on microscopic examination to consist of a minute cutaneous hæmorrhage. It constitutes, in fact, a spot of minute hæmorrhagic effusion. Dr. Lyons's explanation of the occurrence of these spots is, that the condition of hæmorrhagic lesion is, under these circumstances, superadded to that of the true typhus spot, and the "ma-

cula" is thus converted into a "petechia," but it is to be understood that the macula may and does remain purely such throughout in many cases of even grave character.

That the eruption of spots of purple colour which do not disappear on pressure is only an incidental occurrence in typhus, is a fact familiar to all practitioners. In certain epidemics, and at certain periods, the presence of purple spots and purple patches of more considerable dimensions, one quarter inch to one inch and upwards in diameter, will be found to complicate the appearances offered by the skin in typhus. These spots, Dr. Lyons observes, whether large or small, will be found developed from the earliest period of the fever, associated with, and mixed up with, the proper spots of typhus, which, as can be easily demonstrated, disappear upon pressure, to reappear the moment such pressure is removed. The coincidence of both varieties of spots, and the presence of both concurrently in the same portions of the surface, proves, Dr. Lyons affirms, that the one class of spots is not caused by, or dependent in any manner upon, the other. Besides, it will be found, he states, that, if closely observed, the true spots of typhus, as long as they present no hæmorrhagic lesion, have the invariable characteristic of disappearing upon pressure.

Dr. Lyons lays great, but we think not unnecessary, stress upon the necessity of some common understanding being arrived at amongst the writers on, and teachers of, fever, as to the nature and specific designation of the cutaneous appearances presented in typhus, and he proposes that the term "macula" should be limited to the true spot of typhus, all but invariably present at some period in the typhus of this country, appearing at a tolerably fixed period of the disease, between the fifth and eighth day, disappearing on pressure, to reappear immediately when such pressure is removed, and generally continuous to about the tenth or fourteenth day of the fever. Should, however, minute hæmorrhagic lesion take place in the site of the macula, it becomes converted into a spot not removable by pressure, and is then to be designated a "petechia." To the spots of distinctly purple colour, level with the skin surface, undistinguishable by touch alone, permanent and unaffected by pressure, he applies the term "purpuric." This spot is only occasionally present in the true typhus, and, when present, is due to the associated condition of purpura hæmorrhagica. It ultimately disappears by absorption of the effused hæmatin, fading of colour, and transition through all the tints, from purple to yellow, characteristic of what takes place in the gradual removal of all cutaneous blood stains. The presence of the "purpuric spot" is undoubtedly an important complication of the typhus state, and is so far regarded by Dr. Lyons as evidence of the additional gravity of the case. To those practitioners whose experience runs back to the epidemics of the famine years, the presence of the larger patches of purpura, with further proof the association of the hæmorrhagic condition, by bleedings from the nose, gums, &c., will be no unfamiliar occurrence, as stated by Dr. Lyons.

Typhoid Fever.—Frequent examples of this form of fever are to be met with intermixed with the cases of true typhus, and sometimes with symptoms and under circumstances requiring no little care and attention to establish a diagnosis.

That a close resemblance exists in certain cases between the outward appearances in typhus proper and true typhoid fever, Dr. Lyons affirms, cannot be doubted by those who have had a sufficiently extensive experience of the two diseases. That they were long confounded is no little evidence of the similarity of the phenomena often presented by both when viewed superficially, though it is undoubtedly true that in numerous cases of typhoid there is a total absence of the dusky hue of skin, prostration of the system, and depression of vital energy so early developed in typhus, and which constitute such marked features in that disease.

In numerous instances, however, both at home and abroad, Dr. Lyons states that he has seen examples of true typhoid and also of cholera typhoid, in which the prostration of the

system, "the facies typhosa," and the general dusky tint, of skin, produced a striking resemblance in external appearance to the features of the Irish typhus proper. Nothing can be more different in symptomatological characters, he freely admits, than typhus and typhoid as ordinarily presented in these countries, and no error could have been more improbable than that the one disease should have ever been confounded with the other, did the symptoms in each invariably correspond to a type of diseased action so distinct in the one case from what is ordinarily presented in the other. From the clear skin, slightly flushed face, smart pyrexia, and absence of all depression of system, which characterize not a few cases of typhoid at the outset, as witnessed in these countries, the more common error is, in Dr. Lyons' experience, that the affection is confounded with the milder forms of non-eruptive or simple continued fever. This is especially so in those insidious cases in which the intestinal lesion does not progress *pari passu* with the fever, but remains latent, there being little or no diarrhœa, and after a false convalescence of it may be weeks, a month, or more, is again brought into dangerous and often fatal activity by want of caution in diet, premature exposure, and return to ordinary avocations, and the habits and usages of health.

Dr. Lyons then teaches that while in ordinary instances typhus and typhoid are as widely different in appearance and general symptomatology as they are in the pathological conditions which essentially characterize them, cases will frequently be met with, both at home and abroad, in which typhoid presents many of the outward phenomena of typhus, and in this superficial resemblance is to be found the true source of the confusion which so long reigned as to the nature of these important maladies.

He further enforces the necessity of practically recognizing the distinction in typhoid between those cases in which the intestinal lesion progresses *pari passu* with the fever, and those more insidious forms of the malady in which the deposit of typhoid matter in the patches of Peyer and the solitary glands remains in a quiescent condition for a period more or less considerable after the subsidence of the primary pyrexia.

In this latter class of cases, Dr. Lyons observes, the true nature of the disease is often overlooked at the outset; the patient convalesces, but imperfectly, and after a week, a month, or longer interval, new pyrexial action is lit up in the system. In this manner more than one relapse has been known to occur, and as has happened in well-marked instances in Dr. Lyons's experience, death has ensued from intestinal ulceration with protracted diarrhœa, or, it may be, profuse hæmorrhage from the bowels, at an interval of fully three months from the commencement of the primary attack of fever.

Typhoid fever; frequent relapse; melæna; phlegmasia alba; recovery.—The following case may be noticed as an example of protracted typhoid with a somewhat unusual complication. The patient presented well-marked typhoid fever, with unequivocal symptoms of intestinal lesion, and on two or three occasions had profuse melæna. Under appropriate treatment, and a diet rigidly limited to the blandest farinaceous aliment, with milk and eggs, he slowly convalesced, but not without repeated renewals of the pyrexial condition and a hard struggle for life. When convalescence had apparently fairly set in, a new feature was superadded to the case which further threatened existence. With little or no distinct premonitory symptoms, smart pyrexia again supervened, and the right lower extremity was found to swell up rapidly, and on the second day was enlarged from groin to ankle, and through the whole foot, to at least three times its ordinary dimensions. Some slight pain was complained of in the groin, and along the line of the saphena vein; pain was also elicited on pressure along the course of the iliac artery and vein, and shortly after much venous marbling was noticed on the upper and outer part of the thigh, and lower and right side of the abdomen and flank. The pulsation of the femoral artery was extremely feeble, and on one day

hardly perceptible. The temperature of the affected limb was sensibly higher than that of the opposite one. Perfect rest, leeches over the site of most pain on pressure, wrapping the whole limb in cotton wadding, with wine and tonics (the phosphates of strychnia, iron, and quinine), were attended with the happiest results, and after a period of three weeks the limb was gradually restored to its normal condition. The total duration of this case was over seventy days. Dr. Lyons illustrated his observations on this case by reference to another which he had recently seen in private, occurring in a young chlorotic unmarried female, independently of any true febrile state, and in which the disease occurred in each lower extremity successively, being attended, however, with far more distress and suffering, and requiring repeated leeching, with bold stimulation. This case likewise ended favourably, and bore iron with markedly beneficial results. In neither of these cases was albumen at any time present in the urine.

RICHMOND HOSPITAL.

(Cases under the care of Mr. HAMILTON.)

HYSTERICAL WRY-NECK.

A CASE of hysterical torticollis, under Mr. Hamilton's care, is worth notice.

The patient, a healthy-looking young girl of 19, when admitted, presented an unusual degree of deformity, the head being drawn down to the left side to such an extent that the ear nearly touched the shoulder; there was also a twist of the head, so that the face looked rather to the right side. She had formerly been in the hospital with a fixed hysterical joint, which suddenly got well. The muscles of the neck, particularly the sterno-mastoids, were very rigid, and from the head being drawn somewhat backwards, there was a deep hollow just below the occiput. Any attempt to straighten the head was attended with great pain, and was violently resisted by all the muscles. There was exquisite tenderness all down the cervical spines and a dull pain in the back of the neck.

The indications for the cure of the complaint laid down by Mr. Hamilton were—to restore the head to its natural position by manual efforts, to keep it so by mechanical appliances, and to combat the hysterical disposition to which the deformity owed its origin by appropriate internal treatment. She was put under the influence of chloroform, and the head, not without force, put straight. The next morning it had become crooked again. It was again forcibly straightened without chloroform, and with more ease than before. This was done every morning. Electro-magnetism was applied, but, curious to say, at first without her perceiving any sensation from it. A blister along the cervical spine, and valerian, ether, ammonia, and iron, administered. The most important part of the treatment perhaps was the use of an instrument for keeping the head straight after it had been forcibly rectified. It would be hard to describe this instrument in words, it is sufficient to say that it consisted of two steel bands across the shoulders with upright bars and pads, regulated by screws, so as to press on any part of the side of the head or face. The effect was so satisfactory that she left the hospital on Saturday last, April 28, with the head nearly quite straight.

CASE OF POISONING BY OXALIC ACID.

A very important case which occurred under Mr. Hamilton's care during last month is particularly worthy of record. The patient, a man aged about 40, by occupation a servant, was in the habit of cleaning shoes and boots, and for that purpose he kept a solution of oxalic acid, one ounce to a tumblerful of water.

Coming in one day thirsty, he seized the vessel just mentioned, and, under the impression that it contained water, he drank its contents. At once he perceived his mistake from the burning acrid taste in his mouth and pain

in the stomach; he vomited almost immediately, and within twenty minutes was in the Richmond Hospital, where Mr. Henry, the resident pupil, forthwith gave him a quantity of magnesia followed by an emetic.

In this case almost all the symptoms usually described in books were present, so that they need not be here recounted. There were, however, two very remarkable features in it—first, that the man recovered; and, second, the absence of bloody or dark-coloured vomiting usually accompanying poisoning by oxalic acid.

From Beck's encyclopædic work on "Medical Jurisprudence," it would appear that the cases of recovery are few as compared with the deaths, especially after so large a dose as this man is represented to have taken, and after so long a time had elapsed as twenty minutes from his taking the poison to his admission to hospital.

The account above given of the quantity of the poison and the manner of the patient's drinking it, ought perhaps to be taken *cum grano salis*; especially as Mr. Henry observed, that conflicting accounts of this part of the transaction were given by the man and by his friends. The difference between their statements, however, mainly tended to raise a doubt as to whether the case was one of accidental poisoning or of attempted suicide.

A train of very severe symptoms followed the first accident. He had evidently acute gastritis, pain, uneasiness, and tenderness in the epigastric region, a whitish loaded tongue, with bright red tip and edges, nausea and obstinate constipation. These symptoms gradually yielded to leeches, blistering, small doses of grey powder, and, as a purgative, the red infusion with sulphate of magnesia.

The vomited matter Mr. Henry described as *straw coloured*. This is not the normal appearance of the vomit in oxalic acid poisoning. By all writers the fluid is called dark coloured or sanguinolent, or greenish brown, or almost black. Beck, indeed, in the eleventh edition of his "Medical Jurisprudence" (ii., 499) says, "there are, however, exceptions to this; some have not vomited at all;" and Dr. Christison observes, "that this is most apt to happen when the poison has been taken much diluted."

Taylor also notes the rareness of colourless vomiting, remarking of the vomited matters, "in one instance reported by my friend, Dr. Geoghegan, they were colourless." Of course, when the fluid in the present case is described as *straw coloured*, it is not thereby meant to identify it with a colourless fluid; it is, however, more allied to it than to the coloured fluids ordinarily discharged from the stomach in cases of oxalic acid poisoning.

ST. VINCENT'S HOSPITAL.

Case under the care of Dr. O'FERRALL.

TREATMENT OF ANTHRAX BY PRESSURE.

W. P., ætat. 60, a shoemaker, and a resident of Dublin, was admitted to hospital on the 20th of April, 1866.

At the time of his admission he was suffering from an anthrax over the right hip, between the last rib and the crest of the ilium.

He stated that he had had this for three months. During the latter part of this time he was treated by a medical practitioner, who, a week before his application for admission to hospital, burned it with what, from the patient's description, appears to have been *potassa fusa*. When admitted, there was considerable swelling of the affected part, all round which the neighbouring surface was very hard and of a dark red colour.

This case was treated on Dr. O'Ferrall's well-known plan of "pressure," and when I saw it on the 25th ult., the pressure had so far succeeded as to leave nothing to be seen but a large and not unhealthy ulcer.

In the year 1858, Dr. O'Ferrall published, in the fifth volume of the second series of the *Dublin Hospital Gazette*, a memoir "On the Treatment of Anthrax by Pressure," and in a clinical lecture by the same gentleman, published

in THE MEDICAL PRESS of March 9, 1864, I find it stated that in St. Vincent's Hospital since 1858 "no anthrax has been treated by incisions, but in every case pressure alone has been employed."

This practice was noticed in France, where, in the *Journal Pratique de Médecine et Chirurgie* for August, 1860 (No. 5882), its introduction into St. Vincent's Hospital was duly recorded. It has also been recently discussed in the Academy of Medicine of Paris (*Gaz. Heb.*) At first Dr. O'Ferrall tried pressure in cases where the ordinary plan of incision had clearly failed, and he was subsequently induced to lay aside the cutting instrument altogether from the success attending treatment by pressure. The objections entertained by this gentleman to incision may be thus shortly summarized:—1, incision was painful; 2, as such it was calculated to give a shock to the system at a time when it was least desirable to do so; 3, it was accompanied by unavoidable hæmorrhage, and, in some cases, by syncope; 4, incisions were not always either efficient or final; 5, erysipelas has sometimes supervened.

Reflecting on the pathological conditions of anthrax, and the principal elements of that disease—such as gangrenous cellulitis, with engorgement and destruction of the surrounding capillary vessels—Dr. O'Ferrall considered that the difficulty was purely local, and that some local remedy might be best employed to meet it. When he pressed the diseased part with his finger, he found the dusky redness to disappear for the time; and it then occurred to him that compression, if steadily maintained, might accomplish what position was unable to effect.

The principle adopted was to maintain and promote the capillary circulation. It was necessary that the compression should be firm, and should in all cases begin at the periphery of the swelling, and gradually approach its centre.

Dr. O'Ferrall advises the dressing to be removed daily, and remarked that pus invariably oozes freely from the centre during the process, and the slough begins and continues to project until it comes away altogether.

In some localities, when the tumour was of small size, and traction of the skin not easily accomplished, Dr. O'Ferrall has found a coating of well-made collodion to be of considerable service, chiefly because of its contractile properties.

In either case—that is, whether strapping or collodion be employed, the centre or apex of the anthrax is never included in the compression, and is always left free for the discharge of pus and sloughing areolar tissue.

NARROWING OF THE PELVIS, WITH CONSECUTIVE PUTRESCENCE OF THE FUNDUS UTERI.

By Dr. SCHARLAU.

THE following case illustrates the practice in Germany in difficult labours, and gives an instance of acute gangrene, or, as it has been called by Rokitansky and Klob, putrescence of the uterus. A primipara, aged 34, fell in labour on the 3rd September, 1865. On the 5th the os uteri was fully dilated, and the forceps was applied. The "strongest tractions" were used in vain. Then a colleague assisted during two hours in a second application of the forceps. This failing, the patient was taken to the lying-in institution at Berlin. She was then very much exhausted; pulse, 128. A laceration of the vagina extending to the fundus was felt. The os uteri was rent in several places. The head presented. The child being alive, it was not thought justifiable to perforate. She was ordered ten grains of Dover's powder, and left to rest. After an hour and a half, the foetal heart being no longer heard, perforation was resorted to. The cephalotryptor (and other means of extracting) was rejected on account of the existing lacerations. The exhausted efforts of nature were trusted to for expulsion. Exhaustion increased, and in another six hours the head had made little progress.

The cephalotryptor was now applied; after a time it slipped, and delivery was completed with forceps. After labour her condition did not improve. The temperature rose from 38°·3' cent., on the first day, to 41°·2' on the ninth day. It maintained this elevation for three days, then fell to 38°·9'. She died on the sixteenth day. The pulse rose with the temperature. On the third day there was vomiting and great abdominal pain. On the sixth day the uterus was felt as high as the navel; a foul, sanious discharge flowed from the vagina. There had already been gangrenescence of the vulva. The post-mortem examination showed adhesions of uterus to intestines and abdominal wall. Near fundus of the uterus was an opening, with thin, discoloured edges, and corresponding to it was a small opening in the intestines where this had been bound in contact; so that there was a direct communication between the uterine cavity and the intestinal canal. In the vagina, corresponding to a necrosed point in the ramus of the pubis, was a long deep rent; the fundus of the vagina was perforated. The inner surface of the uterus was covered with a shreddy, blackish, putrescent mass. Near the fundus a portion of the muscular tissue was destroyed. No thrombi were formed. The right synchondrosis was torn open, and in the articulating surfaces was much purulent fluid. On the right ascending pubic ramus was a spot of necrosis, quite denuded of periosteum; opposite this spot was a rent in the vagina. The pelvis is described as belonging to the generally small class, compact; pubic arch, narrow. The conjugate diameter was a little under four inches, the transverse was four and a half inches. The cavity of the pelvis was also somewhat contracted.—*Monatsschr. f. Geburtsk. and Brit. and For. Med.-Chir. Review.*

AUTO-LARYNGOSCOPIC EXPERIMENTS MADE FOR THE PURPOSE OF ASCERTAINING THE MECHANISM OF DEGLUTITION.

By Dr. KRISHABEN.

M. KRISHABEN states, that in the act of deglutition the alimentary bolus passes along one of the pharyngeal channels on either side of the epiglottis, which last is raised by the elevation of the larynx; the bolus, consequently, enters the œsophagus at the moment when, by the contraction of the constrictor muscles, the pharynx is diminished in size, and is brought up against the bolus. The deglutition of liquids is effected in the same way, except that these pass pretty frequently over the epiglottis itself, which rarely occurs with solid aliments. A small quantity of fluid, when liquids are drunk, enters the larynx around the margin of the epiglottis and may even creep down to and moisten the vocal cords. In the act of gargling, the larynx is widely open, and a large quantity of fluid passes into the interior of the vocal organ.

It is easy to bear with the presence of an alimentary bolus in the respiratory tract—i.e., in the larynx, even on the vocal cords, and in the interior of the trachea. The sensibility of the trachea to the contact of foreign bodies is infinitely less than that of the larynx. The contact of hard and cold bodies with the mucous membrane of the larynx cannot be tolerated; but the contact of soft and moist bodies, of the same temperature as the body, can be sustained for several minutes without occasioning any cough or other inconvenience. For the performance of these experiments but little practice is required.—*Comptes Rendus and Brit. and For. Med.-Chir. Rev.*

DETECTION OF ALCOHOL IN SMALL QUANTITY (CARSTANJIN).—The liquid to be tested is mixed with a portion of platinum-black in a small flask, heated to 124° F., agitated well, and filtered. A few drops of liq. potassæ are added to the filtrate, which is evaporated to dryness over a water-bath. The residue is then mixed with a little arsenious acid, and submitted to heat. If alcohol is present, cacodyl is produced, recognizable by its garlic odour. It is suggested by M. Nickles, that propyllic alcohol will also yield cacodylic products by this process.—*Journ. de Pharm.*

Reviews.

THE FORMS, COMPLICATIONS, CAUSES, AND TREATMENT OF BRONCHITIS. By JAMES COPLAND, M.D., F.R.S. New Edition. Pp. 165. London: Longmans. 1866.

THE indefatigable author of the colossal "Dictionary of Practical Medicine" here presents us with a monograph on a disease, which, as he very truly observes, attacks all classes of the community, and is one of the most fertile causes of our mortality. His reason for writing it, or rather for republishing it (for it is in great measure a reprint from an article in the "Dictionary" published in 1832), is that his observation of the affection in practice has been uninterrupted for more than thirty years, and he probably concludes, and with reason, that the accumulated experience thus obtained, may be advantageously communicated to the profession. Dr. Copland, as may be supposed from his philosophical turn of mind and his extensive acquirements, does not slavishly adhere to methods of treatment which may have been successfully adopted by a previous generation but are no longer available, and we accordingly find that his opinions on bloodletting, for instance, as a remedy in acute bronchitis have undergone considerable modification since they were promulgated in 1832. But although he admits that bloodletting is not so easily borne as it was in former years, he yet considers that this measure has been of late years too indiscriminately condemned, and that there are certain conditions in which a cautious abstraction of blood may even at the present day be imperatively required. This contribution to practical medicine is written in Dr. Copland's characteristic style, and will be a welcome addition to the library of the medical practitioner.

A GUIDE TO THE PRACTICAL STUDY OF DISEASES OF THE EYE: with an Outline of their Medical and Operative Treatment. By JAMES DIXON, F.R.C.S., Surgeon to the Royal London Ophthalmic Hospital, Moorfields. Third Edition. Pp. 382. London: Churchill and Sons. 1866.

AMONG the practitioners of Ophthalmic Medicine and Surgery and the writers on that branch of science, Mr. Dixon has for many years held a conspicuous place; and in preparing this third edition for the press he has not limited himself to a mere revision of his former work, but has added some parts, rewritten others, and rearranged and corrected the rest, in accordance with his own more extended experience and the researches of other authors. Since the last edition of Mr. Dixon's "Guide" was published, great attention has been paid to those defects of the eye which are now believed to be due to errors of accommodation and refraction, and a new nomenclature has been devised to express those abnormal conditions; and Mr. Dixon has therefore commenced this new edition of his work by a brief but very clear sketch of this modern department of ophthalmology. Those who are unacquainted with the distinguishing features of Mr. Dixon's "Guide" may be informed that it is divided into eighteen chapters, and that the description of ophthalmic diseases and injuries, their pathology, diagnosis, and treatment, is prefaced by brief remarks upon the respective structures of the eye in a state of health. Mr. Dixon very liberally acknowledges the contributions of his contemporaries in the advancement of ophthalmology, and his book has the merit of being a most practical and useful treatise.

THE ALKALINE PERMANGANATES AND THEIR MEDICINAL USES. By JOHN HUNTER, late Assistant Demonstrator in Chemistry, Andersonian University, Glasgow. Pp. 48. London: Churchill and Sons. 1866.

THE use of the alkaline permanganates, both in the form of

the official preparation and in that of Condy's disinfecting fluid, has led the profession to investigate their physiological action more closely than has hitherto been done, and to devise methods for their successful application in the treatment of disease. Until the introduction of these substances as disinfectants by Mr. Condy, they were not even suspected of possessing any active properties which could make them available in any of the useful arts; but since the researches of that gentleman on the part played by ozone in natural disinfection, the use of the permanganates as *ozonizers* has been very generally admitted. Those who are not very well versed in chemistry may be reminded that permanganic acid contains a very large proportion of oxygen, with which element it very readily parts when brought in contact with bodies for which oxygen has an affinity, and as many diseases are now supposed to arise from a deficiency of oxygen in the system, the permanganates act by supplying the want in the form of ozone, which is oxygen in the nascent state. It would involve more chemical and physiological explanations than are compatible with the limits of a brief notice to describe the theoretical views on which the medical and surgical use of the permanganates is founded; but we may state that Mr. Hunter, in a very small compass, has brought together a great number of interesting facts in connexion with the history of the permanganates, and has described very lucidly the views of those who advocate their employment in medicine as therapeutical agents. Mr. Hunter has, we think, supplied a want which many must have felt who are hitherto unacquainted with the nature and properties of these curious salts.

ARCHIVES OF DENTISTRY: a Record of Dental Knowledge, Medical, Surgical, Microscopical, Chemical and Mechanical. Edited by EDWIN FREEMAN. Vol. I. London: Churchill and Sons. 1866.

THESE Archives, which it is intended to publish periodically, probably quarterly, are to contain original papers, discussions, reports on dentistry transactions, of interesting foreign papers, an abstract of the general progress of dentistry in all parts of the world, and criticisms on dental literature. In the introductory address it is stated that the Archives are designed to serve as a medium of communication between the medical and dental professions, and it is hoped that through its pages practitioners of medicine may obtain an insight into the present state of dental knowledge and be induced in return to impart to dentists the results of observation and experience on points of practice. The assistance of the younger members of the dental profession is especially invited, as it is suggested that they have had the advantage, denied to many of their elders, of systematic instruction in the dental art. The present volume contains some very valuable papers, both theoretical and practical, in reference to the physiology and pathology, and therapeutics of the teeth, and when we mention that the names of Mr. Freeman himself, Dr. Beale, Dr. Richardson, Professor Owen, and Mr. Salter, are to be found among the contributors, we have sufficiently indicated their scientific value. Among the reviews and extracted articles we find some transactions from foreign authors, and a lecture on the "Structure and Formation of the Teeth" by Dr. Lionel Beale, which originally appeared in our journal. We wish success to the Archives.

ON REFLEX PARALYSIS. By WILLIAM GALLOWAY, A.M., Ph.D., &c. &c. London: Churchill and Sons. 1865.

THE above treatise is a pamphlet of forty-eight pages, and had for its foundation a paper on the infantile disease which was read before the Dundee Medical Society by the author, a practitioner in that town. This paper has been extended, and in its present shape it includes observations on reflex paralysis, as it occurs in adults. A considerable part of the

forty-eight pages is occupied with a *résumé* of the opinions of various authorities, home and foreign; as, for example, the views of Rilliet, Bouchut, Duchesne, Romberg, Brown-Séguard, Wilks, Kennedy, Lee, West, and others; and the name, definition, predisposing and exciting causes, accession, symptoms and progress, and indications of treatment.

Dr. Galloway is of opinion that treatment "ought to be directed—1st, to the paralysis; 2nd, to the atrophy; 3rd, to the deformities." Indications of cure, he believes, will be—

"I. TO THE PARALYSIS.

"1st. To seek out and remove the irritating cause.
"2nd. To prevent or diminish the transmission of nervous influence to the spinal cord.

"3rd. To counteract the contraction of the bloodvessels of the spinal cord, by increasing the amount of blood circulating in them, and thereby increase its nutrition.

"4th. To increase reflex action, the vital property of the spinal cord.

"5th. To invigorate the constitution."

"II. TO THE ATROPHY.

"1st. To counteract the contraction of the bloodvessels of the motor nerves and paralyzed muscles, by increasing the amount of blood circulating in them, and thereby to increase their nutrition.

"2nd. To awaken the nervous energy of the motor nerves.

"3rd. To increase the muscular irritability of the paralyzed muscles."

"III. TO THE DEFORMITIES.

"1st. To prevent deformities as far as possible.

"2nd. To remedy deformities by orthopædic measures."

The last few pages are devoted to the consideration of the *position of the patient in bed; cold and heat applied to the spine; galvanism*; the use of strychnia, sulphur, phosphorus, iodide of potassium, ammonia, quina, and iron. Dr. Galloway remarks that "Dr. Joseph Bell of Edinburgh has found great benefit from the use of bitter ale in a case of diphtheritic paralysis."

We are not aware of any pamphlet on this subject which contains so much useful knowledge and so many good hints as that of Dr. Galloway's now before us. We have no hesitation in recommending it to the attention of our readers.

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 9, 1866.

CHOLERA AND ITS PREVENTION.

WE alluded last week to the fact that a fatal outbreak of cholera had occurred in a vessel sailing from Liverpool to New York, one hundred and forty deaths having occurred in little more than a fortnight, and a great number of persons having been landed in a dangerous condition at Halifax when the ship arrived at that port. We also stated that this disease broke out at sea among a number of the German or Dutch emigrants, who formed the steerage passengers, and who embarked on board the vessel at Liverpool. It has subsequently transpired that it has lately become a common practice for emigrants from Holland to America to pass through England by special arrangement with some of the railway companies, and to embark at Liverpool, this route being the cheapest. Since our article was written, a decided case of fatal cholera has occurred at Bristol, the person attacked being a sailor who had just come over from

Rotterdam to London, and who had, in all probability, brought with him the seeds of the disease.

As a further evidence that the present outbreak of cholera originated in Germany, we learn that two cases lately reported in Liverpool as occurring among the German emigrants, have terminated fatally, and it is believed that other cases have been brought under notice. It also appears that in a ship, called the *Helvetia*, sailing from Liverpool for New York, the disease has broken out among the German emigrants. Before the ship left Liverpool, two German passengers were sent ashore in consequence of showing dangerous symptoms, but when the vessel went to sea, all the passengers were apparently healthy. But she had scarcely arrived at Queenstown before the disease broke out, and two men had died when she reached the port. The Admiral in command in Ireland ordered the vessel back, and as we write, she is, we believe, returning to Liverpool.

It is satisfactory to be informed that on Thursday last the Directors of the National Steam Navigation Company in Liverpool passed a resolution to put a stop for the present to the conveyance of German and other steerage passengers between Liverpool and New York by their vessels; and we are also told that a Government prohibition has been issued against all German emigrants entering England who have not been submitted to medical examination.

The particulars which have transpired in reference to the recent outbreaks of cholera on board the ships *England* and *Helvetia*, while they are calculated in some respect to increase the obscurity in which the pathogeny of the disease is involved, offer some important suggestions as to the prophylactic treatment. In the first place, it is very difficult to reconcile the facts, as they are reported, with the theory of the *water origin*, as it may be called, of the disease. Here is a malady carried on board a ship, breaking out with great virulence at sea, and spreading from one person to another, without, as it appears, any other mode of propagation than that which naturally suggests itself—namely, the communication from diseased to healthy individuals by personal contact, or at least by proximity. On board a ship we can hardly conceive that the seeds of cholera can be conveyed by persons using contaminated drinking water, or by the introduction into that water of the discharges of those who are affected. It really appears that the zymotic theory, which has lately fallen into some disrepute, explains the facts in a far more intelligible manner; but as we possess, as yet, no detailed and scientific account of the progress of the malady, we are unwilling to offer any dogmatic opinions on the subject.

It is far more important to determine, and without any delay, what is best to be done under the present most alarming circumstances, when the disease is at our very doors, and indeed within our thresholds. The utility of quarantine, long disused in many countries, is again beginning to be canvassed, letters on the subject

are appearing in the public journals, and the topic is being discussed in the Houses of Parliament. There is no doubt that the system of quarantine has been very grossly abused in several countries, and great inconvenience has been occasioned by its operation; but, on the other hand, no one can have traced the progress of the cattle plague without being convinced that a system of isolation of the diseased animals is the only efficient preventive, and no one can dispute the proposition that if the German emigrants had been forbidden to land in England some 270 lives, which were sacrificed on board the *England* in its passage from Queenstown to Halifax, might have been saved.

In a letter which has appeared in the *Times*, Mr. HARRY LEACH, the Resident Medical Officer of the *Dreadnought* Hospital Ship, offers some very useful information on this subject, gathered by himself in a recent visit to Turkey and the Principalities. In those countries, as is well known, the system of quarantine has long prevailed, and has been wholly inefficient, but Mr. LEACH points out that the inefficiency is due to the absurd manner in which the quarantine regulations are carried out, and not to the system itself. In fact, it appears that quarantine in Turkey is a mere farce, the lazarettoes being placed in close proximity with the habitations or workshops of healthy persons; and even at Marseilles, where the authorities ought to know better, the lazaretto is close to the steam-boat pier. On the other hand, Mr. LEACH points out that in the kingdom of Greece, and in the islands adjoining the Morea, the system of quarantine is strictly enforced, and with such good results that cholera has been completely shut out from the main land and from the islands, even although it has raged in the countries all round them. The Greek islands present, indeed, very favourable spots for the enforcement of quarantine laws, and England is of course less happily situated from its geographical condition, but Mr. LEACH throws out the suggestion that the Channel Islands, Scilly, or the Isle of Man, might be made available for quarantine stations.

The danger is urgent, and extraordinary means must be devised to meet it, and the Government has already taken some vigorous measures, which are now in operation in Liverpool, and which will in all probability be extended to the other towns on the sea coast.

VILLAGE HOSPITALS IN GREAT BRITAIN.

LARGE crowded hospitals in towns, however useful they may be to the inhabitants thereof, not unfrequently act injuriously upon surgical patients brought from the free air of the country. Indeed, they do so not only by their choky, comparatively unwholesome atmosphere, but also by the mere fact of the great distances from which they, as it were, drain their patients; and the unfortunate subject of an accident in many cases loses his limb, if not his life, from the mere fact of having been jolted about in a cart for ten or fifteen miles on his way to the nearest hospital. We know well that in

regard to all surgical cases the recoveries are most numerous in a new hospital; even inferior surgical skill gets a better percentage of cures out of such an hospital than the very best can obtain in an older one, whose very walls seem tainted with the poisons of erysipelas and pyæmia. Of course the same statement may be made to a limited extent in regard to medical cases, while it is specially applicable to obstetrical ones, but it is most true and of most importance in surgical cases, because the very nature of such cases induces them to go to hospital in much larger relative numbers than the other classes of cases referred to. We can readily perceive, therefore, the vast importance it would be for the patient to have an hospital at hand to which he could be quickly carried on some improvised stretcher, and one, too, which, from its comparative insignificance and inexpensiveness, could be given up without a thought and established in some neighbouring locality, should any of these endemic poisons appear to have localized themselves in them. It is long since Sir JAMES SIMPSON recommended peripatetic hospitals, with the view of avoiding some of the evils referred to. He suggested that the buildings should be made of cast-iron, and whenever pyæmia made its appearance, that they should be taken down and re-erected elsewhere, after due and proper disinfection. It is doubtful whether this peripatetic system would meet the wants of a large town, even though it should be found to remedy the evils complained of, while in smaller towns and villages such a system would not be required, because the small hospitals required in such situations could be at once vacated if necessary, and another cottage secured. We hold, however, that in such circumstances such a procedure would but rarely be required. In the free air of the country, with patients uninjured by long carriage, perhaps with persisting hæmorrhage, and with minds cheered by the neighbourhood of their friends, and by the knowledge that it is their own doctor, who has known them from infancy, that is attending them, pyæmia would probably be unknown. But it is not only to the patient that the establishment of village hospitals would be a boon. Charity is always "twice blessed;" and this case would be no exception, for the keeping of surgical cases amongst the country practitioners by the establishment of Village Hospitals would not only benefit the poor patients, but by keeping the doctor's hand in, and familiarizing him with surgical operations, would, so to speak, keep him at school, and maintain his anatomical and surgical knowledge in a state of constant and more or less brilliant readiness, to the no small benefit of the country squires in his vicinity, some of whom sooner or later are sure to reap the reward of their own good deeds. But, indeed, such hospitals ought to be almost entirely self-supporting. The patients will readily pay board when they can, and when they can't, of course the parish is liable for them; while all the neighbours, rich and poor, will be only too willing to send a supply of wine or other luxuries—to the sick

too often necessities—as they may be required. Seven years ago the seed of this great boon was planted at Crawley, in Surrey; since then they have been established, and are in full working order, in upwards of twenty places in England, and in one in Scotland, St. Andrews, while they are in course of erection in more than three times that number of places in England; and we hope the day is not far distant when every village in Scotland ten miles from an hospital town will have its own village hospital—an invaluable boon to the poor, a blessing to the rich, and a school for the doctor.

THE THERMOMETER AS A DIAGNOSTIC AGENT.

THE use of the thermometer as an aid to the diagnosis of disease has now become pretty general, especially in our hospitals and infirmaries, and the interest shown by practitioners in this comparatively new field of clinical research is of itself sufficient to indicate the importance of the subject. It has been the custom from time immemorial for the physician to ascertain by the sense of touch the temperature of the body in all acute affections, but it is only within a comparatively recent period that this vague and unsatisfactory mode of measuring the heat of the skin has given place to the more exact observations of the thermometer. Wunderlich has long used this instrument in practice; but the profession in this country is indebted to Dr. Aitken of Netley, for the complete and interesting information he has given on the subject in his recent work on the "Practice of Medicine," which has undoubtedly been the chief means of attracting attention to this hitherto neglected but valuable diagnostic agent. By the use of a reliable thermometer we can now ascertain to the fraction of a degree the exact state of the temperature of the body in any disease, and by its daily use we may derive information of great value, not only as to the nature of the illness we are called on to treat, but also as regards its probable duration, course, and termination. So far as our own experience goes we have found it of great service in febrile diseases; and it is chiefly, we believe, in this class of ailments that the thermometer will be found useful, although in many other acute affections, such as pneumonia, it likewise affords considerable assistance. Every medical man knows the difficulty of making a decided and satisfactory diagnosis in the early stage of fever, and often no opinion can be given with safety until the disease has taken a firm hold of the system. In such cases, then, the state of the temperature of the body, as ascertained by the thermometer, will generally remove all doubt and enable us to tell with precision the nature of the illness. There may be, for example, a quick pulse, a foul tongue, a suffused eye, rigors, vomitings, headache, and dull aching pains all over, without any persistent elevation of the temperature, and we can, therefore, safely conclude that this disturbance of the system is due, not to the presence of fever poison in the blood, but to some other perhaps less serious cause. Then, again, we may have a patient whose tongue is moist and clean, who has no giddiness nor headache, no vomitings or rigors, who in fact has almost none of the usual symptoms which herald the approach of a febrile attack, but in whom there is a considerable rise in temperature—a rise that continues to

increase till the appearance of a rash, or the manifestation of some other distinctive signs shows clearly the presence of fever. Whenever a person who has been exposed in any way to the infection of fever complains of a little feebleness, or feels out of sorts, we may feel sure if the thermometer reveals a range of temperature higher than the normal standard, that the case will result in fever, even although there may be no other indications of the presence of the poison. We had quite recently an illustration of the aid that may be derived from thermometry in doubtful cases. A girl of some thirteen years of age was received into a house where there was a large number of young people. She complained of her throat, which was swollen and inflamed, her head was sore, and she said that the day before she had shivered several times. The pulse was quick, the face flushed, the skin felt hot and dry, and there was also a suspicious blush of redness on the arms. She never had suffered from scarlatina, and all these symptoms naturally created considerable anxiety and alarm lest this fever should break out in the house. It was of the utmost importance that a decided opinion should at once be given as to the nature of the case, and whether the patient ought to be removed or not. The thermometer was applied, but the mercury did not rise above 98° , and we were thus enabled to give it as our opinion that the patient was not suffering from fever—an opinion the correctness of which was confirmed by the further progress of the case.

In a series of observations made upon typhus cases we found that in the majority of patients, the turn, as it is called, was indicated by a fall in the temperature, before any amelioration in the condition of the patient could be detected, either from the state of the pulse or the expression of the countenance; and in cases which, after the crisis had taken place, appeared to be getting worse instead of better, we found that if the temperature kept down, everything went on well in spite of a temporary rise in the pulse or other untoward sign. The observations we have yet made in other forms of disease are neither so numerous nor extensive as to enable us to speak with certainty as to their results. But we may just say that in phthisis we think that the assistance to be derived from continuous thermometric observation is not so great as some writers would lead us to suppose. It has been said that in this affection the constant and persistent elevation of the temperature is sufficient of itself, even when the physical signs are uncertain, to indicate the presence and sure progress of the disease. Now, curiously enough, we have met with at least four cases in which there were the most unmistakable evidence of the presence of tubercle in the lungs, cases in which the disease made rapid progress, and yet in each of them there was no elevation of the temperature either by night or by day. In two of them, indeed, the heat was under the usual average standard. But the thermometry of disease may be said to be yet in its infancy, and while we would caution observers to eschew everything that savours of dogmatism, and to guard against imperfect or hasty conclusions, we would, at the same time, bid them prosecute their inquiries with increasing zeal; for we are convinced that the application of the thermometer to the detection of disease will ultimately result in good, and in it practitioners will find an agent which, in doubtful cases, will yield them information which nothing else can give—information that may frequently relieve from anxiety and prevent mistake.

OUR SANITARY STATE AND PROSPECTS. (DUBLIN.)

EVERY day adds to our knowledge, as well as to our responsibility, inasmuch as the former leaves us without excuse if we do not fully discharge the latter. A very striking instance of this is seen in the result of the Cholera Conference at Constantinople. The members of that meeting, selected from different countries, professing various creeds, possessed of most extensive and most varied acquirements in medical, topographical, and ethnological knowledge, have arrived at certain decisions as to the origin, mode of propagation, and of prevention of cholera; and it now remains to be seen whether the requisite means and courage are possessed by the ruling powers who are called upon to carry out the necessary measures of observation and prevention recommended by the Conference.

We must not expect too much from the Sultan or the Viceroy of Egypt when we reflect on the amount of passiveness exhibited nearer home in somewhat similar circumstances. In Paris it was not thought advisable to institute a system of house-to-house visitation, such as had been carried out with so much benefit in England and in some places in Ireland, as, for instance, at Finglas, during the epidemic of 1854, inasmuch as it was feared that such a measure would cause a panic amongst our French neighbours. For like reasons the statistics of the disease were for a long time kept from the public eye in that most fashionable of capitals. We must not, however, consider ourselves as free from censure in many points connected with this and other matters of vital importance. If we regard the cattle plague, surely in England we have nothing to boast of, either in the way of promptness and punctuality, in supplying the necessary returns or in respect to unanimity and promptitude, and a true sense of what should have been adopted from the very commencement as the best and really most economical mode of dealing with that which has cost the country so very large a sum.

Again, in Ireland, though prompt measures were most happily adopted by common consent against the importation of the cattle plague, and thus far with most excellent results; still other evils have been inflicted on us and we cannot say that we have been setting our house in order against the possible advent of cholera. On the contrary, an association has actually been formed by those rate-payers who own many of the lodging-houses tenanted by the working classes to protect themselves from the efforts of the Corporation to compel them to keep the tenements of the poorer classes in suitable habitable order. We are happy to say that the Medical Officers of the several districts of the city of Dublin have come forward with their testimony to show the great need of prompt and efficient action, on the part of the authorities, in enforcing the measures which the latter have had in contemplation; and we trust, for the sake of the labouring classes, that a comprehensive system of ready legislation will be shortly carried through Parliament to compel all holders of tenements to keep the same in proper habitable order. While, however, we record our approval of the willingness shown by the Government, the Corporation, and the Medical Officers of the several city districts, we cannot acquit the Corporation of some matters urgently requiring amendment; one is the continuance in some of the most thickly inhabited parts of town of large depôts of street sweepings. We have in previous numbers of *THE MEDICAL PRESS*

AND *CIRCULAR* shown that fatal fever arises in close proximity to these offensive depôts. We have also pointed out that cholera first appeared in 1854 in tenements adjoining one of these Corporation depôts, and that it carried off several of the people in the neighbourhood, and spread from it as a centre to other parts of the city. We can also prove that fever habitually exists in dwellings adjoining these depôts, and that each season it commences in such positions, and radiating thence, annually spreads through town. Surely such a state of things should not be suffered to continue. Ireland possesses hundreds of thousands of acres in want of the very matters which are at present allowed to accumulate, to the injury of our citizens, in Dublin. With such excellent roads as we possess; with two canals, that encircle our city, on which iron barges could be procured to convey away the town sweepings; and with numerous lines of railways in communication with (as well as the canals) very many rural, peat, mountain, and seaside districts—the state of things of which we complain ought not to exist. We commend these matters to the consideration of the members of our Municipal Council as eminently within their province.

And while we ask the attention of the authorities to such commonplace but eminently useful matters, we would solicit their attention to the state of the cowsheds and yards of Dublin, and to that of the parts of the city and its vicinity where pigs are kept, but too commonly in close proximity to the apartments occupied by the owners of these animals. We have before quoted in these pages the proceedings of the civil authorities in some of the Italian towns, where cholera committed most severe ravages within the last year, and we may now repeat the statement here—namely, that the very first steps taken were to turn out great numbers of pigs that had been kept by the people, as is done in very many cases much nearer home, in the midst of the towns.

In this way we will find that while, no doubt, we ought in common with all other enlightened nations, do our utmost to inform other people of the best means of preventing or of lessening the prevalence of cholera fever, &c., we certainly should not leave it in their power to say that either from the love of gain, or from negligence, or from any other cause, we permit our own country to be little better than theirs, when we consider the relative advantages we possess in many respects.

In the last published report of the Royal Navy Medical Department there is much valuable evidence as to the importance of preventive measures during epidemics, and we cannot do better than quote what may perhaps stimulate to exertion some who are now inclined to inaction on these important matters.

In 1862 and 1863 epidemic cholera occurred at Shanghai and we will briefly allude to two classes of residents at that important Chinese port—namely, the European merchants and the Chinese who had sought refuge there. The extracts also allude to the European soldiers at that station. The British Deputy-Inspector Dr. HOME, observes, "Four marked characters distinguished the better class of the European community, who, I may observe, scarcely suffered at all during the two cholera epidemics, from their less fortunate fellow-countrymen the private soldiers, on whom the disease fell on both occasions very heavily." 1st. As a rule, they (the civilians) all live extremely well, partaking of animal food always twice and often thrice a day.

2nd. They inhabit large airy dwellings and never sleep, if at all possible to avoid it, on the ground floor.

3rd. They never expose themselves to the mid-day sun, and scarcely ever to the night air, except in covered (sedan) chairs.

4th. They bathe in their own houses every morning, and in the afternoon, either by walking, riding, drilling as volunteers, playing rackets or otherwise, they take care that the system has regular and sufficient exercise.

I confess I see but little difficulty in giving the soldier the benefit of all these advantages. If his diet is improved and I am inclined to lay much stress on this (utterly interdicting the use of salt provisions), his barracks made spacious and airy, sentry and all other out-door duty reduced to a minimum, if bath rooms and the means of amusement and recreation are provided for him, and if the European corps, stationed at Shanghai, whether Infantry or Artillery, be not kept in China beyond the regulated period of three years, I see no reason why the soldier, even at Shanghai, should not approximate at least, if he does not actually reach the high standard of health in which the civilians in comfortable circumstances enjoy."

Our valuable contemporary, the *British and Foreign Medico-Chirurgical Review*, remarks, that "If the well-conditioned Europeans at Shanghai suffered comparatively little, very different was the fate of the poor native population, as we learn from the Surgeon (Dr. Morgan) of the *Euryalus* :—

"The mortality among the unfortunate Chinese who had sought refuge in the settlement, surpasses belief, which is not to be wondered at where there were so many human beings crowded together in indifferent dwellings. I have been informed upon good authority that they died at one time at the rate of 3000 a day, and as they could only procure a burial ground that could only accommodate 1000 a day, the remaining 2000 were enclosed in boxes of deal boards loosely put together, or packed up in straw or matting, and left to rot in the sun. During the time this ship was at Shanghai there were thousands of dead bodies more or less hidden from the sight of the passer-by by some loose covering, that were in a state of decomposition and tainting the surrounding atmosphere with their deadly effluvia."

We see in the foregoing the great value of healthful dwellings and sanitary precautions brought into strong contrast with the awful consequences of neglect of these measures, as seen in the poor Chinese who were crowded together in unhealthy dwellings with bad food and clothing, and we particularly would impress on our readers that these two very different states of being were consistent in the same climate at a period of epidemic cholera. The fact that the disease at present prevails in parts of Germany, and exhibits renewed evidence of its rapid powers of locomotion, so to speak, as seen in the case of the emigrant ship *England*, mentioned a few days since in the *Saunders's News-Letter*, should stimulate the public to activity on these all-important matters.

THE Vestry of St. James's, Westminster, on the motion of Mr. Compton, have resolved, with one dissentient, to petition both Houses of Parliament that the metropolis may be included in the places named in the schedule of the Bill for the better prevention of contagious diseases at certain naval and military stations.

PROFESSOR STRUTHERS ON THE EDINBURGH ANATOMICAL SCHOOL.

ON Friday evening last, Dr. Struthers, Professor of Anatomy in the University of Aberdeen, and formerly Lecturer on that subject in the Edinburgh extra-Academical School, read a most able and interesting paper at a *conversazione* given by the President and Fellows of the Royal College of Surgeons in their Hall, Nicolson-street. The subject of the paper was "The History of the Edinburgh Anatomical School," a theme which the learned lecturer was well qualified to treat. Dr. Struthers, who for long has made anatomy the great study of his life, must have had peculiar pleasure in collecting material for his instructive essay; and we are sure that the College as well as the whole profession must feel greatly indebted to him for thus furnishing us with a historical sketch of the origin and development of a department of the metropolitan medical school which has shed so much lustre on her name.

The arrangements were the same as on the previous occasions when *conversazioni* were held, the company, which was numerous and distinguished, having been first received in the museum by the President, Dr. Dunsinane, and then repairing to the lecture-room, where Dr. Struthers read his paper. The history of the Edinburgh Anatomical School, properly so called, he said, commences in the year 1720 with the first Monro, although so early as 1505 dissection was carried on in Edinburgh. While, in the year 1720, the school which so shortly afterwards was destined to rise to such eminence, was just in its infancy, the science of anatomy had already in Italy, Holland, Belgium, and France, been prosecuted with enthusiasm and success.

Many men were connected with the establishment of the Anatomical School, such as Monteith and Elliot; but it is chiefly to the labours of the Monros that Edinburgh is indebted for the place she occupies as a school of anatomy. The attendance during the first ten years at Alexander Monro's lectures was on an average sixty-seven, and at this time is probable that that number included nearly all the medical students in the city.

After labouring for a period of thirty-eight years he raised the numbers to about 200, which was the number of pupils on the roll when he retired. He resigned in 1758 in favour of his son, Alexander Monro, (secundus) who was appointed professor at the early age of twenty-one, before he had taken his degree or even finished his studies at the University. He did not enter on his duties, however, till four years after his appointment, and during the interval he devoted himself to the study of anatomy in Leyden, under Albinus; in Berlin, under Michel; in London, under William Hunter; as also in Paris. His career was a brilliant one, and the attendance on his lectures rose from 200 to 400. After lecturing for about half a century, he was succeeded by his son, Alexander Monro (tertius), who discharged the duties of the chair till 1846. The three Monros, therefore, occupied the position of Professors of Anatomy for the lengthened period of 125 years. This distinguished trio was succeeded by the brothers Bell, John and Charles, the former having lectured for fourteen years—viz., till 1800, and although the latter portion of his lifetime was chiefly devoted to surgery, he was, nevertheless, a distinguished anatomist. He was undoubtedly the father of the Edinburgh School of Surgery, and his fame as an operator was

widely spread. He is buried in Rome, and over his grave is placed a plain tombstone, on which is carved the modest inscription, "Here lies John Bell, surgeon, of Edinburgh, a man not uneminent in his profession."

Sir Charles Bell, who was twelve years younger than John, his brother, commenced his professional career in Edinburgh, then went to London, and returned to Edinburgh again. His writings are extensive and varied, and his reputation as an anatomist is considerable. But, besides being an anatomist, he was also a distinguished surgeon and an admirable artist. It is in physiology, however, that Charles Bell's name will go down to posterity. He was knighted in 1830 along with Brewster and Herschell, and died, in the sixty-eighth year of his age, in 1842. Professor Struthers then gave interesting biographical notices of Barclay, Gordon, Walker, Cullen, Fyfe, and Knox, and concluded by mentioning some of the characteristics of the Edinburgh Anatomical School.

The lecture seemed to give the greatest pleasure to all who listened to it, and at its close Professor Christison moved, and Professor Syme seconded, a vote of thanks to Dr. Struthers for his careful and instructive paper.

Notes on Current Topics.

THE TREATMENT OF THE SICK POOR IN ISLINGTON.

It is positively unfair that St. Pancras should lately have the monopoly of abuse from the journals, medical and lay, on account of its treatment of the sick poor, while many of the other parishes and unions are quite as deserving of censure. Our contemporary, the *Lancet*, in its Commission upon the state of the Islington Workhouse Infirmary, certainly let down that establishment far too gently, mildly censuring, indeed, the accommodation afforded for the reception and attendance on the sick, but praising all the general arrangements in the most eulogistic terms, and patting the Trustees on the back for their unanimous determination to erect a new building. We really think that in the case of Islington, the *Lancet* Commissioners have been gulled, and in a series of papers now appearing in the *Standard*, and written, it is understood, by Dr. Stallard, the liberality of the arrangements is represented in its true light. As for the erection of a new workhouse, if the *Lancet* Commissioners had known anything about the Trustees, they would be aware that the Islington Workhouse has been unequivocally condemned for *twelve years*, and that whenever its glaring defects have been represented, the parrot-story is always repeated that a new edifice is soon to be erected, although, to the best of our belief, that work is not yet even begun. As to the other "liberal" arrangements, Dr. Stallard tells us that the wretched sick out-door paupers are supplied with masses of fat, bone, skin, and gristle, instead of mutton chops, as ordered by the medical officers, and he hints, and we believe with good reason, that the latter dare not remonstrate under fear of dismissal. The "liberality" in the drug department may be estimated by the facts stated by Dr. Stallard, that cordial tinctures have been removed from the list; that bark is not allowed, and even iron was for some time prohibited, at least in the form of tincture. *En revanche*, however, a little peppermint is allowed, both in the aperient mixtures and in the astringent ones, and

Dr. Stallard expresses a wish that one of the Trustees could be treated with a few doses of "the chalk-and-water given for the relief (?) of diarrhœa," and, he adds, "we cry shame upon such a paltry economy." The *Lancet* admits that in applauding the liberality of the Trustees in the drug department, it mistook the drug bill for some thousands of out-patients for that incurred for the use of the patients in the infirmary. We repeat that our contemporary has been completely gulled at the Islington establishment, and the *Standard* has put the matter in a much clearer light. When Mr. Farnall, C.B., and Dr. Edward Smith make their Report on the Islington Workhouse, and its arrangements for the care of the sick poor, their labours may perhaps be facilitated by reference to some previous reports long ago made to the Poor-law Board and still in its possession.

EGGS AND THEIR PRETENDED SUBSTITUTES.

OUR attention has been called to the circumstance, that some compounds, popularly known as "baking powders," are advertised as possessing such an amount of nutritive property as to enable persons to substitute them for butter and eggs. This idea is altogether erroneous, as these powders consist almost entirely of carbonate of soda and tartaric acid with a small proportion of rice flour, and it is said that in order to give them the colour of eggs, they are further mixed with a little chromate of lead. Such being their composition, they contain very little nutritious matter, rice being one of the least nourishing of grains, tartaric acid and soda being not nutritious at all, and chromate of lead being actually poisonous, although the quantity of the latter material is probably too minute to be injurious. These "baking powders" may be useful enough in the preparation of pastry, supposing the chromate of lead to be omitted, for the carbonic acid evolved by the union of carbonate of soda with tartaric acid may render the pastry more light and digestible, but such powders cannot afford a saving of butter by being substituted for it, nor can "egg-powders" supply the place of eggs in puddings or other articles of food. These powders, therefore, even if they be innocuous, may be the means of deceiving the public, especially the poorer classes, if those who sell them pretend that they contain ingredients they do not possess; and in the case of children, illness may perhaps be generated, if these powders are substituted for more nutritious substances.

NEW FORM OF ADMINISTERING IRON.

OUR attention has been directed to a new form of iron medicine introduced by Messrs. Ch. Collas and Co., a pharmaceutical firm in Paris. In this preparation the iron is reduced to the metallic state, and therefore resembles the ferrum redactum of the British Pharmacopœia. As it is, of course, very susceptible to oxidation, Messrs. Collas envelope the metal in gelatine capsules which prevent this result. The idea seems to be a good one, and the iron in this form is worthy of a trial by the profession. Each capsule forms a small pill containing one grain and a half of pure iron.

INDIA.—A native has been detected mixing poison in the bread made in the Government bakery at Lucknow, and has been sentenced to transportation for twelve years.

RETROSPECT OF THE JOURNALS.

MAY 5, 1866.

THIS week's journals are rather devoid of interest.

The cholera is the favourite topic of the hour. The *Lancet* seems to think that if we were to be visited by it this year, we should have had some cases of it during the last winter. It is, however, very close to our doors, Rotterdam being in almost daily communication with the principal seaports of Great Britain. Wherever we have Germans congregated together in a small space, we may expect to find the cholera. Surgeons in charge of emigrant ships are in the habit of looking with horror on a cargo of German emigrants; the filthy habits of the lower orders are proverbial, and this, taken in conjunction with their peculiar diet, is the readiest explanation of the fact that we so very often hear of the disease breaking out on board ships, as it lately did in the *England*.

The House of Commons appears to be the best ventilated building of modern times, it is even said that the air inside is purer than that without. Dr. Percy has presented a report on the subject, the air is put in motion by means of combustion. Originally fans were used, but these have been superseded by the charcoal fires. On the night when leave was given to bring in the Reform Bill it was found that 1,500,000 cubic feet of air passed into the House during an hour. However, from some fault of the construction or from the excellence of the ventilation, considerable annoyance is caused occasionally by extraneous perfumes; even should any horse-dung happen to fall in the Common's-court, the odour will be immediately perceived in the House, so much so, that carriages were obliged by the police to remain in the Speaker's court. A person passing by with a lighted cigar impregnates the atmosphere to a ridiculous extent.

Appropos of the attack made on Chief-Justice Lefroy in the House of Commons lately, the *Lancet* wishes that something similar might have the effect of producing a change in the Examining Board at the College of Surgeons, where men beyond seventy years of age are required to put in practice an amount of mental and bodily exertion during a large portion of the year that can be only expected in men of the full vigour of adult life, and which under the present circumstances, tends to bring discredit on the College.

The members of the English Universities seem to be plagued by those who vend obscene publications; independent of the moral aspect of the trade in the abstract, a very grievous amount of mischief is effected by these rascals on the pockets, and worse still, the minds of young people.

There were three doctors in the passenger train that caused the fatal collision on the Brighton railway.—Drs. Murray, Habershon, and Bayfield; the former stopped all night, with the injured.

The Bermondsey Board of Guardians are taking into consideration the system of substituting paid and trained for pauper nurses in their infirmary.

£20,000 has been voted amongst the Civil Service estimates towards the erection of a building for the University of London. It is to be erected close to Burlington House, and will cost £65,000.

The dispute between Dr. F. Winslow and Dr. Tuke, we regret to observe, has degenerated into lamentable personalities.

Mr. M. B. Hill gives some interesting details of the process of injecting mercurial preparations hypodermically. The one which he has used is the bichloride; as might be expected, it causes some pain, but the effects are most marked, the patient generally being brought completely under the influence of the drug before one grain has been administered. This is an interesting point, as the plan has succeeded in those cases in which the patients were considered to have been proof against the medicine as administered by the mouth.

A good deal of excitement has been caused in the

neighbourhood of Newcastle by the accidental or intended poisoning of a respectable family, three of whom died.

Dr. Owen Davies relates a case in which he imagined that an attack of puerperal convulsions was to be distinctly traced to eating mussels.

From the *Medical Times and Gazette* we perceive that the St Paneras "laying out case" has turned up again. The Poor-law Board censure all concerned, including the doctor, who unfortunately had not seen the child for a couple of days.

The following case of dislocation of the lower jaw may be of use to laryngoscopists:—"The case which gave rise to these observations was that of a phthisical woman, 38 years of age, suffering from chronic ulcers of the larynx, and in whom complete dislocation forwards was twice produced at intervals of a month, while canterisation was being applied by means of the laryngoscope. It was easily reduced by pressure with the thumbs on the last lower molars, and drawing forward the ascending ramus embraced by three fingers of each hand. The accident may easily be prevented by cautioning the patient to moderate his coöperation, so as not to effect with too great energy the double movement of depressing and advancing the lower jaw. An excess of action in the external pterygoid muscle seems to be the chief agent in effecting the dislocation. With even a moderate separation of the jaws, such as is requisite for the employment of the mirror, the condyle of the jaw is already carried forwards; and the external pterygoid, then brought into action, exerts strong traction on the condyle, so that in predisposed persons, dislocation may readily take place."

In a communication on the subject of the use of the medicinal sulphites and hyposulphites in zymotic diseases, we fancy we can recognize the pen of a distinguished writer from this side of the Channel.

All the journals give a very unfavourable review of Mr. Brown's book on the Curability of certain Forms of Hysteria, &c.; the publication in question, as well as the report of the Surgical Home, which is in the hands of half of the English nobility, will not do Mr. Brown much credit among his professional brethren.

"CAUSE OF GOITRE.—M. Maumené is led from his observations and experiments to believe that the cause of goitre is the presence in drinking water of fluorides. These, he asserts, are peculiarly abundant in the water of goitrous districts. M. Maumené gave for a period of five months fluoride of potassium to a dog, at the end of which time a swelling similar to goitre appeared in the neck; the dog then made his escape, but three years afterwards was again discovered with a swelling which appeared to M. Maumené to have all the characters of goitre."

If the foregoing be correct, our practice of administering iodides and bromides in goitre smacks strongly of homœopathy.

Dr. McCraith of Smyrna, who may very reasonably be supposed to be well acquainted with cholera, suggests that the European powers should establish an international quarantine at Mecca.

Dr. D. Davies describes the case of cholera which occurred in Bristol, and was imported from Rotterdam. We should recollect that a steamer trades between Rotterdam and Dublin.

SOLUBILITY OF CAMPHOR IN WATER (MARKOE).---Storer, in his "Dictionary of Solubilities," states that water takes up three times as much camphor from its intimate mixture with carbonate of lime or magnesia, than when shaken with camphor alone (assuming it to be a fact that, in the latter case, but one part of camphor is taken by 1000 parts of water), making the limit of solubility one part of camphor to 333½ parts of water. Mr. Markoe, in experimenting upon the aqua camphoræ of the U.S.P., found the solubility to be 1 part of camphor in 240 parts of water. He thinks that the preliminary trituration of the camphor with alcohol, previous to its mixture with carbonate of magnesia, will explain the greater solubility.—*Year-Book of Pharmacy*.

Parliamentary Intelligence.

HOUSE OF LORDS.—MAY 1ST.

THE LORD CHANCELLOR moved the second reading of the Law of Capital Punishment Amendment Bill, which is based upon the report of a Royal Commission. The noble and learned lord explained that the Bill retained the punishment of death for murder; but placed the offence in two classes—namely, murder in the first degree, punishable with death, and murder in the second degree, which need not necessarily be so punished. The former included deliberate murder, in which there could be no doubt as to the intention; the latter, murder committed for facilitating escape from the consequences of other crimes and upon officers of the peace in the execution of their duty. One provision in the Bill would give the judges power to record the judgment without pronouncing sentence; and the recommendations of the Royal commissioners were also adopted with respect to infanticide and to public executions, the scenes at which were so disgraceful that some attempt was absolutely necessary to put an end to them. The Bill, after some discussion, was read a second time.

HOUSE OF COMMONS.—APRIL 27TH.

THE following petitions were presented:—By Sir James Fergusson, from the Ayrshire Poor-law Association, in favour of the Poor-law Officials' Supprannation, and praying for certain amendments. By Lord J. Browne, from the Swineford Board of Guardians, county Mayo, praying to be relieved from half of the cost of the salaries of the medical officers and school-masters of the Poor-law Unions, as in England. By Mr. H. Lewis, from the inhabitants of the borough of Marylebone, against compulsory vaccination and for full inquiry. By Mr. Alderman Cowen, from Josiah Thomas, Newcastle-on-Tyne, for inquiry into the operation of the Vaccination Act. By Mr. Evans, from John Smedley of Lea Mills, against compulsory vaccination, and in favour of a Royal commission on the subject. By Mr. Hanbury, from Robert Hawks, against the Vaccination Bill. By Mr. Milner Gibson, from the Poor-law Guardians of Ashton-under-Lyne, praying that unaffected districts may contribute towards the compensation for cattle slaughtered under the Cattle Diseases Act.

APRIL 30TH.

Mr. VILLIERS, in answer to a question, said that a measure for amending the administration of the poor-law in the metropolis would be laid in a short time on the table of the House, with a view of carrying into effect as far as possible the recommendations of the committee which sat upstairs. With respect to the conduct of the guardians of Clerkenwell he might state that a new board had been elected, and he hoped that more effectual measures would in future be taken for providing proper accommodation for the houseless poor.

THE UNIVERSITY OF LONDON.

In going into committee of supply, after a long discussion, in which several members joined, £20,000 was voted, without a division, towards erecting a building for the purposes of this institution. The edifice is to be erected on the north side of the gardens attached to Burlington House.

THE CATTLE PLAGUE.

Mr. CHEATHAM asked the Secretary of State for the Home Department if the Government would suspend the operation of Part I. of the Cattle Diseases Prevention Act, relating to the slaughtering of animals and compensation for the same, after the 10th of May.

Sir G. GREY said that originally it was intended that these clauses should only remain in force for a certain time, the order in council continuing their operation till May 12. The Privy Council had not considered the question of extending the time, but he thought that probably, owing to the great advantage that had been derived from observing these regulations, an order would be made for continuing them in force.

CONTAGIOUS DISEASES BILL.

The House having gone into committee on this Bill, Clauses 1 to 14 were agreed to.

On clause 15 Mr. AYRTON proposed an amendment.

Mr. HENLEY asked why the Bill should not be extended to Westminster, where there were troops.

Sir G. GREY said the Bill applied to places where either of the services constituted a considerable portion of the population.

MAY 2ND.

The Contagious Diseases Bill was read a third time.

CHOLERA IN CORK HARBOUR.

Mr. MAGUIRE wished to place a matter of great urgency before the house. The authorities of the city of Cork had been for some time in the communication with the Lord Lieutenant, and he had been recommended to place an old man of war in Cork harbour as a floating hospital. For three or four days he had himself been in communication upon the subject with the Secretary for Ireland, and he had just received this telegram from the mayor of Cork:—"Cholera is on Board an emigrant ship which has arrived in Cork harbour. There were two deaths among the passengers. There is no convenience for quarantining. I have ordered her back to Liverpool." There was a large garrison and a fleet in Cork. It would be a most calamitous thing if, for want of proper precautions, the disease broke out at Queenstown or Cork (hear, hear). He could tell the government upon the authority of the mayor of Cork and the local magistrates, that there were no means of maintaining a strict quarantine in the harbour, and he now called upon the government to do as they did in 1833, and send to that harbour a large and convenient vessel to answer the purpose of an hospital, and thereby to keep the disease away from the shore (hear, hear).

Sir G. GREY could only express his regret that the Mayor of Cork had not done as the Mayor of Liverpool had done—namely, communicated with the Government as to the facts of the case, with a view to the necessary arrangements being made to prevent the spread of cholera. The Government had heard nothing whatever from Cork on the subject. About an hour ago they had received a communication, by telegram, from the Mayor of Liverpool, stating that cholera had appeared amongst some German emigrants, and that the ship on board of which those emigrants were had touched at Queenstown. The Mayor asked that immediate measures should be taken by the Government to prevent the spread of the disease to Liverpool. He (Sir G. Grey) immediately forwarded that information to the officer of the Privy Council who was charged with the duties connected with quarantine, and his right hon. friend the Vice-President had just told him that he had taken steps with a view to the necessary measures being adopted. The only reason why the necessary measures had not been taken in Queenstown was that the Government had received no information of the disease appearing there. He had no doubt that the same steps would be taken with regard to Queenstown as had been taken at Liverpool.

Mr. MAGUIRE explained.—The local authorities in Cork had been in communication with the Lord Lieutenant on the subject for the last week, and within the last three days he (Mr. Maguire) had communicated the facts to the Chief Secretary for Ireland, who promised his attention to the matter (hear).

Sir G. GREY said that no information had reached the Government, that cholera had appeared on board any British ship except on that at Liverpool.

Sir F. HEYGATE was about to ask a similar question in reference to the port of Londonderry, where considerable alarm prevailed lest the disease should appear there.

Sir G. GREY said the Government had received no information on the subject from Londonderry.

Mr. AYRTON hoped that the Government would do nothing so cruel as to put cholera patients into a ship, or keep cholera patients in a ship.

TOOTH CEMENT (STEHLE).—Gutta percha, 5 parts; white wax, 1 part; oil of cloves, a few drops. (*Wittstein's Vierteljahresschrift f. Pharmacie* p. 2. xiv.) Another (Sorel):—A light oxide of zinc is prepared by moistening the ordinary oxide with nitric acid, and then igniting it. Thus prepared, it is made into a soft paste with a solution of chloride of zinc, having a specific gravity 1.9 or 2.0. This soft mass speedily acquires great hardness, which it permanently preserves. If a grey colour is required, the least trace of carbon may be used, got by holding the pestle with which the paste is made over the gas for a moment. A trace of sulphide of cadmium will produce a yellow tint.—*Year-Book of Pharmacy.*

PROFESSOR STRUTHERS ON THE EDINBURGH ANATOMICAL SCHOOL.

ON Friday evening, the President and Fellows of the Royal College of Surgeons gave a *conversazione* in the Surgeons' Hall, at which Professor Struthers, F.R.C.S.E., delivered a lecture on "The History of the Edinburgh Anatomical School." The company, which was very large, included the following gentlemen:—Lord Deas; Dr. Duns-mure, President of the Royal College of Surgeons; Dr. Smith, President of the Royal College of Physicians; Professors Christison, Syme, Balfour, and Spence; Bishop Strain; Dr. Graham, Dalkeith; the Rev. Mr. Rigg, Rev. James Cranbrook, Rev. D. Croom, Dr. Matthews Duncan, Dr. Coombe; Dr. Manford of Inverness; Dr. Baker of Birmingham; Bailie Handyside; Councillors Mossman, Marshall, Scott, and Colston; Messrs. Scott Moncrieff; S. Douglas, W. S.; J. W. Tawse, W. S., &c.

The following is an abstract of Professor Struthers' lecture:—

The history of the Edinburgh Anatomical School, properly so-called, commences in the year 1720, with the first Monro, Long before this, however, there had been dissection and occasional anatomical instruction in Edinburgh.

THE SURGEONS IN 1505.

The earliest notice of dissection in Edinburgh is in the first charter of this college, granted by the Town Council in 1505, and ratified by James IV. in the following year. The candidate for admission was to be examined in anatomy, and the surgeons were to have a body once a year for dissection. This was more than a century before Harvey discovered the circulation of the blood, and it is remarkable that the municipal authorities of Edinburgh should have at so early a period given legal recognition to dissection, as the groundwork of the healing art. We have no information of any change during the next two centuries. Medical education was by apprenticeship, with these occasional dissections by the surgeons for the instruction of themselves and their apprentices.

DEVELOPMENT OF THE SCHOOL—1694 to 1720.

During the quarter of a century preceding the commencement of a regular school, certain of the surgeons were specially appointed to conduct the annual anatomical demonstration. To Alexander Monteith belongs the merit of stimulating his brethren to the work in 1694, although I am not satisfied that he actually taught anatomy himself. During the first part of this period, the annual demonstration was given by ten of the surgeons, on ten successive days. The Town Council had not only granted the surgeons' petition for greater opportunity of dissection, but stipulated that the surgeons should build an anatomical theatre, and that the magistrates should have the privilege of being present at the demonstration.

A different system was employed during the last fifteen years of this period, the duty being now devolved upon one, or on two, of the surgeons specially appointed; and, at the same time, a new element is introduced by the Town Council conferring upon the same surgeon, or surgeons, the title of Professor of Anatomy in the University. During the first three years, this double appointment was held by Robert Elliot; during the next seven years, by Elliot and Adam Drummond; and, after Elliot's death, by Drummond and John McGill, till 1720, when Drummond and McGill demitted in favour of Monro, being but too glad to be relieved from an office which was more arduous than remunerative.

The harmonious action of the two bodies in making and agreeing to these double appointments was no doubt greatly promoted by the circumstance that the President of the surgeons (or Deacon, as he was then called) had a seat at the Council Board, a connexion which continued till the Burgh Reform in 1833. The chief object in seeking also the appointment from the Town Council, in the cases of Elliot, Drummond, and McGill, appears to have been to obtain the small salary which the Council gave with the title of Professor of Anatomy in the University; but, in Monro's case, the University appointment was his chief object, as part of the plan now on foot for the formation of a regular school; the best way to which was by obtaining the use of the theatre and subjects belonging to the surgeons, and at the same time the friendship of the Incorporation, and its support with the Town Council.

COMMENCEMENT OF THE MEDICAL SCHOOL.

After the appointment of Monro in 1720, the scheme rapidly developed. Four physicians—Drs. Sinclair, Rutherford, Plummer, and Innes—joined Monro in the surgeons' theatre. Left behind by the removal of Monro five years afterwards to the University buildings, they petitioned the Town Council to be made Professors in the University. This the Council did on the 9th February, 1726; and thus the medical school of the University was formed by the transference of the school which Monro had gathered round him in the theatre in Old Surgeons' Hall.

The first correct history of this development period, as it may be called, of the school was given by Dr. Gairdner in his two addresses before this College in 1860 and 1864, on the history of this College, and on the early history of the medical profession in Scotland. Dr. Gairdner kindly placed the original documents at my disposal; but the preceding very brief notice of this period will suffice to explain how matters stood before a regular school sprang up. I wish to mention that Dr. Gairdner has also, with the greatest kindness, otherwise done much to lessen the disadvantage at which distance has recently placed me in regard to consulting the records of this College and of the Town Council, for the proper subject of my lecture.

Looking back at this history, we are struck, first, with the early enactment of dissection, and then, notwithstanding, by the long period during which no progress was made, although during these two centuries anatomical teaching and science had made great progress on the Continent—in Italy, Belgium, Holland, and France. During this time, Vesalius, Fallopius, Sylvius, Columbus, Eustachius, Cœsalpinus, Fabricius, Malpighi, and other anatomists of fame, had flourished. Harvey had discovered the circulation of the blood a century before, and had been dead since 1658; and yet Edinburgh, which was in a comparatively short time to surpass all other schools in reputation, was during all this time without either school or anatomist of fame. For the explanation of this long delay we need not go farther than the condition of Scotland—miserably poor, and distracted by frequent war. The efforts which began with Monteith in 1664 are accounted for by the circumstance that, in that year, the powers of this College were extended from the city to a considerable part of Scotland; but even then the political condition of Scotland offered little encouragement to the cultivation of science. The union with England took place only in Elliot's time; and it was twelve years after this that the school was opened by Monro.

Even then the formation of the school was due—I find more than has been yet acknowledged—to the forethought and guidance of one whose name deserves mention and honour. This was John Monro the father of Alexander Monro, an army surgeon, of good Scotch family and education. He had settled in Edinburgh in 1700, and joined the surgeons. An able, accomplished, and amiable man, he rose high as a practitioner, and was President of the surgeons, in 1712-13. As a surgeon to King William's army, he had seen the necessity for improved medical education, and, as a travelled man he knew what medical education was on the Continent. His affection for his only son, and his desire to see a medical school established in Edinburgh, became united in the idea of his son being the instrument. It was henceforward the idea of his life. He educated his son for it, and when the time came communicated his plan to the surgeons and physicians, by whom it was well received. It was part of his plan to persuade others to join with his son: and, when the college part of the scheme was fairly launched, he saw the necessity for an hospital, and set his son to write and work for it. To this farseeing and good man must be assigned the merit of the idea, and of being the organiser of the scheme, the success or failure of which was to depend on his son.

ALEXANDER MONRO.

Young Monro's education was planned by his father with a view to his becoming teacher of anatomy. After receiving all that Edinburgh could then give, he was sent at the age of twenty, to London, Paris, and Leyden, between which he spent two years in the study of anatomy and other branches of medicine.

He came under the influence of two eminent men—the great Boerhaave, in Leyden, under whom he studied the practice of medicine; and, in London, Cheselden, who was Monro's true master and inspirer as anatomist and teacher. Cheselden had already been teaching anatomy and surgery

for seven years, was an enthusiastic teacher and eloquent lecturer, and, above all, encouraged the students to observe and think for themselves. Nine years Monro's senior, they were kindred spirits, and formed a lasting friendship. Here Monro nearly lost his life from the effects of a dissection wound.

Returning to Edinburgh, he was examined and admitted by the surgeons; and two months thereafter—on the 29th January, 1720—being in his 23rd year, was elected Professor of Anatomy in the University by the Town Council, on the unanimous recommendation of the surgeons.

Great exertions having meanwhile been made by the father to attract notice to his son's approaching course, he began with fifty-seven students. He continued to teach for five years in the theatre in Surgeons' Hall, when he removed to the University Buildings, the removal being for greater security to his museum, his establishment in Surgeon-square having been threatened by a mob, which it required the energy of the magistrates to quell.

The attendance on Monro's class is interesting, as probably indicating the total number of students of medicine then in Edinburgh. During the first ten years, the average attendance was 67, the maximum 90; during the second ten years, the average was 109; during the third ten years, 147: In 1745, the year of the Rebellion, the number fell from 150 to 76; but in the following year rose to 182—the largest class he had yet had. In round numbers, we may say Monro began with 50 students, and had raised the number to 200 before he retired, after thirty-eight years' teaching.

Six years after he had begun to teach, Monro published his great work on the human bones, which underwent eight editions in his lifetime, and was translated into most of the European languages. The early publication and great reputation of this work must have tended materially to give fame to the Edinburgh school. This work, it is interesting to know, had its origin in one of the essays at the Student's Society which met in Cheselden's class-room, in which Monro had been a leader.

All Monro's writings have been reprinted in one large quarto volume. They are full of fact and thought, expressed in few and plain words. It is, however, impossible for me, in the limits of this lecture, to give anything like an analysis or critical notice of the writings of the various anatomists of whom I have to speak, or to do more than merely allude to them.

As a practitioner Monro took his turn as one of the surgeons attending the hospital, and gave lectures on the surgical cases. In private practice he does not appear to have been an operating surgeon, at least in the greater operations; but his advice was frequently sought as that of a scientific practitioner in all kinds of cases. Of fifty-five papers or essays, in his collected writings, there are, in anatomy and physiology, seventeen; in surgery, nineteen; in medicine, fifteen; in midwifery, four. As evidence of his judgment as a practitioner, I would mention particularly his paper on "Cancer of the Breast," in which he expresses those doubts and views which, after the lapse of a century, surgeons have now come to entertain.

Monro has the chief merit also in the establishment of two of our institutions. Various public bodies took part in establishing the Royal Infirmary, but Monro and Lord Provost Drummond were the active spirits of the movement. When the present building was at last commenced, in 1738, they were the "Building Committee," and regularly paid out the workmen's wages with their own hands. Hence the Professor of Anatomy is *ex-officio* a manager of the Royal Infirmary.

The other was a medical society which, after publishing several volumes of essays and passing through an intermediate stage as the "Philosophical Society," was finally, in 1782, incorporated as the Royal Society of Edinburgh.

After resigning the duties of the anatomical chair to his son in 1758, in his sixty-first year, Monro devoted himself during the remaining nine years of his life to practice, and to more regular clinical teaching at the Infirmary—more now, I infer, as a physician than as a surgeon.

Monro is invariably referred to as having been, in every relation of life, a most admirable and lovable man—sincere, modest, without jealousy, benevolent, an able and active and at the same time a calm and placid man. He had family and friends influential and plenty, but the work he had to do was of a kind at which friends could only stand and look on. He had to do a new thing in Edinburgh—to teach

anatomy, and provide for the study of it in a town of then only 30,000 inhabitants, and in a half-civilised and politically disturbed country. He had to gather in students, to persuade others to join him in teaching, and to get an infirmary built. All this he did, and at the same time established his fame, not only as a teacher, but as a man of science, and gave a name to the Edinburgh school, which benefited still more the generation which followed him. This really great and good man, therefore, well earned the title often given him, of father of the Edinburgh School.

OPENING OF THE SURREY COUNTY HOSPITAL.

THE Surrey County Hospital, which is said to owe its origin mainly to the clergy of the district, was inaugurated on Friday, by the Lord Bishop of Winchester, in the presence of a large assemblage of the neighbouring gentry and others. The building is situated about five minutes' walk from the Guildford station of the South-Western Railway, and stands on an eminence, commanding an extensive view of the surrounding country. It is a neat unpretending structure, some 260 feet long and about 80 feet high, with a façade of Bargate stone and bright red brick dressings. The internal design of the building is of a nature to be in every particular admirably adapted to the purposes for which the structure is intended, while the different departments are fitted with all the modern appurtenances necessary in such institutions.

The ceremony of dedication took place in a marquee erected for the time being in the rear of the hospital.

The company then proceeded to the entrance hall of the hospital, where the ceremony of uncovering the bust of the late Prince Consort was gone through. The bust, which is a beautiful work of art by Mr. Theed, stands on a marble pedestal on the right of the hall staircase, enclosed by a neat gilt railing. As soon as the veil was removed from the bust,

The Lord Bishop said—As the hospital is opened this day, and honoured by the bust of the late Prince Consort—honoured at the express desire of her Majesty—I think it will be right in us to show our feelings, not merely of loyalty but of affection, as subjects of one of the best Queens that any nation ever had, and express them by three cheers and one cheer more.

This expression was heartily responded to by all present.

A fair proportion of the company afterwards adjourned to the eastern, or male ward of the building, where they sat down to a collation presided over by Mr. Bateman, the high sheriff of the county.

The usual loyal toasts were given and duly responded to.

The Rev. Mr. Hatchard then said he had to inform the company that her Majesty had not alone consented to allow herself to be placed at the head of the hospital as its patroness, but had sent them a donation of 100 guineas. He then read the following communication from her Majesty:—"SIR,—I have submitted your letter to the Queen, and I am commanded to say in reply that although her Majesty finds it necessary to decline her patronage in most cases to purely local institutions, except in places adjacent to where her Majesty resides, an exception will be made in favour of the Surrey Hospital, to which her Majesty graciously consents to become a patroness, and commands me to forward a donation of 100 guineas.—I have, &c., "T. M. BIDDULPH."

The Bishop of Winchester having spoken in general terms upon the merits of the institution and its promoters, commending the former to the general support of the county at large, proposed "The Health of the Chairman."

The Chairman briefly acknowledged the compliment. The Ven. Archdeacon of Surrey then gave "Success to the Royal Surrey County Hospital." In the course of an able speech he said he felt that the success which had attended it was owing to the great support given by the public, and the constant and individual labours of the committee. He also mentioned with admiration the efforts of the ladies who raised £1900 by the bazaar last year,

and thus enabled the hospital to start on its mission free of debt.

Mr. H. B. Clarke, in the absence of the treasurer, through illness, made a financial statement, from which it appeared that the donations and subscriptions up to the present time amount to £14,962, to which were to be added £1904, proceeds of the bazaar, and £535, Mr. Hatchard's bed fund; total, £17,401. The total cost of the building had been £15,015, and of furnishing, £2000— together, £17,015, which left a balance of £386.

The Chairman, in proposing "The Health of Earl Onslow and other Donors of the Hospital," alluded to the act of his lordship in presenting the committee with part of the site on which the hospital stood, and expressed a hope that £2000 a year, the estimated cost of its maintenance, would be forthcoming.

"The Committee" and "The Medical Staff" were then respectively proposed and responded to by the Rev. C. R. Dallas and Mr. Clark, the senior consulting surgeon to the hospital; and the proceedings subsequently terminated.

QUININE A CONSTITUENT OF THE BODY.

It is too soon to say that chemists have discovered that quinine is a natural constituent of the body; but they have found in the textures of the body of the guinea-pig a substance which they find it hard to distinguish from quinine. The discovery came about in an unexpected way. Dr. Bence Jones and Mr. Dupré were making experiments with a view to ascertain the rate at which substances passed into and out of the textures. They chose quinine because of its effect, or rather the effect of an acid solution of it, upon light. Quinine was given to one guinea-pig and withheld from another. Both were killed. The organs and tissues of each were subjected to a process of heating in a water bath with very dilute sulphuric acid; and from the tissues of the one that had not taken quinine was extracted a fluorescent substance, the solution of which acted on the spectrum almost precisely as the solution of quinine. Not only by the mode of its extraction from the tissues and its behaviour towards light was this substance not to be distinguished from quinine, but in its chemical reactions with various other substances it very closely resembled the alkaloid of cinchona. For the present it has received from the above gentlemen the name of Animal Quinoidine, and is supposed by them to be one of the earliest products of the downward passage of albumen.

It will be very remarkable if organic chemistry does not confirm this discovery, and assure us of the existence of a substance in the human body not to be distinguished from quinine. We have not much confidence yet in organic chemistry as an exponent of physiological and therapeutical facts. But this is merely because of its imperfection; and we cannot doubt that as it becomes more perfect it will diminish the number of facts which do not admit of explanation. One of these at present is the action of quinine in the cure of ague. This is almost the only specific we have; and, in its unique isolation, it has always been curiously regarded by scientific physicians. We ourselves have been at a loss whether to regard it as an earnest of other specific remedies yet undiscovered, or to view the fact of there being one specific remedy as (so to speak) a mere accident, not justifying the hope that disease generally was ever destined to be treated and cured by specifics. Of course there was always the possibility of some explanation of its action being given; and already it seems possible that we are close upon it. Chemistry may be about to show us that quinine acts by supplying artificially a natural substance which is temporarily deficient or absent in the system, as the effect of marsh poison or other causes. This is Dr. Bence Jones's theory. We are terribly at the mercy of organic chemists in this region of science. They will forgive us if we receive their speculations with considerable doubt; we can only assure them that our doubts is largely mingled with gratitude. Dr. Bence Jones's own account of this matter was lately given in a lecture at the Royal Institution.—*Lancet*.

THE MEDICAL COUNCIL.

ON Thursday week next, May 17th, the Medical Council will meet at the Royal College of Physicians. We could wish that before that time the amended Medical Act promised by Sir G. Grey were well on its way through the House of Commons. But we cannot learn that the timbers are fairly laid, so that it is difficult to state the day of launching the ship. The matter is understood to be now in the hands of Mr. Henry Thring, Parliamentary Counsel to the Home Office. We know that the business of parliamentary counsel to that office is no light one; but we have been waiting the good pleasure of Mr. Thring for some time now, and as the Bill to be drafted is by far more important than it is complex, we can but hope that the present delay will be soon brought to an end.

An effort will probably be made to render the application of the regulations requiring a preliminary examination more stringent; but if no protection be given, increasing stringency will not be peculiarly acceptable. Last Monday Mr. Holland, the member for Evesham, brought in a bill which will shortly be read a second time, providing that no person who is not a member of the Royal Veterinary College of Surgeons shall be permitted, under certain penalties, to call himself a "veterinary surgeon." We have serious doubts whether horses and their ailments can properly be considered entitled to precedence over human beings and their disorders, but no doubt a good many friends of the stable will give the Bill their warm support on the second reading.

The Pharmacopœia is still *in limbo*. Unhappily, Mr. Warrington has been for some months seriously indisposed, but whether the Pharmacopœia ought to have been kept waiting so long, and purchasers of the Pharmacopœia indulged with so many copies of a book which is only published to be superseded, is a question on which the profession will probably differ in opinion from the committee. At any rate the profession suffer by the delay, for such of them as want a Pharmacopœia are put off with a book which will soon be comparatively useless.—*Lancet*.

TREATMENT OF LUNATICS IN FRANCE.

A REPORT addressed to the Emperor Napoleon by the Minister of Commerce and Public Works on the lunatics confined in public and private asylums throughout France, contains some interesting facts.

The number in each of the lunatic asylums on the 1st of January was on an average 305. Taken separately, some contained from 1000 to 1300 patients, and others not more than 20. The largest lunatic asylum in Paris is the Salpêtrière, where there were 1362 patients on the 1st of January, 1861. A census was taken throughout France on the 1st of January, 1851, the 1st of January, 1856, and the 1st of January, 1861, of all lunatics, distinguishing those treated at home from those in the asylums. It appeared that in 1851 there were 24,333 lunatics treated at home and 20,537 in asylums; in 1856, 34,004 at home and 26,286 in asylums and in 1861, 53,150 at home and 31,054 in asylums. These returns show that the lunatics increased within ten years from 44,970 to 84,204. Further returns show that the greater number of idiots are treated at home, and that the lunatics are sent to asylums. By comparing the number of lunatics and idiots according to their sex with the entire population, it will be found that there is one male lunatic for 915 men and one female lunatic for 839 women; and secondly, that there is one male idiot for 796 men, and one female idiot for 1034 women, showing that there are fewer lunatics among men than among women, and that there are fewer idiots among women than among men. The Minister directs the attention of the Emperor to the greater mortality among men than among women in lunatic asylums. The average is 130 deaths among men to 100 among women. The four-fifths of the patients admitted into lunatic asylums are supported by public charity at an expense of a little more than 1s. a head per diem.

SOME French chemists have succeeded in obtaining oxalic acid from the waste of shoemakers' and saddlers' shops.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

THE annual general meeting of the members of this Society was held at 53, Berners-street, London, W., on the 26th ultimo. The balance sheet for the year 1865 was read, from which it appeared that some sixty-five widows and orphan children of deceased members of the Society had received during the year ordinary relief to the extent of £2150, besides other grants.

The following officers and directors were selected for the following year:—

President.—Mar. in Ware, Esq.

Vice-Presidents.—Everard A. Brande, Esq.; Peter M. Latham, M.D.; John Bagot, Esq.; D. Henry Walne, Esq.; A. J. Suthe-land, M.D.; F.R.S.; George Burrows, M.D.; F.R.S.; John Miles, Esq.; C. H. Hawkins, Esq.; F.R.S.; James Paget, Esq.; F.R.S.; Charles Hawkins, Esq.; Thomas Hamerton, Esq.; Sir Charles Lecock, Bart.; M.D.

Treasurers.—James Thomas Ware, Esq.; George Hamilton Roe, M.D.; Richard S. Eyles, Esq. (Acting.)

Directors.—Henry Sterry, Esq.; Henry Jeaffreson, M.D.; H. S. Illingworth, Esq.; Francis Hawkins, M.D.; T. B. Curling, Esq.; Jno. Hilton, Esq.; Jno. Love, Esq.; Henry A. Pitman, M.D.; John Adams, Esq.; Robert Druitt, M.R.C.P.L.; J. C. Foster, Esq.; Edward Tegart, Esq.; John Quain, Esq.; Henry Lee, Esq.; C. Collambell, Esq.; Richard Scott, M.D.; George Johnson, M.D.; C. F. Du Pasquier, Esq.; E. N. Berry, Esq.; Samuel Solly, Esq.; John Morgan, Esq.; Richard Barres, M.D.; George Budd, M.D.; Wm. Bowman, Esq.

The annual dinner is appointed to be held on the 16th inst., for particulars of which, and the district within which medical men must live to become members of the Society, we refer to the advertisement in our present number.

We hope that many of our readers will join this most useful Society.

REPRESENTATION OF THE MEDICAL PROFESSION IN PARLIAMENT.

WE would remind our readers of our article on this subject which appeared on the 14th of February last.

The question is now raised as to the redistribution of seats; some of the boroughs are thoroughly corrupt, and probably many will be disfranchised. No party in the State is likely to object to representatives for the Medical Colleges. It is, as we showed, the interest of all and an injury to none. The only reason why it is not granted is that it is not asked. Let the profession be unanimous in asking for representatives, and put forward their claim, and Parliament will easily learn the propriety of granting a reasonable request.

COUNTY AND CITY OF CORK MEDICAL PROTECTIVE ASSOCIATION.

At the Committee's meeting of to-day (May 5th), communications were read from Drs. Mackesy, Edgar (of Fermoy), Sandiford (of Castlemartyr), Madras (of Coachford), and Manby (of Leeds).

Dr. Mackesy says:—"To express deep obligation and sincere thanks to the President and Members of the County and City of Cork Medical Protective Association for their kind resolution of sympathy."

Dr. Edgar writes:—"I enclose my subscription and that of Dr. Blacquiere for the current year, and assure you that the rules and exertions of the Association merit my strongest approval."

Dr. Sandiford says:—"In enclosing my subscription allow me to say how very deeply I feel the benefits which this Association confers on the profession, and as a Dispensary Medical Officer, I am very grateful for its exertions on our behalf."

Dr. Madras alluded to the attempts being made, in some localities, to render the Dispensary Medical Officers Assistant Relieving Officers, and asked for a copy of a letter ad-

ressed to the Dispensary Medical Officers of Cork by the Poor-law Commissioners on the subject. Instructions were given that Dr. Madras be supplied with a copy of the letter.

Dr. Mauby's letter is dated West Bromwich, Staffordshire, April 25, 1866:—"Will you kindly send me a copy of the last report of the Cork Medical Protective Association. I am Secretary to our local Society, and though we have done little hitherto, I am anxious to interest the members in matters not purely professional, but ethical and political."

The Chairman read an article from a recent number of the *Lancet*, referring to the Medical Reform Council of this country, and contrasting it with that of Canada, which elicited a warm discussion that terminated in its being unanimously resolved—"That a special meeting of the Association at large, called by special summons, be held on the 12th inst., to consider this important question, with a view of immediate action pending anticipated legislation on the matter."

A sub-committee having been appointed to arrange matters for the consideration of the special meeting, the proceedings terminated.

PRECAUTIONS AGAINST CHOLERA IN SOUTHAMPTON.

SINCE the receipt of the circular recently issued by the Quarantine Department of the Privy Council to the authorities of the various towns and ports of England several meetings of the Sanitary Committee of the Southampton Corporation have been held, with the view of adopting any necessary steps to give effect to the Government letter. In their deliberations the committee have had the advantage of the advice of Dr. Parkes, Professor of Hygiene at Netley Hospital; Dr. Wiblin, the superintendent of quarantine at this port; and Dr. McCormack, the newly appointed officer of health. At the quarterly meeting of the corporation, held last week, Mr. Alderman J. R. Stebbing, chairman of the Sanitary Board, brought up its report, recommending that a deputation be authorized to proceed at once to the Privy Council-office in London, and represent to the authorities there the remarkable circumstance that beyond due attention to the sanitary condition of the borough itself no steps could be taken at this or any other port in the United Kingdom to protect any of the seaports of England from the effects of cholera prevailing in any ship or vessel arriving in this country from abroad; that while the superintendent of quarantine can, as to yellow fever and certain other specified diseases, exercise the most complete authority over the vessel, the sick, or dying, and prevent any communication with the shore either of individuals or their effects he has no such authority in respect to cholera, and that, despite that officer's authority, both dead or dying, sick or well, and (what is from modern experience known to be almost as serious) their clothes and effects may be landed at this or any other port, and cholera patients be thus spread all over the coast of England. The corporation immediately confirmed the view of the Sanitary Committee, and an early interview with the Privy Council department of the State has, we believe, been arranged by a preliminary deputation consisting of the medical gentlemen above referred to, who proceeded to London to confer with Mr. Simon, superintendent-general of the quarantine department of the Privy Council, immediately after their interview with the Sanitary Board. It is satisfactory to add that every precaution has been taken in the town itself for the prevention of sickness. All the courts and alleys are limewashed, lodging-houses cleansed or closed, gullies and drains trapped and deodorized, all the nuisances reported by the house-to-house visitation at the close of last year have been removed, with a few exceptions still in progress, and a permanent staff of one medical officer charged with the health of the town, one principal inspector of nuisances, and four assistant inspectors, who devote their whole time to sanitary measures, are actively engaged in the important duties, in addition to the services of Dr. Wiblin, the Government superintendent of quarantine at this port.—*Times*.

Notices to Correspondents.

X. Z.—The *atmograph* is a newly-invented instrument for measuring and recording the respirations. The word signifies properly a vapour or exhalation, but it also means the *breath*.

A Sufferer.—We do not recommend the operation in question, nor do we believe that it is so generally successful as is asserted.

Dr. J. T.—To believe that such a medicine has any curative effect on valvular disease of the heart is a sheer fallacy, about which it would be idle to argue.

Expectans.—It has been decided that the hospital is not to be removed, the site having been refused by the authorities.

The Society for the Relief of Widows and Orphans of Medical Men.—The list has been received.

The Westminster Hospital Medical School.—The card and the communication have been received.

Dr. L.—The pamphlet has been received.

A Surgeon.—The candidate must possess a licence to practise medicine as well as surgery.

Querist.—There is no law to compel the coroner to follow the plan indicated.

M. R.—The newspaper has been received.

Medical News.

THE friends of Mr. William Turner, the accomplished and respected Demonstrator of Anatomy in the Edinburgh University, will be pleased to learn that he has been appointed Examiner in Anatomy to the University of London, a post which his long experience and distinguished abilities render him peculiarly well able to fill.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted Members of the College, at a meeting of the Court of Examiners on the 26th ult. :—

Blythman, Clement Samuel, Swinton, Yorkshire.
Bowkett, Thomas Edward, Poplar.
Buckley, Henry Child, Llanelly, Carmarthen.
Coalbank, Isaac, Old Dalby, Leicestershire.
Cooke, James Lawson, Market, Drayton.
Gray, Alexander Riddoch, M.A. and M.B. Aberdeen.
Hill, Arthur, L.S.A., Pimlico.
Hughes, James Brierly, Congleton, Cheshire.
John, William, Haverfordwest.
Kelly, Charles, Market Deeping.
Lamb, Barnabas Walter, Stourport, Worcestershire.
Malins, Edward, Liverpool.
Monckton, William, Brenchley, Kent.
Parsons, Frederic William, Bayswater.
Pattinson, Henry Beaumont, Hcavtree, near Exeter.
Richards, William Joseph, Redruth, Cornwall.
Tattersall, William James, Bacup, Lancashire.
Taylor, Moses, Walsall, Staffordshire.

At the same meeting of the Court

Thomas David Bowen, Greenwich Hospital,

passed his examination for naval surgeon; this gentleman had previously been admitted a member of the College, his diploma bearing date April 11th, 1861.

The following gentlemen were admitted Members on the 27th ult. :—

Airey, George, Bayswater.
Carter, William, M.D. Edin., Mid-Calder, Edinburgh.
Chapman, George, Brierley Hill, Staffordshire.
Davies, William, Llanpumpain, Carmarthen.
Dunn, George Newman, Dublin.
Exell, Edmund, Yeovil, Somerset.
Hayden, James Augustus, High Wycombe.
Heelas, Martin Luther, Wokingham, Berkshire.
Hiron, William Nathaniel, Chipping Campden.
Hott, John James, L.S.A., Bromley, Kent.
Kenyon, George Arthur, Doncaster.
Maybury, Augustus Constable, Frimley, Surrey.
Oakman, Joseph, Wimbledon.
Raine, George Rolph, Billericay, Essex.
Read, Arthur Walter, Coventry.
Riley, Joseph, Barnes, Surrey.
Smith, Joseph William, Weaverham, Cheshire.
Thomson, Henry Albert Richardson, Spenser-square.
Thurston, William French, Notting-hill.
Watson, Samuel Key, Jersey.
Withers, Richard Walter Owen, Shrewsbury.
Wright, Robert Temple, Norwich.

It is stated that twelve, of the ninety-eight candidates who offered themselves for examination, failed to acquit themselves to the satisfaction of the Court, and were consequently referred back to their hospital studies for six months.

The following gentlemen passed their Primary Examinations in Anatomy and Physiology at a meeting of the Court of Examiners on the 1st inst., and when eligible will be admitted to the Pass Examination :—

George Vawdrey, William Turner, E. S. Pearce, A. C. Taylor, R. E. Daniel, J. G. Hurford, John Guy, and J. A. Bevan, students of Guy's Hospital. W. B. Thorne, F. H. Waylen, T. E. Scobell, F. E. Aldrich, E. R. Johnson, and C. H. Newstead, of St. Bartholemew's Hospital. P. A. Young, A. D. Walker, and R. W. Toss, of Edinburgh. A. J. Baker and H. N. Chilcote, of the Westminster Hospital. A. P. Fiddian, of King's College. Richard Minors, of St. Mary's Hospital. H. G. Hall, of Dublin. Robert Pollock, of University College. George Moore, of Birmingham.

THE friends of the Rev. W. Clark, M.D., have determined to offer to the University of Cambridge a marble bust of that gentleman, to be placed in the Museum of Comparative Anatomy, which they wish the University to call the "Clarkian Museum" in honour of Dr. Clark, to whose exertions and liberality its existence is in a great measure due.

In consequence of the alarm excited by recent cases of hydrophobia, dogs have been "proclaimed" in Manchester and Salford some months earlier than usual, and within the last few days have been destroyed by the police with prussic acid.

THE Emperor of Morocco, in consequence of his late serious illness, has decided on creating, at Tetuan, Saffi, Tangier, and Fez, four large hospitals for the army and the poorer classes of the population. A French physician has been charged with the organization of those establishments, and has already arrived at Tangier.

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS, IRELAND.—In consequence of the meeting of the General Medical Council, the eighth meeting will be held on Wednesday, 9th May, 1866, tea at eight; chair to be taken at half-past eight p.m. *Communications.*—1. Dr. H. Kennedy—"On Mixed Types of Fever." 2. Dr. M. Eustace—"Cases of Insanity of Difficult Diagnosis, tending to Crime; with Observations." 3. Dr. J. Byrne—"A Case of Puerperal Fetid Abscess in the Lung."

THE DISEASE AMONG SHEEP.—An Order in Council has been issued, directing precautionary measures against the further spread of the disease among sheep.

ROYAL SOCIETY.....At the Royal Society's *Soiree* on the 28th ult., Dr. Bence Jones exhibited illustrations of the fluorescence of a certain substance, allied in its nature to quinine, inherent in the flesh of animals, the singular characteristic optical effects of which were shown in the extra violet rays of the electric light. Mr. Bateman discoursed on the water supply of London from the Plympton district. Professor Graham showed the process of the separation of the oxygen from the air by dialysis. The air from within an India-rubber bag is exhausted, and as the vacuum is continued by the descent of a column of mercury connected by a pipe with the bag, the air has a natural tendency to flow through the substance of the bag itself. The oxygen, however, being more soluble, so to express it, by the India-rubber than the other component of the air, the nitrogen, a portion of the oxygen of the air (about forty per cent.) passes through, and is carried down in globules by the column of mercury, and being collected in test tubes or other convenient receptacles, partially extinguished matches may be relighted, and other experiments illustrating the properties of oxygen may be performed.

BELFAST BRANCH OF THE ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.—The stated quarterly meeting of the Committee of this branch of the above Society was held on Wednesday, the 2nd inst., in 33, High-street, and was attended by the following members :—Dr. T. H. Purdon, permanent president, in the chair; Dr. Patterson, Dr. James Moore, Dr. Ferguson, Professor Cuming, M.D.; Dr. Keown, R.N.; Dr. Browne, R.N., treasurer; and Dr. Stewart, secretary. The treasurer reported having received subscriptions from Sir E. Coey; Dr. Johnson, Strangford; Dr. Musgrave, Lisburn; Dr. Thompson, Lisburn; Dr. McHarg, Lisburn; Dr. Campbell, Lisburn; Dr. Pirrie, Dr. Moreland, Dr. Murney, J.P.; Dr. Thomas Reade, Surgeon Thompson, Bangor, &c., and that the proceeds for this year in donations and subscriptions amounted to the present time to £80 nearly; that several of the supporters of the Society in town and country had not yet remitted their subscriptions, but which it was desir-

able should not be further delayed, the time having arrived for forwarding to the general treasurer in Dublin all funds in hands preparatory to the general annual meeting there next month. It was, accordingly, resolved that every effort should be used to collect in as immediately as possible all outstanding liabilities, and that subscribers and friends at a distance be requested by the secretary to forward their contributions at their earliest convenience. A letter was now read from Dr. Wharton, the esteemed and zealous general secretary, Dublin, announcing the holding of the ensuing annual meeting next month in the King and Queen's Royal College Physicians, Kildare-street, and intimating that, as the reports of the branch associations formed a main feature of the annual report, it was the anxious desire of the Parent Committee that the report of this one for the past year, the oldest of all the branches, should be forwarded to him as usual for embodiment in the Parent report; and, in accordance with which request, instructions were now given to the secretary to supply a statement of the operations of this branch for the past year to Dr. Wharton for the desirable purpose as stated in his official letter. The president, Dr. T. H. Purdon, and Dr. Browne, were requested to attend the annual meeting next month in Dublin on behalf of this branch, and express its entire satisfaction with the Society's management by the Parent Committee. This being the period of the year for recommending parties for grants at the annual meeting, several applications were now submitted, and, having been particularly inquired into, each was recommended for assistance as far as the limited funds at the disposal of the Society would admit of; and some further business having been disposed of, and the best thanks of the meeting given to the chairman for his always most generous support of this branch, and exertions in promotion of its truly benevolent objects, the meeting separated.

CLINICAL LECTURES.

In our present number we are enabled to furnish our readers with Professor Banks's Clinical Lecture on the "Origin and Classification of Fevers," which forms one of the important Course, or Fever Clinique, recently advertised to in our columns.

We have also to acknowledge the receipt of a Clinical Lecture by Dr. Duncan on "Acute Rheumatism." This may be regarded as necessarily connected with one by that gentleman given in our last number. We hope to publish it in our next.

Medical Diary of the Week.

LONDON—WEDNESDAY, MAY 9.

ROYAL COLLEGE OF PHYSICIANS.—5 p.m. Dr. Andrew Clark, "On some Points in the Minute Anatomy of the Lung; on the Theory of Pulmonary Hepatization; and on the States of Lung comprehended under the term Phthisis Pulmonalis."

MICROSCOPICAL SOCIETY OF LONDON.—8 p.m. Mr. Jas. Smith, "On a form of Rotating Leaf-holder."—Dr. Greville: "New and Rare Diatoms. Series 20"

THURSDAY, MAY 10.

ROYAL INSTITUTION.—3 p.m. Professor Huxley, "On Ethnology."

FRIDAY, MAY 11.

ROYAL COLLEGE OF PHYSICIANS.—5 p.m. Dr. Andrew Clark, "On some Points in the Minute Anatomy of the Lung; on the Theory of Pulmonary Hepatization; and on the States of Lung comprehended under the term Phthisis Pulmonalis."

ROYAL INSTITUTION.—8 p.m. Prof. Ansted, "On the Mud Volcanoes of the Crimea."

SATURDAY, MAY 12.

ROYAL INSTITUTION.—8 p.m. Professor Huxley, "On Ethnology."

WEEKLY METEOROLOGICAL REPORT FOR THE WEEK ENDING MAY 5TH, 1866.

By J. H. STEWARD, Strand, and Cornhill, London.

May, 1866.	Barometer reading reduced to 32 degrees.	Thermometer.		Dry bulb.	Wet bulb.	Wind.		Rain.	Remarks.
		Max.	Min.			Direction.	Force.		
30	29.080	45	36	48	48	E	—	000	Wind.
1	29.050	43	40	42	43	E	—	010	Rain.
2	29.050	56	37.05	42.05	43	N.W.W	—	008	Showery.

4	29.073	68	36	51	53	N.W	—	000	Pleasant.
5	30.007	65	38	54.05	53.05	W	—	000	Fine.

REPRINTS OF CONTRIBUTIONS.

ARRANGEMENTS have been made in our printing department by which Communications to THE MEDICAL PRESS AND CIRCULAR of sufficient length may, at the desire of their Authors, be reprinted from the pages of the journal in pamphlet form. *Twenty-five copies of the reprint will be presented free of cost, and any further number at a small charge.* Contributors are requested to intimate their desire for the republication of their Communications, and to specify the number of copies required, at as early a period as possible, as otherwise the type will be broken up.

Original Communications, Hospital Reports, Society Proceedings, and other matter of considerable length, should reach our Office not later than FRIDAY EVENING for insertion in the following Wednesday's issue. No exception to this rule can be made. Important information—Telegraphic News, and other matter occupying only a short space—can be received up to Monday evening.

Authors' corrected proofs must in all cases be returned to the Office not later than 10 o'clock on MONDAY MORNING, and no alterations can be attended to after that date.

MEDICAL APPOINTMENTS.

LONDON.

- S. J. B. CALDWELL, L.R.C.P. Ed., M.R.C.S.E., Senior Resident Medical Officer at the Liverpool Workhouse Infirmary, has been appointed Medical Officer and Vaccinator for No. 6 (Liverpool) District, vice Mr. A. R. Beckett, deceased.
- T. CREAN, L.K.Q.C.P.I., has been elected Medical Officer for the Brewood District of the Penkridge Union, Staffordshire, and for the Union Workhouse, Brewood, vice C. O. Gilby, M.R.C.S.E., resigned.
- N. E. CRESSWELL, M.D., has been elected Medical Officer and Public Vaccinator for the Biddenden District of the Tenterden Union, Kent, until March 25th, 1867, vice H. S. Hutcheon, L.R.C.P. Ed., resigned.
- E. P. DAVIES, M.R.C.S.E., has been elected Assistant Resident Medical Officer to the Carmarthenshire, Cardiganshire, and Pembrokeshire Joint Lunatic Asylum at Carmarthen.
- A. DUNCAN, M.B., M.R.C.S.E., has been appointed one of the Medical Officers of the City Parish, Aberdeen, vice D. Fiddes, M.D., resigned.
- A. GITTINS, L.R.C.P. Ed., Resident House-Surgeon to the Brighton and Hope Lying-in Institution.
- C. KELLY, M.R.C.S.E., Resident Accoucheur to King's College Hospital.
- H. L. KEMPTHORNE, M.D., late House-Physician to King's College Hospital, has been elected Assistant Medical Officer to Bethlehem Royal Hospital.
- C. W. PHILIPOT, L.S.A., B.Sc. Lond., House-Physician to King's College Hospital.
- S. J. CONNOR, L.K.Q.C.P.I., Medical Officer to the Carlow County Fever Hospital, vice W. H. Symes, M.B., C.M.Dub., deceased.

NEW WORKS IN MEDICINE AND SCIENCE.

- Churchill (Fleetwood)—On the Theory and Practice of Midwifery. 5th edit. corrected and enlarged. 12mo. pp. 840, cloth, 12s. 6d. (Reushaw).
- Copland (James)—The forms, Complications, Causes, and Treatment of Bronchitis. New edit. 12mo. pp. 170, cloth, 5s. (Longmans)
- Diseases (The) of Live Stock and their Remedies. 12mo. sewed, 6d. (Elliot).
- Ellis (Robert)—On the Safe Abolition of Pain in Labour and Surgical Operations. Post 8vo. cloth, 2s. 6d. (Hardwicke).
- Entomological Society—Transactions of. 3rd Series. Vol. 2. part 6. with 2 Plates. 8vo. sewed, 5s. (Longmans).
- Gray (H.).—Anatomy, Descriptive and Surgical. 4th edit. By T. Holmes. Royal 8vo. cloth, 28s. (Longmans).
- Miller (Jas.)—Physiology in Harmony with the Bible. New edit. 18mo. sewed (Hamilton).

Births, Deaths, and Marriages.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

BIRTHS.—LONDON.

- BLACKMORE.—On the 26th ult., at Douglas-road, Canonbury, the wife of Dr. Blackmore, of a daughter.
- WYMAN.—On the 26th ult., at the Grove, Highgate, the wife of W. S. Wyman, M.D., of Hatfield Broad Oak, of a son.
- PARROTT.—On the 27th ult., the wife of J. Parrott, M.R.C.S.E., of Clapham-common, of a son.

PROVINCIAL.

- MARSHALL.—On the 23rd ult., at Holly House, Mortlake, Surrey, the wife of W. Marshall, M.D., of a son.
- ROBERTSON.—On the 24th ult., at the Town's Hospital, Glasgow, the wife of A. Robertson, M.D., of a son.
- GARRINGTON.—On the 25th ult., at St. George's-square, Portsmouth, the wife of Arthur M. Garrington, M.D., of a daughter.
- MONKTON.—On the 26th ult., at Alrewas, Staffordshire, the wife of William Monkton, M.R.C.S., of Brencley, Kent, of a daughter.
- PATERSON.—On April 24th, at Balbeggie, Perthshire, N.B., the wife of Geo. K. H. Paterson, L.R.C.P. Edin., of a daughter.

MARRIAGES.

- ANDERSON—FAUX.—On the 2nd inst., at the Parish Church of St. Peter's, Thetford, in Suffolk, Edward Chas. Anderson, M.R.C.S.E., to Emma, daughter of the late J. Burrell Faux, Esq., of Thetford.

DEATHS.—LONDON.

- SHAW.—On 27th ult., Wm. Shaw, M.R.C.S.E., of Hampstead, aged 57.
- HARRISON.—On the 28th ult., J. Harrison, M.D., of Highgate, aged 83.
- EDMONDS.—On the 1st inst., at 4, Fitzroy-square, London, Harold Charles Edmonds, aged 51 weeks, of spasms glottidis, when apparently in perfect health.

Original Communications.ON THE
**TREATMENT OF ACUTE RHEUMATISM
BY PERMANGANATE OF POTASH.**

A Clinical Lecture delivered at the Adelaide Hospital, April 24, 1866.

By **JAMES F. DUNCAN, M.D. F.C.P., &c.**

PHYSICIAN TO THE ADELAIDE HOSPITAL.

IN my last lecture I explained to you the views that I have been led to form of the nature of gout. I told you that I considered it depended upon imperfect oxidation of the albuminous constituents of the blood arising from impaired nervous energy. That these constituents, when about to be eliminated from the system, underwent a metamorphosis, first into lithic acid, and subsequently into urea by combination with oxygen in different proportions, and that when the process was arrested in its course, the lithic acid accumulated in the circulation in the form of lithate of soda, and gave rise to the peculiar symptoms which constitute the gouty paroxysm. I further mentioned the connexion which I believe exists between this imperfect oxidation of the nitrogenous compounds and impaired assimilation in the digestive system—a connexion which has induced me to resort to the use of hydrochloric acid in the treatment of the disease, and as you may have yourselves observed, on several occasions with very decided benefit.

I proceed to-day to speak of the kindred affection, acute rheumatism, which presents many points of resemblance to gout, but which appears entirely different in its nature, to affect a different class of persons, and to require a different plan of treatment. This disease, as well as the former, seems to depend upon imperfect oxidation of the blood, but the particular constituents which are implicated in the two diseases are perfectly distinct. In gout it is the nitrogenous compounds, in acute rheumatism it is the non-nitrogenous or starchy. These latter seem naturally to pass through the several stages of conversion into sugar, lactic acid, and carbonic acid—changes which depend entirely upon the increasing amount of oxygen which enters into combination with the original hydrocarbon. When the last stage, that of carbonic acid, has been reached, the transmuted starch having fulfilled its office in the economy passes off from the lungs in the act of respiration. I need scarcely remind you that while the nitrogenous articles of food are supposed to contribute to the support of the animal tissues, the carboniferous are believed to be principally engaged in maintaining combustion. It needs no argument to prove that if the series of changes I have detailed do not proceed through their entire course, the imperfectly oxidized products, whether in the form of sugar or of lactic acid, must accumulate in the blood and give rise to disease, constituting in the one case diabetes, and in the other rheumatic fever. That lactic acid, when in excess, is capable of producing all the phenomena of acute rheumatism, including the endocardial deposits on the valves of the heart, has been shown by Dr. Richardson of London, so that no reasonable doubt can remain as to the efficient and proximate cause of the affection; and as I have attempted to show that the imperfect oxidation of the nitrogenous compounds in gout is due to impaired nervous energy, which fails from this circumstance to carry out to completion the chemical changes that take place in health, there is reason to believe that the imperfect oxi-

ation that occurs in acute rheumatism is due to a similar cause, but arising under different circumstances and in a different manner. Rheumatism can generally be traced to an attack of cold disturbing the functions of the body generally, and producing well-marked fever. It would not be difficult to show, from the way in which the various functions are affected, the arrest of the secretions, the change in the temperature of the body, &c., how deeply the nervous system is involved in this state and how much its energy must be depressed.

The view just presented of these two diseases appears to me to be both interesting and important, and sufficient to account for many of the differences which are known to exist between them. For example, while the one prevails chiefly among the upper classes of society, because of the abundance of the nitrogenous compounds contained in animal food of which they partake largely, the other is common among the poor, whose diet consists, to a great extent, of vegetable matter; and while gout is a disease of mature life and even of old age, rheumatism occurs at all ages, not excepting the very young, because all are equally liable to suffer from cold and wet, whereas a long course of indulgence of the appetite seems generally necessary to pave the way for the development of gout.

It may perhaps seem strange that if the views here propounded have any foundation in fact, that the matter has not ere this been made the subject of scientific experiment and reduced to demonstration. But the fact is, that with all our boasted progress of late years, the attempt to penetrate the mysteries of nature is not so easily to be accomplished. Every one acquainted with organic chemistry must be aware of the extreme difficulty of determining the precise constitution of complex substances of this class as compared with those of an inorganic nature. Many different organic compounds have yet the same molecular constitution so far as the number of their constituent atoms is concerned, yet owing to differences in the manner in which these atoms are arranged among themselves, their peculiar properties are totally unlike; and different analysts arranging the constituent elements of these substances according to their individual views will give a different account of their respective constitutions. This difficulty becomes still more remarkable when the subject of our inquiry is a living body and embraces the consideration of vital energy present in the body to be examined and influencing the result. You are all, I dare say, familiar with Claude Bernard's investigations regarding the liver. He first thought that the liver possessed a power of producing sugar out of the blood in its progress to the lungs, and that the sugar thus formed was burnt off in the act of respiration, so that no trace of it could be found in the left ventricle of the heart. He subsequently modified this opinion, so far as to believe that there was in the liver itself a peculiar substance which he named glucogene which had the effect of changing by contact the starchy elements of the blood into dextrine or grape sugar; but the late researches of Dr. Pavy, repeated and confirmed by Dr. Robert Macdonnell of this city, have shown incontestably that what Bernard considered was the natural and normal condition of the liver, was really a post-mortem effect occurring almost at the instant of death, and in all probability the result of the cessation of the energy of life. I mention this to show not only the extreme difficulty of determining questions of this kind, but the strong colour of probability that it gives to the hypothesis which I have here propounded, for if the formation of dextrine be kept in check by the vital force so long as that force is maintained in its full vigour, and if, as appears by these experiments, sugar may be detected in notable quantity in a remarkably short space of time after an animal has been killed, so short in fact as merely to allow of preparations being made for carrying on the investigation, it is extremely probable that anything which materially weakens the nervous energy must favour the production of this very substance which is the preliminary steps to the formation of lactic acid, and which, unless carried forward to

the further development of carbonic acid, must lead to acute rheumatism.

Not that you are to suppose that the correctness of these views is dependent in any sense upon the sugar-producing power of the liver being sustained by the further light which physiology may throw upon this subject. The remarkable point of his investigations was, his shewing that the liver could form sugar out of nitrogenous substances—materials naturally unsuitable for the purpose. But I need scarcely tell you that the more obvious sources of sugar—the articles containing starch which are used as food—find their way into the circulation without passing through the *vena portæ* at all, and consequently without traversing the liver. In whatever way, however, they may be introduced into the blood, they seem to have this useful purpose to serve in the economy, to support the changes occurring in respiration, and to require to be formed into carbonic acid in order to be eliminated from the system.

Let me now very briefly attempt to apply this view of the nature of acute rheumatism to the question of its proper treatment. Setting aside what may be regarded as the treatment of collateral symptoms by special remedies, such as the abatement of pain by the use of narcotics, the plans in ordinary use for the cure of the disorder may be classed under the heads of the antiphlogistic, including bleeding, purgatives, and mercury; the tonic, including the administration of bark, nourishment, and stimulants; the alkaline, including the alkaline carbonates, intended to neutralize the lactic acid; and lastly, agents which contain oxygen in large quantity, and which may be supposed to part with this principle to promote the complete transformation of the lactic acid into carbonic acid. Each of these plans of treatment has its advocates, and no doubt peculiar circumstances in individual cases may render one plan suitable to one case and another to a different one. I am by no means disposed to recommend a routine treatment to any form of disease; on the contrary, I would myself adopt the eclectic plan, and strenuously advise you to do the same. My purpose at present is only to speak very briefly of the last of these plans, which embraces the administration of nitre, of citric acid, and of the remedy you have seen me using of late—the permanganate of potash—a remedy which I am not aware has ever been tried in this disease before, but which I was induced to resort to from a consideration of its chemical constitution. All these substances contain oxygen in large quantity, but the peculiarity of the permanganate is this, that it holds this element in a very loose affinity; so loose, in fact, that it is almost impossible to combine it advantageously with any other substance, as it undergoes decomposition and becomes practically inert. The effects we have seen it produce for so far are these; it cleans the tongue, relieves pain, acts slightly on the bowels, and removes turbidity and fetor from the urine where they have existed. The only drawback to its use has been that several patients have complained of its unpleasant taste. The form in which it has been given has been that of solution of Condé's disinfectant fluid in the proportion of one part to seven of distilled water. Half an ounce of this mixture every second hour for a dose. The strength of this preparation, as given by Neligan, is 9.26 grains to the ounce, while the ordinary solution of the Pharmacopœia is only four grains to the ounce. In classing nitrate of potash among the oxidizing agents, I know that many persons will object to the view thus suggested of its *modus operandi*, and maintain that its beneficial effects are solely due to its property of increasing the secretions from the skin and kidneys; but I think it is not unreasonable to suppose, that among the various chemical changes that take place during its action, some portion of it may be decomposed to answer the purpose in question. Nitrate of potash, however useful in some cases, from its depressing influence on the circulation, is not suited in my judgment to any instances when the vitality is not vigorous. Lemon-juice is, I need scarcely tell you, both palatable and safe, but it is occasionally apt to act on the bowels, as happened in the first of the

cases about to be detailed, for which reason it had to be laid aside after having given temporary relief.

Case 1.—Mrs. E., a strong, healthy-looking woman, aged about 46, a tradesman's wife, was admitted to hospital on March 15th, 1866. Has had attacks of acute rheumatism in an aggravated form on several occasions, with intermediate attacks of rheumatic pains of less intensity. She was a woman of temperate habits, and was about a week ill previous to her admission. Her pains were very acute, affecting the shoulders and both knees, which were greatly swollen and very tender. She was unable to move without assistance. Her skin was bathed in perspiration, of a sour smell and acid reaction to test paper. The urine was highly acid and loaded with lithates. Her pulse was 74; the tongue white and furred. Her heart free from any organic disturbance.

The treatment first resorted to was bark in effervescence, with an excess of alkali, and anodynes in large doses to relieve pain. On the 28th her pupils were contracted from opium, the swelling of her joints less, but the perspiration was still profuse, and of a sour smell. On that day she was ordered half-grain doses of extract of belladonna in pill every second hour, with lemon-juice given freely. The next day her pains were certainly less intense and the swelling diminished, but on the 30th her bowels, which had been somewhat affected on the 29th, were so much purged that the lemon-juice had to be discontinued. On the 31st her pains were nearly as bad as on her admission, and so violent as to render any movement impossible. Her countenance was expressive of the utmost agony and despair; her pulse 92, and small; the perspiration excessive; the urine scanty, highly acid, and of offensive smell. She was then ordered for the first time Condé's fluid in solution.

April 1st: She felt much better, and sat up in bed. Her pain was less, and felt only in knee; countenance much improved; tongue clean and moist; pulse 94; bowels moved twice; took her bottle regularly every second hour, except once, when asleep; sour smell perceptibly diminished; perspired through early part of the night, but not after. Has had no anodyne; attributes the improvement to the medicine.

4th: Had to leave the ward for a short time, in consequence of an operation being performed; was able to walk unsupported, and sit in a chair for some hours.

5th: Perfectly free from pain; appetite good; slept well; no perspiration; sour smell gone; pulse 84.

7th: "Finely." Urine more copious, free from mucus, less acid, and devoid of the heavy smell it previously had.

9th: Quite free from pain; able to walk with perfect ease; tongue clean; pulse 74; urine clear and slightly acid; discharged well.

Case 2.—A. B., æt. 26, a pale, delicate-looking man, was admitted March 21st, having had several severe attacks of acute rheumatism, with an endocardial affection at the base of the heart of some years' standing. The joints principally affected were the wrists, knees, shoulders. There was distinct swelling, but little redness of the parts. The pulse was quick and weak, and his general condition cachectic. After various remedies had been tried, including a combination of quinine, belladonna, opium, and bark in effervescence, with large doses of carbonate of potash, the heart was attacked on March 31st with tenderness, and a bellows murmur at the apex, for which he was put on blue pill and opium.

April 4th: The report states that the bellows murmur had quite disappeared; that his pains were greatly relieved everywhere except in his heart towards the back of the chest, where it is very severe, especially when he attempts to move. With a view to examine his chest I asked him to raise himself up in bed, but it was totally impossible to get him up without assistance, and then he could only be raised a few inches in a standing direction. His look of suffering at the moment was excruciating, and on laying him down again it was some moments before

he could recover his breath so as to speak. Ordered Condy's solution every second hour.

5th: Had a very good night, the best since he came into hospital; cannot complain of pain, as he has none except he makes some considerable exertion; tongue furred; pulse 88; mouth somewhat sore.

6th: No pain to-day except in region of heart, which is greatly diminished; stiffness remains in joints; bowels free; pulse 84; considerable perspiration; sour smell gone; can raise himself in bed without assistance and without suffering.

8th: Able to get up out of bed by himself.

The subsequent progress of this case has not been satisfactory; he got a return of his pains on the 10th, owing, apparently, to exposure of fresh cold, and owing partly to some mistakes in the making up of his medicines and to changes in its composition, from a desire to combine the permanganate with other agents, it did not seem to produce the same effect as at first. The man is still in the hospital, very much better it is true, but not recovered of his ailment. I have again tried the combination of tonics with narcotics, as his strength is so much reduced, and he appears steadily improving. I give you these cases just as they occurred, without attempting to make them prove more than circumstances will warrant. Subsequent experience must determine the point whether this new remedy will have any advantage over older and more familiar ones; but certainly the relief that both these patients obtained at first led me to look upon the permanganate, supposing it to have been the cause of the benefit, as a remedy of no ordinary value in this affection.

Hospital Reports.

[THE present report contains a record of cases under the care of Dr. Lyons in the Hardwicke Hospital, and is chiefly intended to show the obscurity enveloping certain cases of typhoid fever, also the occurrence of a case of "Black Death." Dr. Mapother's case in St. Vincent's Hospital is intended to illustrate the treatment of acute rheumatism by blistering. Mr. Porter's cases in the Meath Hospital are examples of several important surgical operations. We are compelled to overhold other reports to next number.]

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

DR. LYONS'S CLINIQUE.

TYPHOID FEVER: LOW TYPHUS: BLACK DEATH.

THE obscurity which envelops certain cases of Typhoid fever is well exemplified by the following instances of this form of fever occurring in Dr. Lyons's Clinique. He employs the term *Typhic* to define the state of combined asthenia, dusky hue of skin, and general appearances common to extreme cases of typhus and typhoid fevers:—

Typhoid Fever; facies typhosa; purpuric complication; diarrhoea not a prominent symptom; death; profound ulceration of Peyer's patches.—T. F., a girl, aged 10, was admitted in a state of extreme prostration. The duration of her illness previous to admission could not be ascertained with accuracy, but she had been ill for a considerable period. When first seen, at the clinical visit on the morning after admission, she lay on her back, indifferent to all taking place around her; the colour of her face and surface generally was of a dusky and livid hue, and on the chest, neck, and arms she was freely spotted with purpura hæmorrhagica, the spots being of circular form, deep purple tint, one-eighth inch in diameter, and quite unaffected by pressure. Her breathing was embarrassed, and she had much cough, but there was little evidence of abdominal complication of any kind, and at no time while in hospital was diarrhoea a marked feature of the case.

Quinine and stimulants were freely employed, but she became more and more prostrate day by day, and on the fourth day after admission sordes covered the teeth and lips; the bronchial affection had become universal; the thermometer was found to mark 103° in the axilla, the respirations being 48°, and the pulse 132° per minute, and, notwithstanding the most active measures, with abundant stimulation, she died on the afternoon of the same day.

On *post-mortem examination*, the lungs were found to present all the evidence of advanced and most extensive capillary bronchitis, which was obviously the immediate cause of the fatal issue. The heart was healthy; the intestinal tract throughout was much congested, and in the lower third of the ileum, and principally towards the ilio-colic valve, extensive ulceration of the patches of Peyer was observable. Ulceration had proceeded to a considerable depth through the mucous tissues, but had not anywhere laid bare the peritoneum, and irregular circumvallate rings of partially detached typhoid deposit were projected above the surface on many of the patches of Peyer.

On review of the history, symptoms, and pathological anatomy of this case, Dr. Lyons regards it as an example of true typhoid, enteric, or dothionenteric fever, with extreme *typhic* depression, the complication of purpura hæmorrhagica being superadded to the essential febrile state.

Typhoid fever; facies typhosa; frequent relapses; prolonged diarrhoea; typhic depression; recovery.—P. H., æt. 48, carpenter by trade, was admitted in a state of extreme *typhic* depression. He had been ill for nearly a month prior to his reception into hospital, labouring under marked febrile symptoms, diarrhoea, and much consequent depression and debility. When first examined the *typhic* aspect was well marked, the skin was dusky and dirty, but without distinct eruption of any kind; sordes covered the teeth, tongue, lips and eyes; calor mordax was present over the entire surface, and especially on the abdomen; the patient was thirsty, irritable, restless, and worn out with constant diarrhoea. The tongue presented a good example of the state known as *langue perroquet* by the French, being dry, coated with hard, dirty, blackish-brown sordes, and acutely pointed at the tip. The abdomen was hot, full (without tympanitis), and gurgling could be elicited in the right iliac fossa, and the dejecta per anum were copious, of brownish colour, and, in a word, pea-soup like. Tonics, astringents, wine, milk, and farinaceous diet, with poultices to the abdomen, were ordered for the patient, but the pyrexial action continued intense for a lengthened period, with little mitigation of the symptoms above enumerated. On the eighth day after admission (between the thirty-fifth and fortieth day of the disease), the pulse was found to register 104; the respirations 40; and the thermometer 103°, the *typhic* aspect being still unmodified. Milk, with lime-water, well-boiled rice and bread, formed his chief aliment henceforward for weeks in succession, with eight ounces of wine daily. Tonics, astringents, poultices, and other measures were sedulously continued, but much fluctuation was observable in the patient's state. The slightest error in diet was followed by increase or renewal of the abdominal symptoms and diarrhoea; thus, beef-tea having been once given by mistake, much intestinal irritation followed, with copious diarrhoea.

Dr. Lyons, it may be observed, lays it down as a rule to be rigidly enforced during the entire period of the continuance of typhoid or enteric fevers, that the dietary should carefully exclude all animal aliment (with the exception of milk and eggs). From the various forms of farinaceous aliments, such as arrowroot, rice, bread, &c., eggs beaten into custard, milk with or without lime-water, or, more grateful still, effervescing carraza water for private patients, he states that an abundant, nutritious, and unirritating dietary can be selected. That beef-tea or any other form of animal aliment has a special irritant action on the intestinal mucous membrane experience has fully satisfied him. Animal aliment in any shape, in Dr.

Lyons' opinion, promotes, if it does not induce, the action of ulceration in the surcharged solitary glands and patches of Peyer. The irritation thus excited in the intestinal canal diminishes the probability of elimination of the typhoid matter from the glands being accomplished without ulcerative action; and the patient is thus deprived of his best chance of that most favourable of all the possible modes of termination of the intestinal lesion of enteric fever—namely, that by which the typhoid matter is slowly softened and disintegrated, and gradually exuded from the glands and patches of Peyer by the ever-acting vermicular constriction of the circular and longitudinal fibres of the intestinal muscles.

In the case of the patient under consideration, frequent alternations of pyrexial action were observed, with a frequent renewal of intestinal irritation and diarrhoea. Thus on about the fortieth day of the disease, the pulse was 104, respiration 40, and much abdominal irritation and diarrhoea were present. For eight days subsequently the pulse rose gradually to 128, and again gradually declined in the eight subsequent days to 92. After a further interval of five days it again rose to 128, and it was not until between the sixty-fifth and seventieth day of the disease that gradual and, as it proved, permanent convalescence commenced to be established. The total duration of this case was about eighty days. For weeks subsequent to the period of complete defervescence, as manifested by clean tongue, clear and cool skin, and absence of all intestinal irritation or tendency to diarrhoea, Dr. Lyons enforced a rigid adherence to the strictly farinaceous regimen, with milk and eggs. He is of opinion that in many cases of enteric fever a period of fully three months must be allowed to pass over from the date of the commencement of the disease before the patient can be considered safe, and the intestine restored to a healthy state.

Whether after enteric fever the mucous membrane of the intestine is ever restored to a condition of integrity in structure and function identical with that which prevailed prior to the invasion of the disease is, he thinks, more than doubtful. If ulcerative action supervene on the elimination of the typhoid deposit, and that the patient survives, a cicatrix takes the place of the gland or patch, as well shown by the researches of Drs. Lyons and Aitken. If elimination takes place without ulceration by the gradual disintegration of the typhoid matter, which thus becomes gradually exuded from the glands by vermicular contraction of the intestines, the glands themselves appear to undergo a process of wasting and shrivelling. A minute honey-combed appearance remains, and dark central pigimentary dotting will be observable in the minute cup-shaped depressions which occupy the sites of the former gland-follicles. The records of the following case offer an opportunity of studying the state of the glands in a case of typhoid or enteric fever, in which death ensued from acute pleuritis with excessive effusion consequent on exposure to violent cold drafts at a very advanced period of the patient's convalescence from the fever and its intestinal complications. It is, further, an example of the partial and fallacious convalescence which in certain instances takes place after the first attack of the fever, which may present obscure and insignificant symptoms, and it shows how these cases require to be looked upon as a whole, and how liable they are to misinterpretation in regard to their nature and treatment, especially if, in the different stages, they should fall, as frequently happens, into different hands. After the full development of Dr. Lyons's views just given the case requires but brief comment.

Typhoid or enteric fever; first stage of short duration and insignificant symptoms; relapses; typhic prostration; convalescence; death by acute pleuritis.—J.M., aged 22, admitted with comparatively mild pyrexia, and left hospital apparently convalescent on the eighth day after his reception. After an interval of twenty-six days he was readmitted with profound typhic depression, some abdominal disturbance, and occasional diarrhoea. For a considerable period this patient took twelve ounces of wine daily, and finally

convalescence from the febrile state became fairly established, when, during very violent and stormy weather, he was incautiously left exposed to the sweeping down draft of an open window, pleuritis set in with most marked symptoms of sudden depression, copious effusion rapidly followed in the left pleural cavity, the pulse rose to 150, and death took place on about the forty-eighth day from the date of the first attack.

On post-mortem examination the left lung was found compressed to an extreme degree by pleural effusion. The ileum intestine exhibited a state of parts familiar to all pathological anatomists, as that in which elimination of typhoid deposit has taken place without ulceration. The solitary glands and patches of Peyer showed a superficial minute honey-combed appearance, thickly studded with black dots, constituting the *shaved-beard* appearance of authors. In this case, and a somewhat analogous one of true typhus, occurring at the same time, and in which, from an identical cause, effusion to like extent, and on the same side of the chest, proved fatal, the state of depression of the patient precluded the idea of paracentesis thoracis.

Typhus Siderans; Black Typhus; Black Death; Febris Nigra; Death in Sixteen Hours—In illustration of the tendency to profound depression of the vital powers occasionally presented in the current fever, Dr. Lyons observed on the recent occurrence of the following case, the rapidly fatal issue and appalling symptoms of which are worthy of record:—

The patient, a female, aged 22, unmarried, in the prime of youth, vigour, and beauty, was attacked with chills, headache, and sick stomach between ten and eleven a.m., having felt so well on the previous day that nothing but the state of the weather prevented her from taking exercise on horse-back. She continued unwell through the day, but the symptoms were not such as to excite uneasiness, and medical aid was not sought until the lapse of some hours. At 9.30 p.m. Dr. Lyons saw her for the first time. She was then quite pulseless, but perfectly conscious, the eyes were much congested, the tongue furred, the lips livid, while the face, forehead, neck, trunk, arms, hands, and backs of fingers were covered with irregularly-shaped dark purplish patches, from the one-eighth of an inch to a quarter and a half inch in diameter, and on the back some of the patches were an inch and a half in long diameter, and half to one inch across, and of angular outline. The lower extremities presented at this period several spots of similar kind, with a general dusky purplish discoloration of the intervening skin. The heart's action was audible to the stethoscope, but very faintly, and beat about 130 per minute. The feet were cold, and pains in the legs, back, and shoulders, were much complained of, with an intolerable sense of weariness and distress, and epigastric anxiety. Headache, as well as sickness of stomach, had quite disappeared, but the patient, who spoke with a strong and clear voice, and moved in the bed without difficulty, said she would gladly take the headache and other symptoms back in exchange for the sense of distress and depression, and the wearying aching of the whole frame, and the most anxious longings for sleep. Active measures were at once put in operation to rally the system: hot stupes were applied to the feet, mustard poultices to the calves of the legs and over the heart and stomach, while hot brandy punch, brandy beaten up with the yolk of egg, chloric ether, and aromatic spirits of ammonia, were given in quick succession, were readily taken, and well retained. Some slight attempt at rallying followed these measures, the patient spoke with distinctness, and made inquiries respecting the state and comforts of her friends. But about one p.m. she began to waver, consciousness gradually failed, the purple spots grew almost visibly larger, and of darker hue, and when again summoned to see her at three a.m. Dr. Lyons found the lips black blue, the face and neck covered with an uniform sheet of purplish black discoloration; the trunk presented numerous large patches of

similar colour; the arms on front and back exhibited an almost continuous expanse of the same hue; and on the anterior as well as the posterior aspect, the lower extremities showed one unbroken mass of blackish purple discoloration; the soles of the feet and plantar aspect of the toes were the parts least affected with this deadly tint. The heart's action was all but imperceptible, the respiration hurried in the extreme, and broncho-tracheal effusion was rapidly advancing. Death ensued in about twenty minutes, being at one interval less than fifteen hours from the period when any noticeable departure from health had been first observed. The discoloration continued unaltered after death. Dr. Lyons regards this case as an example of extreme typhic prostration, with the associated condition of rapidly developed purpura hæmorrhagica, affecting so far as was observable, the cutaneous system of capillaries. No hæmorrhage from the nose, gums, eyes, or other parts took place, and the circumstances of the case did not admit of post-mortem examination. Dr. Lyons observes on the importance of most carefully noting the appearances offered by the skin in all cases of fever, and the necessity for early stimulation and other appropriate remedial measures should any form of petechial eruption make its appearance. Dr. Lyons recommends large doses of the combined phosphates of strychnia and quina, with the boldest stimulation from the outset, when any such appearances present themselves.

Dr. Lyons is engaged on observations connected with the action of a combination of chloric acid and quinine in low febrile states, and trusts to be able to procure the manufacture of a chemically stable chlorate of quinine. At a future day we shall report the result of his inquiries.

Dr. Lyons will feel obliged for notes of any cases of "*Febris Nigra*" recently observed by Irish physicians.

ST. VINCENT'S HOSPITAL.

ACUTE RHEUMATISM TREATED BY BLISTERING.

(Under the care of Dr. MAPOTHER.)

A. B., ætat. 28, and married, by occupation a hair-dresser, a native of and a resident in Dublin, was admitted to St. Vincent's Hospital on the 20th of March, 1866, under the care of Dr. Mapother.

Two and a half years previously he suffered from an attack of acute rheumatism, in which both wrists and the right knee were affected, and there was a slight endocardial murmur. At that time he was salivated. He recovered, and ever since has had a delicate chest.

At the present date (March 20, 1866), he suffers from acute rheumatism, all the leading symptoms of which are well developed. Now, as in the former attack, both wrists and the right knee are affected; but, unlike the former attack, there is now no peculiar cardiac murmur; the action of the heart is, however, very quick.

The treatment adopted in this case may be described as special. He got powders composed of nitre and Dover's powder, with antiphlogistic regimen; but the point to which Dr. Mapother directed attention was the local treatment by blistering. In four hours after the first application of blisters to the affected joints, the patient experienced the greatest relief, and continued to be free, to a great extent, from pain, up to the time of my first visit (21st of March).

At that time he had a very pinched anxious expression of countenance.

24th: I again saw this case. He had complained of pain in the præcordial region on drawing his breath; no friction sound could be detected, but he had had a blister put over the heart yesterday, and since then he has been taking the following powders:—

R. Calomelanos, gr. iij.

Pulv. Jacobi, gr. iij.

Nitr. potassæ, gr. v. M.

Ft. pulvis, sumat talem. ter indies.

28th: I saw him a third time. No friction sound perceptible; the pain has disappeared, save on drawing breath, when it is felt, though much less than at the time of my last visit. Meanwhile he has been salivated; but he no longer takes the powders prescribed previous to my last visit.

April 4th: I saw him again to-day, and was informed that since my last visit considerable roughness in the second sound was discovered. His pulse is now jerking, dirotous, and visible. He has no pain, except in the act of coughing, and then it is felt equally all over the body. He has quite got rid of the rheumatic pains. The salivation, noted at last visit, has been followed by mercurial diarrhœa, in consequence of which the mercurial treatment was stopped, and starch and opium enemata ordered; also a cough mixture, containing tincture of hyosciamus and hydrocyanic acid.

18th: He has had occasional attacks of dyspnœa referable to the sternum, and accompanied with fear of impending sinking. These attacks were relieved at once by smoking the *datura tatula*, the effect of which was perceptible in five minutes. This agent, however, lost its efficacy after two or three occasions. These sudden attacks had much the character of angina pectoris, which is interesting in connexion with the evidence of inflammatory disease of the aorta, for the two conditions have been regarded by Sir D. Corrigan as cause and effect.

The advantages of the blister treatment, so far as regards the relief of pain, were most striking in this case. Dr. Mapother remarked that as Dr. Garrod had proved that blister serum in gouty cases contained the specific poison of that disease, his treatment acted in this, by abstracting from the blood the poison of rheumatism which would appear to be specially determined to the joints and fibrous tissue

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.

CASES UNDER THE CARE OF MR. PORTER,

SENIOR SURGEON TO THE HOSPITAL.

[Reported by ARTHUR WYNNE FOOT, M.D.]

(Continued from page 451.)

VARICOCELE: SUBCUTANEOUS LIGATURE OF THE SPERMATIC VEINS BY RICORD'S OPERATION.

Case 12.—George Fay, 32 years of age, a servant, unmarried, in height six feet two inches, was admitted with varicose veins in the left lower extremity and left side of the scrotum. Since he was ten years old he had remarked a prominence and distension of these veins; but the occurrence of varicose ulcers on the leg within the last three years, accompanied with a weak dragging pain along the left spermatic cord, in the groin, and in the lower part of his back, particularly after much muscular exertion, made him very anxious for permanent relief. Seven small oval ulcers were discovered on the left leg, which was swollen, purple, and glazed; the integument of the left side of the scrotum was very superabundant; the spermatic veins were numerous, large, and tortuous, particularly when he stood up. This affection had produced the usual depression of mind with which it is so constantly associated. The hair having been removed from the pubis, the varicose spermatic veins were isolated from the cord and a loop of iron wire passed behind them, a second loop of wire was then passed in front of them through the same orifices as the first, the free extremity of each wire being passed through the loop of the other, the wires were then drawn in opposite directions until the loops had almost entered the scrotum. The "retracting guides," devised by Mr. Tuffnell, and figured in the thirty-second volume of the *Dublin Quarterly Journal*, were then applied as he directs, two portions of wire, each doubled in the middle as closely as possible, were passed through either loop and drawn to its centre. The "main wires" were then forcibly drawn

upon until the spermatic vessels were completely strangulated, their ends were kept tensely strained by being twisted round a piece of spring wire bent into an arc. The operation was not followed by very severe pain or by supuration in the scrotum. The wires were removed in four days.

At the present time, a fortnight after the operation, the external wound is healed, a small hard knot marks the place of ligature, the skin of the scrotum is much less relaxed, and the veins below the ligature do not become distended as they did before. His mental condition and spirits show a corresponding improvement. Mr. Porter remarked upon the predisposing effect which this man's stature, taken in connexion with the anatomical relations of the spermatic veins, had in producing the disease; upon the disproportion between the mental distress and the actual disease which is almost always observed in varicocele, and commended highly Mr. Tufnell's "retracting guides," by which the surgeon is able to withdraw the ligature at any time without waiting for it to come away by ulceration through the vessels.

EPULIS—REMOVAL OF THE TUMOUR WITH THE CONTIGUOUS TEETH AND SUBJACENT BONE.

Case 13.—Catherine Austin, 36 years of age, was admitted with an epulis the size of a walnut, growing from the labial surface of the alveolar process of the left side of the lower jaw, corresponding to the insertion of the incisor and canine teeth. The tumour had been three years growing. The right central incisor and the left canine having been extracted, the alveolar process was divided vertically through the sockets of these teeth with a Heys' saw, and with a bone-nippers a square portion of bone, corresponding to the attachment of the tumour, was removed. The wound was plugged with a piece of lint. The structure of the epulis was mainly fibrous, as is generally the case with these innocent locally recurrent tumours, it was, as usually, connected at its base with the periosteum of the very vascular adjacent alveoli.

BILATERAL TALIPES VARUS—DIVISION OF THE TENDO-ACHILLIS AND TENDONS OF THE TIBIALIS ANTICUS ON EITHER SIDE.

Case 14.—A boy, four months old, with deformed feet, was the subject of the operation. The tibialis anticus was divided on either side, subcutaneously; the skin over the tendon having been incised, a tenotomy knife was introduced flatwise, and the edge then turned downwards upon the tendon, which was put on the stretch, and cut through from above downwards; a pad of lint was put over the spot, and the corresponding tendon on the other foot divided in a similar manner. The child having been then turned on its face, the heel was bent upwards; the relaxed skin pinched up; the knife passed flatwise, superficial to the tendo-Achilles, and the tendon then divided from above downwards; pads of lint, and bandages which strongly abducted the feet, were then applied. The after-treatment is being carried out with suitable apparatus to restore the feet to their proper position.

DEFORMITY OF THE LOWER LIP AND CHIN FROM THE CICATRIX OF A CHANCRE, WHICH HAD BEEN TREATED WITH CAUSTICS FOR ITS REMOVAL: RYND'S OPERATION.

Case 15.—James Ryan, 34 years of age, was operated on with a view to rectify a great disfigurement of his appearance from the loss of his lower lip and exposure of his teeth and gums, and to prevent the constant loss of saliva and of food during mastication from his mouth.

The operation devised by Mr. Rynd, and described by him in the thirty-second vol. of the *Dublin Quarterly Journal*, was performed. A knife was passed through the mucous membrane of the lower lip from one canine tooth to the other; a second incision separated all the soft parts of the chin from the body of the bone as far down as its lower margin. The chin, now movable from having been

loosened from its attachments to the bone, was drawn upwards by strips of adhesive plaster brought from under the chin and made to adhere to the zygoma on either side. The operation, which was performed exactly in the manner indicated by Mr. Rynd, resulted in the approximation of the new lower lip to the upper one and the consequent closure of the mouth, which obviated the distressing effects of the destruction of his original lip.

Proceedings of Societies.

HARVEIAN SOCIETY OF LONDON.

APRIL 19, 1866.

DR. TYLER SMITH, President.

DR. RICHARDSON'S LOCAL ANÆSTHESIA.

DR. C. DRYSDALE said that he had found the apparatus invented by Dr. Richardson for freezing the tissues perfectly successful in causing complete anæsthesia in several operations performed by Mr. Dunn, at the Farringdon Dispensary. Among these cases were the incision of a carbuncle, the opening of abscesses, the excision of warts from the vulva and perineum of a young woman, and the touching of large secondary syphilitic ulcers with strong nitric acid, &c. In none of these cases was any pain felt.

Mr. J. B. BROWN, jr., thought that a mixture of chloroform with other ingredients, which he had lately shown to the Obstetrical Society, obviated the danger of death from chloroform, and thus rendered Dr. Richardson's apparatus not of such prime importance. He did not think that the latter apparatus would succeed in many cases of tooth extraction, as the cold would, he believed, prove unbearable in such cases. It would be dangerous too, he thought, in ovariectomy after the external incision had been made. As to the reported case of Cæsarean section, it could not be said to have succeeded, as the child died.

Dr. CAMPS thought there was no proof that there was great pain felt after the incision in the skin had been made in cases of ovariectomy, and he was not convinced that evil would arise from using Dr. Richardson's apparatus in such cases. He thought that there was no doubt that the case of Cæsarean section reported must be considered a complete success.

A paper was read

ON SOME FURTHER REMARKS UPON EMBOLIA, AS AFFECTING THE GREAT VESSELS OF THE HEART.

Dr. STEWART, after reading an abstract of his former paper, read before the Society (Jan. 19, 1865), described the various forms of fibrinous clots or concretions found in the heart after death, added, in the words of Dr. Richardson, that the proofs of a post-mortem clot, or polypus,

I.—Were its position, upon the upper surface of a red coagulum, and its being easily washed away by a gentle stream of water.

II.—Of an *ante-mortem* clot or formation.

a.—By its filling a cavity.

b.—Its being grooved externally by a current of blood, or bored by a current through its centre.

c.—Its being firmly adherent by a mechanical or organic tie to the walls of the heart or vessel.

d.—Its structure being laminated, or containing in its centre broken up fibrine.

e.—Lastly, its being deeply indented by the surrounding structures.

He then described the theories advanced by Dr. Richardson, Mr. Lister, and M. Schmidt, as to the causes of coagulation of the blood and hyperinosis; to the discovery of "fat" or "fatty matter" in the blood by Vauquelin and others; adding the results of some investigations of his own upon the blood of a gentleman (still alive) *æt.* 36, suffering from polysarca and fatty degeneration of the heart, and also upon the blood of a prize ox and a prize

sheep; in all of which he found oil globules mixed with blood discs, and the cases of the two latter blood discs undergoing a degeneration from fat or oil, were found. Dr. S. mentioned the latter fact as requiring confirmation, but a subject which he thought will amply repay any time and trouble devoted to it. He thought it would be found in cases of polysarcoma as a prolific cause of embolia. Atheromatous deposits in the vessels themselves, and in the heart and its valves, were commented upon as a cause, with Lister's views thereon. "Meissner's Report upon Embolia;" Lancereaux's, Panum's, Virchow's, Lebert's, and Henry Lee's researches were alluded to, also the more recent treatise of Mr. Callender.

Dr. Stewart concluded by quoting cases of his own, of Drs. Gairdner, H. Davies, Richardson, and Draper Macindar, Mr. E. H. Roc, and lastly one still under observation in his own practice.

Dr. DRYSDALE said he was quite ready to admit that embolia were to be found in the smaller vessels, such as the femorals, the middle cerebral arteries, or the branches of the pulmonary artery; but he could not help remaining in doubt as to the occurrences of such large embolia as those which would occlude the aorta and pulmonary artery, and thus cause sudden death, as described by the author of the paper. He thought these clots observed were post-mortem formations.

Mr. TIMES related a case where sudden death had taken place, and on making a post-mortem examination a large clot was found in the pulmonary artery, which he believed had caused suffocation.

The PRESIDENT said that midwifery had furnished more facts towards the elucidation of this question than either medicine or surgery. The circulation was sometimes very languid after delivery, and phlegmasia dolens might collect. In some cases *débris* from the femoral and other veins might pass up through the left side of the heart and there form a nucleus for a secondary embol or plug. Abscesses are found in the lung from this cause. On the other side of the heart the causes were well authenticated; there was fringed state of the valves, and coagula might take place round these and be propelled into the brain, causing apoplexy or inflammation of the brain; inflammation when small portions entered, and apoplexy when larger portions entered. Arteritis might occur in the extremities in the puerperal state. A woman with disease of the heart and loud murmur had obliteration of the femoral arteries in both limbs; both of the limbs sloughed and dropped off. He believed that there was arteritis, since there was violent pain in the limbs.

Dr. CAMPS said that wherever there was an irregular surface fissures would be deposited. He could not think that all the cases described by Dr. Stewart were merely due to post-mortem changes in the body. It was of course difficult to see what practical result would be attained to, even were the diagnosis made of an embol existing in the heart.

Dr. STEWART, in reply, said that Dr. Richardson had, he thought, clearly pointed out the marks by which we might recognize whether a plug was found previous or subsequent to death. No connective tissue could be found after death.

WESTERN MEDICAL AND SURGICAL SOCIETY.

FRIDAY, APRIL 6TH, 1866.

GEORGE POLLOCK, Esq., President, in the Chair.

THE PATHOLOGY OF SYPHILIS.

By JAMES R. LANE, Esq.

The paper gave an account of the chief doctrines concerning syphilis the last fifteen years; and the remarks of the author were chiefly made to simplify much that had of late been confusedly written on the subject. Mr. J. Lane gave a brief history of the doctrine of Ricord, and of the consequent development of the theory of the quality of the venereal poison which had of late met with

acceptance in various quarters. There were still, however, he stated, many good authorities, upon whose side he enrolled himself, not disposed to accept the sweeping distinctions which had been recently made between the different kinds of venereal sores; but who held to the older notion that all those contagious ulcers had their origin in one and the same poison. Whilst fully admitting the practical value of distinguishing between the indurated or infecting, and the soft or non-infecting sore, he denied that the rule was absolute, or that it was possible to predict with certainty of any given sore, that it would or would not be followed by secondary symptoms. There was no certain proof of the infecting nature of the sore, but the fact of infection itself. He firmly believed in the occasional occurrence of constitutional infection from the non-indurated sore.

His view was, that the presence of the induration greatly favoured the absorption of the poison, and that the suppurative or ulcerative action in the sore went far to prevent it, but did not suffice to prevent it in all cases. The fact that the soft sore might occasionally cause constitutional infection, told, he thought, in the strongest possible manner against the double virus theory.

Alluding to the period of incubation, said to precede the appearance of the indurated sore, he stated his belief that no such period was observable in a large proportion of cases, but that they were frequently developed like the soft sore, in the form of a pustule in the first instance, in a very brief period after contagion, and that the pustule afterwards became invested with the character of the indurated sore. There were, however, cases, not very rare, in which an unmistakable period of incubation, of from eight or nine days to three or four weeks, was observed; and they were probably examples of contagion from secondary syphilitic affection, such as mucous tubercles. It had now been conclusively shown that certain secondary affections were contagious, and it had been very constantly observed that the local effect which they produced did not become manifest till after a lapse of time, such as just mentioned.

Mr. Lane then discussed the question of the inoculability of the indurated sore, on the individual bearing it, or upon another syphilitic patient, which had been strongly denied. There was undoubtedly considerable difficulty in successfully inoculating with the scanty serous discharge peculiar to the indurated sore; but if the sore made were to suppurate by some slight artificial irritation, he believed the secretion would be found to be inoculable in the majority of cases. He stated his own positive experience in favour of this view, and that on a larger scale of Drs. Sperin, Boeck, Bidentkap, and others who had long practised syphilisation. On the limbs or trunk the matter produced by inoculation with the matter of a hard sore was identical in appearance with that produced in the same way from the soft sore, and thus afforded further confirmation of the view that there was no essential or generic difference between the two kinds of ulcer.

He was well aware that the theory of the mixed chancre would be adduced to explain the various anomalies in the double virus theory, and no doubt it did so. But the evidence in favour of the mixed chancre (a sore that combined the characteristics of the two kinds of sore, and which resulted from the implantation of the two supposed distinct poisons on the same spot) was of the slenderest possible character, and barely deserved elevation to the level of pure hypothesis. He rejected it as a myth, sprung into existence owing to the various difficulties of the double virus theory.

Mr. Lane said he had endeavoured to give expression in the paper to the opinions, which he entertained, that many of the recent researches on the subject of syphilis had not been advanced in the right direction, and that there had been too great a disposition to dogmatise and reduce positive laws from a one-sided examination of facts. There was much to be learned, but there was also much to be unlearned; and the doctrines of twenty years ago were not yet so completely revolutionised as some modern authors would have us believe.

Foreign Medical Literature.

CASE OF BRIGHT'S DISEASE, RUNNING A LATENT COURSE UNTIL URÆMIA SET IN.

Communicated by Dr. ERNST ODMANSSON.

Translated from the *Hygica* for November 1865, p. 433,

By WILLIAM DANIEL MOORE, M.D. Dub., M.R.I.A.,

HONORARY FELLOW OF THE SWEDISH SOCIETY OF PHYSICIANS, OF THE NORWEGIAN MEDICAL SOCIETY, AND OF THE ROYAL MEDICAL SOCIETY OF COPENHAGEN; EXAMINER IN MATERIA MEDICA AND MEDICAL JURISPRUDENCE IN THE QUEEN'S UNIVERSITY IN IRELAND.

CARLSSON, aged 23 years, was admitted into the Garrison Hospital on the 21st April, 1865. The only information which could be obtained from those about him was, that he had been ill for a week, and that during conveyance to hospital he had an epileptiform attack. On arriving there he was insensible, his face was pale, his pupils were widely dilated and were almost insensible to light, his pulse was quick, his respiration slow and moaning. He was ordered to be cupped on the back of the neck, to have a bladder of ice to the head, and to get a purgative enema. During the course of the first day convulsive attacks occurred twice in the hour. Towards evening they gradually diminished in frequency; the last took place in the forenoon of the following day (the 22nd). At the same time the pupils began to contract, the face acquired a redder colour, but the comatose condition continued the whole day. On the morning of the 23rd he lay in a deep and tranquil sleep, consciousness returned gradually in the course of the day. The urine, which during the preceding days was passed in small quantities in the bed, began to diminish in amount. On the 24th the patient was quite clear. Of his previous history he gave the following account:—"As a child he had been healthy until his thirteenth year, when he was for some time under treatment in the Seraphim Hospital for dropsy, which had attacked him in a cold and damp residence." In the following year he had for three weeks ague without dropsy. From this time his health was excellent until his last illness." On questioning him more closely, how-pass water during the night. A week ago he began to be ever, he admitted that he had latterly suffered occasionally from headache, and that the flow of urine had been more copious than before, though he had not been obliged to annoy with headache and a mist before his eyes. The power of vision diminished gradually until he became totally blind. The day before his admission into hospital he lost consciousness.

Status præsens on the 24th. The patient is of a strong muscular frame, and is in good condition. His skin is soft and moist. He exhibits no dropsical symptoms, no pain nor tenderness in the region of the kidney. Slight redness of the cheeks, the pupils large and little movable, power of vision considerably diminished. He thinks he has a thick gauze before his eyes and sees black spots floating before them. Severe headache in the frontal region. The impulse of the apex of the heart in the fifth intercostal space is situated directly in and outside the parasternal line; a slight systolic vibration is perceptible throughout the præcordial region. The cardiac dulness occupies a space of two square inches in the usual situation. The sounds are pure, loud, and resonant, particularly the second, which is strongly accented. Pulse from 80 to 84 in the minute, small but hard. The urine passed during the last twenty-four hours amounted to about three quarts. It is of a light straw colour, specific gravity 1.010, it contains a large amount of albumen and only a trace of uroglaucin. It deposits a finely granular sediment, exhibiting a number of small,

brittle, waxlike tube-casts, of medium thickness, naked or sparingly studded with nuclei and fat globules, with a few dark granular nucleated casts, and some waxlike or fat granule, containing renal cells, but no hyaline casts or blood-corpuseles.

He wishes for food. A natural motion in the morning. The lungs, liver, and spleen present no remarkable change.

The patient rapidly regained his strength, and in a few days was again upon his legs. The daily amount of urine increased to nearly four quarts, and continued at that point, with the exception of a short time, when it was still higher, up to his last illness. Its specific gravity varied between 1.007 and 1.009. The amount of albumen continued as great, but the sediment diminished so that we could sometimes look for morphic elements from the kidneys; those which were found were of the nature above described. When the patient was quiet, the action of the heart was even and calm, the pulse was from 72 to 74 in the minute, and was small but tense. On greater exertion, especially in the open air, the heart's action increased considerably. He then usually got headache; not unfrequently, particularly towards the close of his illness, he suffered also during the night or on awaking in the morning from pain in the head. In other respects he felt perfectly well. His appetite was particularly good, the bowels were regular, the skin was moist, sweating on any bodily exercise. He would have presented a picture of good health, were it not that his pupils continued rather large and fixed, giving a peculiar expression to the countenance.

The power of vision improved only slowly. The fundus oculi was examined several times with the ophthalmoscope. On the first occasion (May 7) both pupils were found to present a certain gelatinous, greyish, indistinctly circumscribed appearance. Around this, and as far as could be seen, appeared a number of larger and smaller, irregularly-shaped milk-white spots, lying now between, now directly in front of the larger veins. In the latter case the vessels were swollen outside the spots; within these they were of smaller calibre. At the same time some small, streaky extravasations of blood of a deep red colour were observed. From later investigations it appeared that the white spots gradually lost their defined contour, colour, and opacity. Finally, most of them wholly disappeared. On the last examination (on the 2nd of June) only a very few could be discovered in the anterior parts of the retinas. The contours of the pupils became gradually more distinct—more so, however, in the right than in the left eye, in which latter the power of vision was and continued rather worse than in the right. Occasionally some fresh extravasations were observed, of which a couple were in front of the white spots; they soon disappeared again. About the 20th of May the patient could read large type; fourteen days later he could read even small type. The distance of distinct vision had, according to the patient's statement, been shorter than before, while he constantly seemed to see the object through a mist, which, nevertheless, gradually became thinner.

During the first month no medical treatment was employed. On the 27th of May the use of tannin (from 15 to 20 grains per diem) was commenced with daily packing after taking elder-tea. This treatment did not disagree with him, but as the desired object, by increased excretion from the skin somewhat to limit the diuresis and thus the considerable loss of albumen, was not attained, inasmuch as the quantity of urine, in spite of copious perspiration, not only did not diminish, but, on the contrary, increased to about four and a half quarts, while the albuminuria continued as great, the packing was dispensed with on the 5th of June. The tannic acid was continued for some time longer, but, as might have been expected, without the least effect in diminishing the albuminuria.

From the 15th of July to the evening before his death I did not see the patient. He had been well until the 21st of July, when for some days he suffered from vomiting. For the last two days of July he had several loose motions, which, during the night preceding the 1st of

* The journal of the hospital of the time records him as suffering from quartan ague, and states that he was dismissed cured.

August, were followed by vomiting. At the same time it was observed that the quantity of urine was somewhat diminished, while there was considerable tenderness in the epigastrium. He was now treated with leeching to the pit of the stomach, wet bandages, and one-fifth of a grain of morphia three times a day. The vomiting soon ceased, but nausea continued. The tenderness, which on the 2nd had extended over the whole abdomen, subsequently diminished gradually. On the day just mentioned the patient could not himself empty his bladder; on the following day the urine passed readily. Meanwhile the daily amount of urine diminished, and on the 5th was only three pints. On the 6th the power of vision began somewhat to lessen. During the night a convulsive attack occurred; another followed next morning. The quantity of urine had during the last twenty-four hours fallen to a little more than a pint. He was treated with an icebag to the head, warm bath with packing, which was not, however, followed by perspiration, and a purgative enema. A fresh seizure took place at five o'clock in the afternoon. On our going round immediately after, he lay in deep coma; his face was pale, the pupils were dilated, the pulse was quick, fuller, but weaker than before. In the course of the night the respiration became slow and stertorous; orthopnea set in, and the patient died at four o'clock on the morning of the 8th August.

Dissection thirty-one hours after death.—The length of the body is somewhat above the average. The subcutaneous cellular tissue is rich in fat. The muscular system is strong and healthy. There is general, but slight cadaveric rigidity.

The *sinuses in the dura mater* contain more or less firmly coagulated, with some fluid blood. The soft membranes of the brain are moderately congested. Both the grey and the white cerebral substance are exsanguine. The latter presents a putty-like appearance, and exhibits in general a shining, moist surface of section; here and there this is drier. The lateral ventricles contain some teaspoonfuls of a rather turbid fluid, inclining to a red colour. The fornix and tenia semicirculares, with the adjoining portions of the corpora striata and thalami optici, are macerated and pale. The cerebellum is otherwise in the same state as the cerebrum, but is drier. On cutting through the medulla oblongata, the surfaces of section are covered with a coherent layer of a thin clear fluid; this exudes most abundantly from the anterior parts. In the middle of this are seen some dilated veins with a few small point-like hæmorrhages.

The *pericardium* contains about an ounce of a clear, slightly reddish serum. The heart is large. In all its cavities are found coagula both of blood and fibrin; the valves are healthy. The endocardium is slightly tinged with the colouring matter of the blood. The columnæ carneæ in the left ventricle are long and thick. The length of the left ventricle, reckoning from the middle of the margin of attachment of the right aortic valve, is 10½ centimètres (4.1339"). The thickness of the wall in the middle of the ventricle is from 16 to 17 mm. (17 mm. = .66929"). The muscular structure is firm, pale, rather dry, and presents a slightly waxy lustre. The thickness of the wall of the right ventricle is at most 6 mm. (.23622").

Both *lungs* are free from adhesions, but collapse only slightly. The anterior edges are moderately congested, and exhibit a not inconsiderable interstitial, with a slight vesicular, emphysema. The posterior parts are congested, contain but little air, and are of loose consistence; on pressure, in addition to blood, a more or less frothy, thin, fluid exudes.

The *peritoneum* is in general pale, in some scattered spots it is discoloured with an inconsiderable venous congestion. In the middle portion of the duodenum, as well as on the surface of the liver and spleen, a number of small papillary vegetations of connective tissue exhibit themselves, in the last-named organ in connexion with a general thickening of the capsule. The spleen is fourteen

centimètres (a little more than five and a half inches) in length, and is of loose consistence; the surface of section is of a more uniformly light-red colour; the Malpighian bodies are large. The kidneys are small; their capsules separate with tolerable ease; their surface is everywhere finely granular, in general pale, but exhibiting here and there large stellulae Verheyinii, and in some places point-like extravasations; the cortical substance is considerably reduced, here and there it is only 2 mm. (.07874") in thickness, in some parts it has a pale, homogeneous, lardaceous appearance, while in other (usually rather thicker) parts the fasciculi and intervening portions can be distinguished now by the veins running in the latter, again by the light-yellowish colour of these intervening portions; the pyramids are large, coarsely streaked with red. The liver is flaccid; its surface of section is of a uniform reddish-brown colour; the acini are not very distinct, but are of ordinary size. The gall bladder is half filled with light-yellow thin bile. The mucous membrane of the stomach throughout its whole fundus is of a light slate colour, and is somewhat softened. The intestinal mucous membrane is pale. The urinary bladder is filled with almost clear urine.

In the *eyes* nothing morbid can be discovered. The retinae separate easily from the chorioideæ, carrying with them small groups of the pigment cells of the latter; the larger veins are tolerably congested; the retinae are otherwise, throughout their whole extent, of an uniform transparency, without a trace of any spots.

On microscopical examination of the retinae, adventitious scattered fat-granules were met with on the outer parts of the stroma of connective tissue, as well as on those of the smaller arteries, in the former situation a few pigment granules were also found; sometimes a coloured cell or nucleus was seen in both granular layers; in many, perhaps in most preparations, not the slightest change could be observed.

In the cortical substance of the *kidneys* a considerable new formation of connective tissue was met with around the Malpighian bodies, whose loops were in many places invisible, as well as around the convoluted tubes; the same was met with to a less, and sometimes quite inconsiderable extent, around the straight tubes. In the connective tissue tolerably numerous nuclei were observed, and only very scattered fat globules were seen. Of the canals many were evidently atrophied, and collapsed, others exhibited a normal or more slightly contracted bore, while some were considerably dilated, sometimes in the form of a garland. The contracted canals were in general invested with an epithelium of small cells, in one place well defined and healthy in appearance, in another without any accurate boundary, and containing granules and scattered fat globules. In the dilated canals the cells were in general highly granular, with or without intermingled fat globules, which were always few in number. Only very few more homogeneous or wax-like cells were met with. Scattered wax-like cylinders were found everywhere, but nowhere in great number. Some of the proper coats of the canals were thickened, shining, and refracted light strongly. In the pyramids the change was slight; only here and there were the cells granular, or did they contain fat granules; a few of the canals were filled with cylinders. The vessels were not injected, but from the results of microscopical examination it is probable that the vessels in the pyramids were dilated. No parts gave any amyloid reaction.

That the patient, even at the time of his admission to hospital, had far advanced Bright's disease could not be doubted. This was sufficiently proved by the low specific gravity of the urine and the nature of the deposit, the gradual development of the uræmic symptoms, the affection of the eyes, and lastly the hypertrophy of the heart, the existence of which might, with all probability, be inferred from the extensive impulse, the resonance of the sounds with the strong accent upon the second, and the headache occurring on great exertion, as well as in the

horizontal position. The diagnosis pointed to a chronic diffuse nephritis with a three-fold change in the epithelium (granular breaking up, fatty and waxy degeneration), and in the beginning abundant, and subsequently scanty, collection of wax-like masses in the urinary canals, with a probably considerable increase of stroma. In the last-mentioned assumption I felt myself justified less by the stage of the disease than by the nature of the urinary sediment, because experience has taught me, that in cases, where for a long time the urine contains wax-like cells and broken wax-like, but no hyaline cylinders, an usually considerable new formation of connective tissue exists.* On account of the excellent state of the patient's general health previously, it was thought that amyloid degeneration of the vessels did not exist, or that it existed only in a slight degree, notwithstanding that a urinary sediment of the same nature as occurred in this case is often met with in that affection. Whether the kidneys were atrophied or not was left undecided. Neither the quantity of the urine, the amount of albumen, the colouring matter, nor the quantity and composition of the sediment, nor the general symptoms of the illness, afforded any sure ground for diagnosing atrophy of the kidney, and still less for determining its degree, without an accurate knowledge of the duration of the disease, and of the causes and circumstances under which it was developed.

The commencement of the disease cannot in the foregoing case be determined with certainty. To throw it back nine or ten years, when the patient suffered from ague with and without dropsy, could be no more than hypothesis. To this view various circumstances are opposed; above all, the long latent period of development, which would in that case have coincided with the patient's progress from childhood to manhood. In favour of it, besides the absence of any other etiological standpoint, we have at least, to a certain degree, the exclusive formation of wax-like, but not of hyaline cylinders in the urinary canals, because this circumstance, usual in the last stage of the form of disease, which is developed during a tedious or relapsing ague, as well as in the course of certain chronic general affections, does not properly belong to the simpler forms, which, during its development, are free from such an influence. In Bright's disease, after ague, the changes which take place in the kidneys are both quantitatively and qualitatively very varied, according to the different period at which the renal disease had been complicated with the ague. Thus, while the well-marked cases are characterized by waxy degeneration of the epi-

* Even in the most recent and extensive treatises on renal diseases by Rosenstein (*Die Nierenkrankheiten*, 1863) and Vogel (*Virchow's Path. and Ther.*, Band vi., Abt. ii., Heft iv.), by no means sufficient attention is devoted to the various changes in the renal epithelium, to the urinary sediment and its signification in a diagnostic and prognostic respect. Thus those writers confound the hyaline and wax-like (Key's "hyaline gelatinous and hyaline wax-like") tubercasts, nor do they attach to these any importance in the diagnosis of the several forms of the disease. Vogel assumes that the hyaline casts become wax-like if they remain longer in the renal canals. The incorrectness of this view is at once evident from the fact, that broken wax-like tubercasts may be met with during the first days of an acute nephritis, and that in certain chronic forms—for example, Bright's disease after ague—innumerable broken wax-like casts may be found, while we sometimes search in vain for a hyaline cast. The granular (Vogel's "granulosa") casts are referred by Vogel chiefly to metamorphosis of the "fibrin-cylinders" and the cylinders formed of blood-corpuscles. I will not here enter on a fuller refutation of these views, as the subject has been treated of in detail by Key (*Medicinskt Archiv*, 1863, p. 233) and me (*Bidrag till kännedomen af urinsedimentet uti njurans sjukdomar*, 1862. Contribution to the knowledge of the urinary sediment in diseases of the kidneys). In a notice of the Swedish Archives of Medicine in the *British and Foreign Medico-Chirurgical Review*, vol. xxxiv., Oct., 1864, p. 427, I have very briefly mentioned the heads of Professor Key's very valuable paper just quoted.—TRANSLATOR.

thelium, the formation of wax-like cylinders, a general and considerable hyperplasia* of connective tissue, amyloid degeneration of the vessels, sometimes also of the tunica propria; in those instances where the ague and the aguish cachexy cease, before the renal disease has attained any high development, and still more where the ague has only given the impulse to the renal affection, fatty degeneration and granular breaking up of the epithelium more and more replace the waxy degeneration. The number of the wax-like cylinders is limited, the new formation of connective tissue becomes less considerable, and the amyloid degeneration becomes progressively rarer. The extremes resemble one another little or not at all. In cases belonging to the first category the kidneys are extremely rarely found in an atrophied state, which is, on the contrary, less unusual in the others. The atrophic condition of the kidneys in the above case is therefore no proof that the disease may not have arisen long since under the influence of ague.†

That no certainty can be attained with respect to the etiology of the case, but little diminishes its practical interest. The principal cause of this is, that perfect health may apparently exist during the whole development of Bright's disease. It is indeed nothing unusual, particularly perhaps among rather elderly persons, for dropsy to be absent, but it must be rare to see a patient of this kind and age with so healthy and even blooming an appearance as ours had. Referring specially to the dropsies, Traube‡ expresses the opinion, that their absence must be attributed to the coexistence of hypertrophy of the heart, which, by increasing the arterial pressure of blood in the kidneys, produces an augmented flow of urine. The importance of copious diuresis, whatever its cause may be, not only in preventing dropsy, but also in duly removing excrementitious matters, notwithstanding the functional disturbance of the kidneys, is evident. Indeed we might even assert that a copious discharge of urine is a condition *sine qua non*, of the possibility of Bright's disease running such a course as it did in the above case. At the same time it is equally necessary that the enormous loss of albuminates should be constantly made good, as otherwise hydræmia would sooner or later be the result. Should this be once established, daily experience shows that neither the hypertrophy of the heart nor a copious discharge of urine could long prevent the occurrence of dropsy.

Traube's theory, that the hypertrophy of the heart with atrophy of the kidney is produced solely by the increased general arterial pressure caused by the obstruction to the renal circulation, has, as is well known, in its exclusive shape, met with almost universal opposition. At least a contributing cause has been sought in the altered state of the blood. If one will not, like Bamberger, completely deny this mechanical influence on the occurrence of hypertrophy of the heart, our case seems undeniably to be favourable to the correctness of Traube's opinion, as in it there was no sign of any abnormal condition of the blood, and nevertheless hypertrophy, though in a slight degree, was present.

The affection of the eyes was of the form usual in Bright's disease. The white spots, proceeding from fatty degeneration of the cells in the stroma of connective tissue, did not belong, as sometimes seems to be the case, to a certain zone of the retina, but were scattered everywhere, except in the pupils and their immediate neigh-

* Key, op. cit. "General hyperplastic nephritis."

† That Rosenstein (*l. c.*, p. 211) has never met with granular atrophy in Bright's disease after ague cannot but excite surprise, the more so as it would thence appear that he probably has not observed any exquisite cases of this form of disease. He would otherwise not have referred it exclusively to the diffuse nephritis, but would have classed some cases (those according to the above belonging to the first category) under his "amyloid degeneration of the kidneys," to which both they and it belong as types.

‡ *Ueber der Zusammenhang von Herz- und Nieren-Krankheiten* (On the connexion between Cardiac and Renal Diseases), 1856, p. 59 and elsewhere.

bourhood. They probably were not located in the inner parts of the retina, as not the slightest change was found there after death. The rapid resorption of the fat, which occurred during life, and was proved after death, is remarkable. The progressive improvement of the sight with the slightness of the change met with, makes it probable that complete restoration would have been obtained, if the patient had lived longer and no relapse had occurred. Literature records only some few cases noted by Graefe and Liebreich, where the retinitis completely disappeared without injuring the sight. This result, indeed, always attends cases where the affection of the eye runs a comparatively rapid course, and where the otherwise ordinary changes in the stroma and the nerve filaments (hypertrophy and sclerosis) have not been able to develop themselves. Probably the patient's general state is not without influence. The amblyopia present during the last two days of life must have depended on slight œdema of the retina. The existence of œdema in the brain and medulla oblongata is favourable to this view.

With respect to the advanced stage of renal disease the prognosis cannot be otherwise than unfavourable even for a proximate period, especially if uræmia has already once been established. The treatment must, under the circumstances mentioned, be confined principally to supporting the patient's strength with nourishing food, and to the employment of suitable means if any threatening symptoms should manifest themselves.

As on the first occurrence of illness, the uræmic attack was on the last occasion preceded by a whole week of various premonitory symptoms. The diminution of the urinary secretion may be assumed to have depended on lessening action of the heart, as no acute process was met with in the kidneys, nor were the urinary canals filled to any remarkable degree with wax cylinders. The proximate cause of death must be sought in paralysis of the vagus, indicated before death by the rapid action of the heart and the laboured respiration, which finally passed into orthopnoea, and after death shown to be probable by the existence of considerable œdema in the medulla oblongata; the state of the lungs moreover agreeing with that found in these organs after division of the nervi vagi in animals (Claude Bernard, Boddaert). As to the convulsions, the autopsy admits of their explanation with Opolzer by œdema of the brain, or with Traube by anæmia of the same, if we do not prefer to keep to some of the other common theories. Against Frerichs' hypothesis more and more voices are raised. If the view lately put forward by Almén, Oppler, and Zaleski, that urea is formed exclusively or principally in the kidneys, should prove to be correct, Frerichs' theory falls, and we may then begin to hope for an unanimous opinion as to the cause of the group of symptoms met with in Bright's disease, as now with respect to the name "Uræmia."

ABSTRACT OF
METEOROLOGICAL AND MEDICAL REPORT
OF THE
MILITARY HOSPITAL, NICE,

FROM THE 1ST TO THE 11TH OF APRIL, 1866.

By Dr. CABROL,
CHIEF PHYSICIAN TO THE HOSPITAL.

Translated by R. CROTHERS, M.D., M.R.C.P.L., Nice.

WHEN we published our last bulletin we had reason to expect a continuance of fine weather, but have been disappointed. The ten days just passed having been amongst the most variable of the year, exhibiting the elements of the spring and the equinox so well known to meteorologists and to sailors, and which gives origin to very evident modifications in all the kingdoms of nature in the states of

health and of disease, whatever may be the climate or the relative position of the place in which they are observed.

These elements, wind, rain, hail, and storm, sudden and extreme changes, mixture of summer and winter, of heat and cold, of dryness and moisture, have been very remarkable. In these ten days we have had only four fine and bright, six cloudy, rain having fallen upon four of these days. The quantity of water amounts to nine centimètres (nearly four inches), and fell twice in the form of hail. There was a violent storm on the night of the 8th; began with frequent flashes of vivid lightning in the evening, rain towards midnight, with loud peals of thunder in rapid succession, then heavy hail, some of its remnant on the ground even until the morning. On the following night there was another storm, but less violent. The barometer has been always high, and rose to 0.766 (30 2-11th): on this subject we may remark that the instruments seem to be less sensitive in indicating those changes which come from the sea. The winds have blown almost constantly from the south. The sea, rather rough, was violently disturbed on the night of the 8th. Despite of these variations the soil has rather gained than lost by this state of atmosphere. There is not any complaint of dryness, as last year; the subterranean reservoirs are supplied for the summer, and vegetation is flourishing. With the exception of trifling ailments, the weather has not caused any particular diseases. Old affections, as asthma, rheumatism, bronchitis, &c., have naturally suffered from these unfavourable changes, but without being seriously aggravated. It is worthy of remark that, thanks to the mildness of the winter, we have seen, particularly in young persons, nervous affections and accidental feverish attacks, run their natural course, terminate by a crisis, and be cured almost without medicine, the age and prolonged sojourn in a mild climate permitting the normal evolution of the disease. This remark, made particularly at the approach of spring, is applicable to bronchitis, pleurisy, pleurodynia, affections simulating tubercles, spasms, nervous affections of a periodic character, gastralgia, hysteria, intermittent and rheumatic neuralgia. Thus it is evident to us that the climate alone, despite the changes depending upon the vicinity of the sea, is often the most powerful means of cure.

In Dr. Lee's work on Nice the mean annual fall of rain is stated to be 26 cubic inches, the greatest fall 43 inches, the least 16 inches; the largest number of rainy days 75, the smallest number 47, the mean 60, thus leaving 305 days, of which Dr. Lubanski says the average is 180 days of brilliant sunshine, and 125 days cloudy, or with partial sunshine.

FROM 11TH TO 21ST APRIL, 1866.

We begin this bulletin by the rectification of an oversight in the last. We omitted to state the temperature, which was low in the first days of the month, the mean being only 52, minimum 38, maximum 66; whilst in the ten days just passed we have had a min. temperature of 43, a maximum of 73, and a mean of 56. The barometer has been always above 0.760, indicating settled fine weather; and although the sky has been sometimes clouded, we have not had to observe either high winds or appreciable rain. The winds have been from the S.E., beginning now to assume the direction from which they blow almost constantly during the summer months. The mornings are fresh and agreeable; thanks to a slight breeze, the heat of the day is not yet unpleasant, although we have observed the thermometer at 98 in the sun, only the dust is at times disagreeable. The sea has been calm and beautiful.

If now, in order to justify for the last time, the programme which we proposed to fill up with respect to the medical constitution of the season, we pass from purely meteorological to medical facts. We see that the spring has not given origin to any new disease to be imputed directly to atmospheric influences, if we except those designated under the name of neuralgias, irritations of the throat, sense of painful weariness, &c., affections which have

been slight, ephemeral, and free from danger. The more serious diseases which we have observed were chronic, and in these the influence of the climate has tended to mitigate the suffering. Many owe to it a very evident amelioration, some even such a recovery as in other circumstances might have been very doubtful; in this number were some cases of arrested typhoid, affections of the larynx and pharynx, hooping-cough, some cases of dysentery, of asthma, of gout, &c., which were indicated by symptoms peculiar to each of these affections, but which have been slight and of much shorter duration than ordinary. Thus we believe that we have good reason to infer the superior sanitary state of a country in which, during all the winter, no epidemic tendency has been observed.

In this last bulletin we may state that the observations have been taken with the greatest care by the staff of the hospital, and we are happy to be able to thank them for their active and incessant co-operation, particularly Dr. Beaugrand ("Médecin Aide-Major") and Dr. Figuiera. Their co-operation has been very useful to us in the publishing of our bulletins and the daily record of observations.

By authority of the Prefect, bearing date the 30th Dec., 1865, a Meteorological Society has been established at Nice for the Department of the Maritime Alps.

The members of the society are to institute a series of observations in the localities most favourable for that purpose, to observe the phenomena of storms, the amount of ozone in the atmosphere, the level of subterranean water, &c.—in fact, carefully to observe and report upon all the meteorological phenomena and climate of the department and their influence upon and connexion with epidemic and other diseases.

Abstracts of the Scientific Societies.

ROYAL.—April 26.—The following communications were read:—"On the Dentition of *Rhinoceros leptorhinus* (Ow.);" by Mr. W. B. Dawkins.—"Experimental Researches in Magnetism and Electricity, parts i. and ii.," by Mr. H. Wilde.—"On the Tides of the Arctic Seas: part iii. On the Semidiurnal Tides of Frederiksdal, near Cape Farwell, in Greenland," by the Rev. S. Haughton.—"Extract of a letter from C. Chambers, Acting Superintendent of the Bombay Magnetic Observatory, to the President, dated March 28, 1866."

GEOLOGICAL.—April 25.—The following communications were read:—"Additional Documents relating to the Volcanic Eruptions at the Kaimeni Islands," by Commander Brine, of H.M.S. *Racer*.—"Report to the Eparch of Santorino on the Eruptions at the Kaimeni Islands," by M. Fouqué.—"Remarks upon the Interval of Time which has passed between the formation of the Upper and Lower Valley-gravels of part of England and France; with Notes on the Character of the Holes bored in Rocks by Mollusca," by Mr. A. Tylor.

BRITISH ARCHAEOLOGICAL ASSOCIATION.—April 25.—The Chairman announced that Lord Boston had accepted the office of President for the ensuing year. Lord Boston exhibited some articles exhumed in 1865 at Caer Leb, in Anglesey.—The Rev. S. M. Mayhew exhibited two flint arrow-heads, obtained by him in the county of Antrim.—A paper, "On Chelsea and Chelsea People," by the Rev. J. Blunt, was then read and illustrated by H. H. Burnell. Mr. Blunt first discussed the etymology of the name, and pointed to the probability of Chelsea being derived from *Ceale*, chalk, and *Hyd*, or *Hythe*, a harbour, and that this Hythe was used for landing chalk, and so had given a name to the place. Also, that it was at Chelsea that two important councils were held under Offa, King of Mercia.

ARCHAEOLOGICAL INSTITUTE.—April 9.—Some notes on recent discoveries at Carthage were contributed by the Rev. J. G. Chester. The collection of antiquities excavated is preserved in a sort of garden-house belonging to

the Khaznadar, or First Lord of the Treasury, of Tunis. The collection, which was minutely described by Mr. Chester, belongs to the eldest son of the Khaznadar, and had never before been seen by a European.—Professor Buckman described the Roman remains recently discovered in the Isle of Portland. Until very lately it has been imagined that no evidence of Roman occupation existed in Portland; but the progress of the works connected with the fortification now in operation has revealed a Roman burial-ground.—Colonel L. Fox gave a detailed description of Roovesmore Fort and oghams in the parish of Aglish, county Cork. Interference with the forts, of which Roovesmore is an example, is regarded in the south of Ireland as involving all sorts of calamities from the vengeance of the fairies, by whom they are supposed to be inhabited. Colonel Fox, however, prevailed on the owner of the fort to permit the removal of the oghams, and they are now in the British Museum.

ZOOLOGICAL.—April 24.—Mr. P. L. Sclater drew the attention of the meeting to several new and interesting additions to the Society's menagerie, amongst which were particularly noticed a pair of straw-necked ibises (*Ibis spinirollis*) from New South Wales.—Mr. P. L. Sclater read some notes on the *Geobates brevicauda* of Swainson, relating more particularly to the synonymy of this bird, and to its correct position in the natural system.—Mr. G. R. Gray communicated a description of *Penelope* lately living in the Society's gardens, and proposed to be called *Penelope Greeyii*, after Mr. E. Greey, by whom the specimen had been procured from Santa Martha, in New Granada.—Mr. A. G. Butler read a revision of the species of Lepidopterous insects belonging to the genus *Hypna* of Hübner.

ROYAL INSTITUTION.—May 1.—Sir H. Holland, Bart., President, in the chair.—The Annual Report of the Committee of Visitors for the year 1865 was read and adopted. The books and pamphlets presented in 1865 amounted to 105 volumes, making, with those purchased by the Managers, a total of 390 volumes added to the Library in the year. Fifty-seven new Members were elected in 1865. Sixty-six lectures and eighteen evening discourses were delivered during the year 1865.—The following gentlemen were elected as officers for the ensuing year:—*President*, Sir H. Holland, Bart.; *Treasurer*, W. Spottiswoode, Esq.; *Secretary*, H. B. Jones; *Managers*, Warren De La Rue, Sir G. Everest, J. H. Gladstone, W. R. Grove, C. H. Hawkins, Sir J. Lubbock, Bart., J. C. Moore, W. Pole, W. F. Pollock, L. Powell, M.D., Lieut.-General E. Sabine, Earl Stanhope, J. W. Thrupp, C. Wheatstone, and Col. P. J. Yorke; *Visitors*, Sir C. T. Bright, M.P., J. C. Burgoyne, G. F. Chambers, Capt. J. Drew, S. Gaskell, H. H. Harwood, T. W. Helps, Sir T. Henry, T. H. Hills, W. E. Kilburn, H. Mackenzie, M. Noble, Lord Overstone, T. H. Tuke, M.D., and H. Twining.

SOCIETY OF ARTS.—April 20.—"On the Synthesis and Production of Organic Substances by Artificial Means, and the Applications which some of them receive in Manufactures" (Cantor Lecture), by Dr. F. C. Calvert; Lecture II. "On the Transformation of Neutral Substances."—April 25.—The paper read was, "The Perils of Mining, and the Means for Preventing them," by Mr. J. B. Hogg.

ANTHROPOLOGICAL.—May 1.—The following papers were read: "On Hindu Neology," by Major S. R. I. Owen.—"Description of a living Microcephale," by Dr. Shortt.—"Some remarks on Indian Gnosticism, or *Sakta Puja*, the Worship of the Female Power," by Mr. E. Sellon.—"On the alleged Sterility of the Union of Women of Savage Races with Native Males, after having had children by a white man, with a few remarks on the Mpongwe tribe of Negroes," by Mr. R. B. N. Walker.

THE United States Congress has purchased Ford's Theatre (in which Mr. Lincoln was assassinated) as a museum for the medical department of the army, and for the disposal of documents relating to soldiers.

SUMMARY OF SCIENCE.

(Specially Edited and Compiled for the Medical Press and Circular.)

By CHARLES R. C. TICHBORNE, F.C.S.L., F.R.G.S.I., &c.

[The Editor of this Summary wishes it to be understood that he is not responsible for the ideas, theories, or the correctness of statements made in any of the papers quoted in the compilation.]

PRODUCTION OF LOW TEMPERATURES FOR LOCAL ANÆSTHESIA.—Mr. Crookes, the editor of the *Chemical News*, has published a table giving the results of experiments made with different liquids, the instrument used being one made by Messrs. Krohne and Sesemann for producing local anæsthesia for surgical operations.

The following experiments are taken from many others given by Mr. Crookes, except that the temperatures which are given as centigrade, are here converted into Fahrenheit's scale, as being better understood by the readers of this journal:—

Ordinary ether from methylated spirit, thermometer fell from 23° to 5°; pure ether, washed and rectified, thermometer fell to -6°; water in a test-tube held in front of the jet commenced to freeze immediately; pure ether, sp. gravity .720, prepared expressly for anæsthetic purposes, thermometer fell to about -8°. In this case considerable quantities of ice condensed round the bulb of the thermometer, so as to impede the cooling unless occasionally removed.

Absolute alcohol only took the thermometer down 10 degrees of the centigrade scale, and pure methylated alcohol only 18 degrees.

Bisulphide of carbon sent the thermometer down to 1° Fahr., but this fluid could not be used from the fact of its disagreeable smell. Large quantities of ice, however, condensed upon the bulb, coating it nearly a quarter of an inch thick. In a few minutes the sulphide of carbon ceased to issue regularly from the jet, and miniature snowballs were blown out at intervals. The distance of the bulb of the thermometer from the jet in the above experiments was half an inch.

ON THE EXISTENCE IN THE TEXTURE OF ANIMALS OF A SUBSTANCE CLOSELY RESEMBLING QUININE.—Henry Bence Jones gave a lecture on the above subject at the Royal Institution. The author and Dr. Dupré found that animal substances contained a substance which exhibited a fluorescence similar to quinine. This substance can be shown to exist in the living and dead textures. Every texture was examined, and in every one this fluorescent substance occurred. The lenses of the eyes from their transparency are, above all others, most suited for experiments. The *Animal Quinoidine*, as the authors have named it, is procured from the other textures in the following manner:—The kidney, for instance, is treated with diluted acid, neutralized with alkali, and then extracted with ether.

As regards the amount of fluorescent substance in different parts of man, the kidney, cartilages, liver, and lenses seem to contain most, but no very accurate estimation could be made.

VALEROLACTIC ACID.—Under this name, a new acid is described by M. Fittig, homologous with lactic acid. It forms well-defined salts, including sodium, calcium, zinc, silver, and copper.

TRICHINA DISEASE.—Dr. Thudicum, in a paper describing a case of death from eating raw German sausages, comes to the following conclusions:—That trichinæ can be imported in raw German sausages, and cause trichinæcasis in this country.

That muscular encapsuled trichinæ can live thirty years.

If strongly encapsuled they are, though living unquestionably, in most cases unable to withstand the powers of the stomach of various animals and, consequently, but

little capable of infecting those animals on which the trichina preys.

Ordinarily, when encapsuled trichinæ are eaten by man or animals, the capsules are digested and the trichinæ are set free. They then pass into the intestines, and there propagate themselves very quickly. Each female produces about one thousand young trichinæ in the course of a fortnight, and ushers them into the world alive, and quite prepared to eat their way to their final destination—the muscle.

The young trichinæ immediately pierce the intestinal walls, and obtain access to all the tissues of the abdomen. The greater number penetrate directly into the blood-vessels, or indirectly into them through the lymphatics, entering the circulation with the chyle. On the seventh day after an animal has taken trichinous meat the young trichinæ are found in all the tissues.

In the case reported by Dr. Thudicum (that of a German, 58 years of age) he calculates the number of worms contained in the body of this man at about 40,000,000. A microscopic specimen of the flesh would frequently show upwards of fifty of these capsules, and these were parts where the muscle seemed to consist of almost nothing but such capsules.

IMPORTANCE OF MASTICATION.—M. Mialhe says, in a paper published in the *Journal de Pharmacie et de Chimie*, that it is important that vegetable diet should be well chewed; but with meat, that mastication is not of much consequence. We should be inclined to think that the latter part of this statement entails a dangerous theory.

IODIDE OF POTASSIUM.—There have been sundry papers upon the above subject within the last few months. The following remarks are mostly taken from two published in the *Journal de Pharmacie et de Chimie*:—

“M. Payen says that iodide of potassium generally contains carbonate of potassium and iodine in excess. Iodide of potassium (either pure, slightly alkaline, or ioduretted) swells starch granules to twenty-five or thirty times their volume, dissolving their internal substance, and giving the external envelope an enormous extension.

“Bromide of potassium produces the same effects.
“The alkaline chlorides do not give either a swelling or a solution of the starchy matter.

“Carbonic acid partially liberates iodine from a specimen of the iodide slightly alkaline and ioduretted. The atmosphere produces an analogous effect, but this action ceases if it is deprived of its carbonic acid.

“Pure iodide of potassium, in the form of a saturated solution, remains without coloration when exposed to diffused light, and more than two hours when exposed to the sun.

“In the same conditions the solution of impure iodide is coloured yellow, and starch is tinted violet by it. A trace of iodine in excess can be detected immediately by the addition of acetic acid, which produces a yellow colour in the solution, and a little starch manifests the violet.

“M. Fuch publishes a process which, he says, yields a very pure product, but it has the disadvantage of requiring some time, and also the editor would give a preference to those processes in which the formation of a bulky salt of iron is avoided. The care required in washing this product is very considerable. If the proportions are so arranged that the magnetic oxide is produced, it is much more easy to wash the precipitate.

“Fuch places 100 parts of iodine into a porcelain dish with 260 parts of distilled water, and adds thereto 75 parts of carbonate of potash and 30 parts of iron filings. The mixture is well stirred together and allowed to stand. The action proceeds slowly by itself, but is hastened by the application of heat. When the evolution of carbonic acid has ceased the mixture is evaporated to dryness with continual stirring. It is better to allow the mixture to stand for some time in a lukewarm drying oven until all the iron is peroxidized, and then to evaporate to dryness.

"The dried mass is then placed in an iron vessel, and heated to dull redness. The residue is then extracted with the smallest quantity of distilled water. The solution, which has usually an alkaline reaction, is then saturated with hydriodic acid, and set aside to crystallize.

Methylated spirit is now so cheap that extraction with this menstruum is perhaps the best process that can be adopted where a very pure product is required.

"The common impurity of iodide of potassium is iodate, which is the source of free iodine in the commercial article. Iodide of potassium is rarely adulterated, but bromide of potassium is. A sample lately analyzed by the writer of this summary contained two-thirds its weight of iodide. It was beautifully crystallized.

ON COLCHICINE.—The experiments of Mr. Ludwig confirm what Mr. Oberlie has shown in this journal (*Journal de Pharmacie*), vol. xxxi., p. 248, on colchicine and its derivatives. Those which Mr. Hubler has just published complete them. He prepared the active principle by exhausting in the cold with alcohol from 90 to 100 grammes of colchicum seeds, adding to the liquid about twenty times its volume of water. He succeeded in separating an oily substance. He treated this product afterwards with basic acetate of lead to separate the coloured matter, and then by phosphate of soda to separate the superfluous lead, and finally he added some tannin, which precipitated the colchicine.

The tannin should be free from chlorophyll and all other foreign matter. The precipitation should be fractional, on account of the beginning and end of the precipitation being the least pure they are treated separately. It is very soluble in alcohol, and is not entirely insoluble in water. It is formed of three equivalents of colchicine and four equivalents of water. To separate the colchicine this precipitate is powdered with a quantity of vitrified lead, which has been washed and moistened. It is dried in a water bath. To be certain that the tannin is fixed in the precipitate should reboil in a small quantity of alcohol. The filtered liquid should not become black in connexion with sesquichloride of iron; if so, it is again diluted in some water and redried in the water bath. The colchicine is separated by means of boiling alcohol. It is dried in a vacuum over acid. By repeating this operation we obtain colchicine in a pure state. In this condition it is dissolved in alcohol and water without any turbidity. It forms a kind of varnish, reducible to a yellow powder. Its smell resembles that of hay, and is developed in contact with hot water. Colchicine has a persistently bitter taste, no odour, and does not, like veratrine, excite sneezing. Colchicine dissolves with moderate facility in water, easily in alcohol, less so in ether, and very readily in chloroform.

Strong nitric acid colours it deep violet or blue, quickly changing to olive green and yellow. It is precipitated from its aqueous solution by tincture of iodine (of a kermes yellow colour) by dichloride of platinum and tannic acid.

Colchicine is very poisonous, causing even in small doses violent vomiting and purging; one-sixteenth of a grain killed a cat in twelve hours. Tannin is the best antidote.

ON THE DEVELOPMENT OF CERTAIN INFUSORIA.—Mr. J. Samuelson had observed the regular occurrence of monads belonging to the species of *Cercomonas fusiformis* in distilled water. They readily appear when dust from any part of the world is sifted into it; also in water containing extract of lettuce they also speedily showed themselves, but in the pure water they remained unchanged until near the end of the experiment (a period of three weeks). They entirely disappeared from the lettuce infusion in six or seven days, and were succeeded by ciliated infusoria. The fusiform body of the cercomonas leaves a long whip-like cilium at its anterior end, and a short hair-like canal process at the opposite extremity. Now, this characteristic figure was retained by the monads in the distilled water. They continue to grow larger during the process of the observations, but without change of form.

On the other hand, the cercomonads of the lettuce infusion in a few days lost both appendages, and, changing their manner of swimming, began to move through the water like ordinary ciliated infusoria.

From this and other observations, Mr. Samuelson infers that cercomonads are larvæ or earlier forms of the ciliated animalcules.

MEDICAL GLEANINGS.

ON THE EXCRETION OF AMMONIA BY THE LUNGS.

By H. LOSSEN.

LOSSEN refers to the results of previous experimenters, especially to those of L. Thompson, Regnault and Reiset, and Thierry, and describes an apparatus he has devised for determining the amount of ammonia eliminated by the lungs. He finds that the quantity is scarcely appreciable, amounting to only ten milligrammes per diem, and is of opinion that this is not developed or generated in the blood or tissues, but that it originates during the passage of the air through the air-passages—the various secretions and epithelial formations which are thrown into these tubes, the presence of carious teeth, and the decomposing remains of food in the crevices of the teeth, even of the healthiest person, being sufficient to account for the presence of the exceedingly small quantity observed.—*Zeitschrift für Biologie und Brit. and For. Med.-Chir. Review.*

NOTE ON THE CAUSE OF THE REDNESS IN INFLAMMATION.

By MM. ALFRED ESTOR and CAMILLE SAINT PIERRE.

MM. ESTOR and St. Pierre have made investigations on the pneumatology of the blood coursing through inflamed parts, as the foot of a dog seared with the actual cautery. They estimated the amount of oxygen present by treating the blood with carbonic oxide, as recommended by Bernard, and obtained the following remarkable results:—

Experiment.	Inflamed side, amount of O in 100 parts of blood (venous).	Sound side, Ditto.
1	6.01	2.41
2	6.04	2.40
3	4.74	2.36
4	3.60	2.40
5	4.80	2.40

They conclude from these and other experiments—

1. That the venous blood returning from an inflamed part contains constantly more O than the blood of the sound side, the proportion being as 1 : 1.50 or 2.50.

2. That the venous blood of the inflamed side contains more CO², and

3. That it is to the excess of O in the venous blood, rendering it of brighter tint, that the increased redness of an inflamed part is due.—*Mémoires de la Société de Biologie and Brit. and For. Med.-Chir. Review.*

CASE OF FORCIBLE TEARING AWAY OF THE UTERUS OF A WOMAN JUST DELIVERED.

THE following case, related by Dr. Hoffmann, is a melancholy example of the evil resulting from the lack of habitual practice in ordinary midwifery, and the concomitant one of medical practitioners being called in almost exclusively to difficult labours:—A woman, aged thirty-nine, was in her ninth labour, under a midwife who gave a powder, soon after which the child was expelled. She immediately removed the placenta by drawing on the cord. Strong after-pains followed, and the midwife felt a fleshy mass in the vagina. The district surgeon found the patient pale, cold, and almost pulseless, and a dark red fleshy mass projecting from the vulva. As he could not return it, he took it for a growth or fleshy mole, and passed his hand near the mass and through an opening which he took for the os uteri. After twenty minutes' manipulation he directed the midwife to take away the mass. Imme-

diately this was done a loop of intestines appeared. The mass torn away was the uterus. The examination of the body showed that the lower part of the vulva, together with the perinæum as far as the anus, was torn off, and no trace of uterus, ovaries, or Fallopian tubes was found.—*Vjhrschr. f. gerickeilich. Med. and Brit. and For. Med.-Chir. Rev.*

ON CERTAIN MODIFICATIONS IN THE MANAGEMENT OF TURNING BY THE FEET.

By Professor MARTIN.

PROFESSOR MARTIN says that he has abandoned the dorsal or supine position of the patient during the operation of turning, and now prefers to place the patient on that side to which the pelvic extremity of the fœtus is directed, whilst he places himself behind the back of the woman, and fixes the fundus uteri with the homonymous hand of the side upon which the woman lies; thus, with the right hand when she lies on the left, and *vice versa*. Thus we avoid collision with the promontory, and whilst the uterus with its burden sinks down from the pelvis, there is more room for the hand. He advises to seize only one foot.—*Monatsschr. f. Geburtsk. and Brit. and For. Med.-Chir. Rev.*

EXPERIMENTS ON DEGLUTITION, MADE BY MEANS OF AUTO-LARYNGOSCOPY.

By M. H. GUINIER.

IN the number of the *Comptes Rendus* for May 1st, 1865, is a communication from M. Guinier of Geneva, tending to show that during normal deglutition the alimentary bolus enters the larynx, and penetrates into the larynx as far as the vocal cords before passing into the œsophagus. It is evident that M. Guinier had been led into error by the insensibility of his mucous membrane. In fact, in his experiments he voluntarily permits the bolus to fall into the larynx, instead of making the movement of deglutition, and of transmitting it normally into the larynx.—*Brit. and For. Med.-Chir. Review.*

A CASE OF LITHOPÆDION.

DR. R. WAGNER describes the dissection of a woman, aged 68, who had died suddenly. She had borne five children at twenty-four, and believed herself again pregnant, when she fell sick of typhus. During this illness the movements of the child ceased. Notwithstanding that the child had been retained twenty-nine years in the abdomen, it was entire, although much contracted. It weighed 3½ lbs., and was of the size of a child's head. The soft parts were much dried; some bones showed strong calcification; the scalp and one ear had grown to the membranes. Whether the extra-uterine gestation were primary or secondary, Dr. Wagner does not decide. The woman had rejected an offer of Cesarean section twenty-nine years before.—*Arch. f. Heilk. and Brit. and For. Med.-Chir. Review.*

BEER CONTAINING LEAD AND COPPER.

DR. VERVER found that in many of the beerhouses in Maestricht the beer contained lead and copper. In those houses which were most frequented this was only the case in the morning; it was no longer so when a large quantity had been drawn. The origin of the poison is, beyond doubt, due to the use of copper taps and leaden tubes, connecting the vessels with the pump on the buffet. A number of cases of lead colic had occurred in Maestricht, especially among the factory workmen, who were in the habit of drinking a glass of beer early in the morning.—*Schat der gezondheid and Brit. and For. Med.-Chir. Review.*

AN inquest was held last week on the body of Joseph Wells, aged 14, lately in the employ of Mr. Burrows, builder, of Clapham. The deceased took a bottle and swallowed a portion of its contents, which proved to be vitriol. Carbonate of soda was administered, with a view to neutralise the effect of the poison, but the deceased gradually sank, and expired. Verdict—"Accidental death."

Reviews.

A TREATISE ON THE PRINCIPLES AND PRACTICE OF MEDICINE; designed for the Use of Practitioners and Students of Medicine. By AUSTIN FLINT, M.D., Professor of the Principles and Practice of Medicine in the Bellevue Hospital Medical College, and in the Long Island Hospital, Fellow of the New York Academy of Medicine, &c. Philadelphia: Henry C. Lea. 8vo, pp. 867. 1866.

OF late years we are very much indebted to our American brethren for several large and learned works, which have greatly tended to maintain and extend the influence of our profession, not only in their own country, but in every place where our common tongue is spoken. Who that is familiar with the names of Wood, Bache, Beck, Stillé, and many others, will not bear us out in this assertion?

Under these circumstances we turned with no small degree of expectation to Dr. Flint's large and closely printed volume, written, as it is, on a well-tryed and worn subject; and while—as is always the case where men think at all—we find some things to which we may consider ourselves fairly entitled to take exception, and others which are not so fully dilated on as we may think the subject demands, yet the book is a valuable addition to medical literature. Its style is, perhaps, not the best; but its terse conciseness fully redeems it from being ranked among heavy and commonplace works, while the unmistakable way in which Dr. Flint gives his own views is quite refreshing, and far from common. Obsolete opinions or doctrines, or discussions on controverted pathological questions are rarely entered into, and the reader must look elsewhere for information on matters relating to surgery, obstetrics, diseases of women and children, and cutaneous diseases. The writer's object seems to have been to keep prominently before the mind the practical application of medical knowledge to diagnosis, prophylaxis, and therapeutical indications.

The work is composed of two large divisions—Part I., On the Principles of Medicine, or General Pathology; and Part II., On the Practice of Medicine, or Special Pathology. The former division comprises ten chapters, and we feel bound to say that these contain much, and in many cases minute, information; on the anatomical changes in the solid parts of the body; on the morbid conditions of the blood; the causes of disease; symptomatology; and general therapeutics.

On the second division we may make a few remarks in illustration of Dr. Flint's views on some contested questions among ourselves. In describing the treatment of acute pleuritis, he enters fully into the bloodletting controversy, and avows that he would rarely practise it, and then only whenever the promptness with which its effects are obtained renders it desirable to adopt it in preference to other measures producing the same effects with some delay. On page 30, he observes:—

"The useful effects of bloodletting may frequently, if not generally, be obtained by other means which require less circumspection in their employment, because, if injudiciously resorted to, they are in a less degree hurtful. The mass of blood may be temporarily lessened by saline purgatives and diaphoretic remedies, conjoined with a restricted ingestion of food and liquids. Depletion is obtained in this way without spoliation or impoverishment of the blood."

On the vexed question of the change of type in disease, Dr. Flint thus writes on page 131:—

"The opinion is held by some that diseases and the human constitution have undergone a notable change during the last quarter of a century, and that bloodletting and other antiphlogistic measures are less appropriate now than formerly on this account. This opinion seems to me not well founded. After a professional experience extending beyond

the period just named, I do not hesitate to express a conviction that acute inflammations at the present day are essentially the same as they were twenty-five years ago, and that antiphlogistic measures were no more appropriate then than now.

"Were it true that such changes have occurred, the fact would strike at the root of medical experience. If changes requiring a revolution in therapeutics are liable to occur with each successive generation, it is evident there can be no such thing as permanent principles of practice in medicine; the fruits of experience in our day, which so many are striving to develop, will be of no utility to those who are to come after us."

These opinions, expressed as they are in terse and clear language, are, of course, quite opposed to the views of Stokes, Watson, Law, and others, and they agree pretty closely with the opinions of the late Dr. Todd and of Dr. Hughes Bennett. It must be admitted that a good deal can be said on both sides of this question. Young men who adopt the principles of the new-light school of Todd and Bennett are always reminded by their grave seniors that after all it is but a question of experience, and that, as they knew nothing of practical medicine thirty years ago, so they cannot compare the type of acute disease as it occurred then with the actual state of things now. Here, however, a grave senior sides with his younger brethren, and gives his experience of the acute disease a quarter of a century ago, the said experience being absolutely contradictory to that of other keen observers of the same time. Verily, doctors differ.

Dr. Flint's treatment of cholera may be thus summarized: Prior to collapse he endeavours to arrest the intestinal effusion, and this he has frequently succeeded in doing by the internal administration of opium:—

"The article (he writes) which I have been led to regard as most eligible is a salt of morphia, administered by placing it on the tongue. . . . A grain of a salt of morphia is rarely, if ever, too large a dose for an adult. A physician should, if possible, remain with the patient. If the first dose be quickly rejected, a second should be instantly given. The doses are to be repeated at intervals of from half to three-fourths of an hour, until the dejections and hiccorygm cease. If, owing to the occurrence of vomiting, the administration by the mouth be ineffectual, it should be given by the rectum; and in cases in which the symptoms are urgent, both modes of administration should be resorted to. The system, even in this stage of the disease, is not readily affected by opiates."

Dr. Flint adds:—

"I have repeatedly succeeded in arresting the disease by this plan of treatment, and when arrested before proceeding to the stage of collapse, the recovery is usually speedy." (Page 429.)

In the stage of collapse, Dr. Flint advises the use of opium freely, yet so as not to produce narcotism. If the stomach will retain astringents, he advises their use; and he recommends, for allaying vomiting, hydrocyanic acid, creasote, and chloroform. In the stage of reaction, he advises stimulants, alimentation, diuretics, and tonics.

Dr. Flint does not believe in the identity of typhus and typhoid fever. He thus gives "the more important of the facts on which the doctrine of their non-identity is placed:—"

"1. Typhoid fever is characterized by peculiar and remarkable abdominal lesions, which are not found in cases of typhus. The difference between a fever with and a fever without these lesions is hardly less striking than the difference between a fever with and a fever without the cutaneous lesions—that is, the eruption characteristic of small-pox. The abdominal lesions of typhus fever are of so special a character as in themselves to constitute a valid claim for the individuality of the disease.

"2. The events of the clinical history in the two diseases show points of contrast which denote the distinct individuality of each disease. The more striking of these points of contrast relate to the abdominal symptoms and the

eruption. The characters of the eruption alone suffice to show that the diseases are not identical. The eruption in each disease belongs to a different class—viz., in typhoid to the *papule*, and in typhus to the *macule*. The difference is nearly as great as between the eruption of rubeola and that of scarlatina, and it is worthy of note that the two diseases just named have been considered identical within the present century.

"3. There is reason to believe that typhus and typhoid fever have each its own special cause or causes—that is, a cause or causes which will not produce the other disease. Jenner traced the origin of cases received into the London Fever Hospital during two successive years (1848 and 1849), in order to determine whether two or more cases coming from the same habitation afforded examples of the same kind of fever or of different fevers. Forty-four localities in 1848 furnished 101 cases of typhus, and only one of these houses furnished a case of typhoid fever. Eighteen localities in 1849 furnished 51 cases of typhus, and none of these houses furnished a case of typhoid fever. During these nine years nine localities furnished 19 cases of typhoid fever, and these houses furnished only one case of typhus. Similar investigations pursued by Murchison, Gairdner, Peacock, Wilks, and others, have led to similar results, showing that the two fevers have no community of origin.

"4. Neither typhus nor typhoid fever, as a rule, is experienced twice; but neither exempts from the other. Patients admitted with typhoid fever into hospital fever-wards containing cases of typhus are liable to contract the latter, and pass successively through both diseases. Several examples of this kind have come under my observation.

"5. Certain laws with respect to causation go to show their non-identity. Typhus is chiefly diffused by contagion, typhoid is rarely communicated. Typhoid fever is indigenous in many regions where typhus is very rarely, if ever, generated. After 50 years of age the susceptibility to the typhoid poison is almost *nil*, whereas typhus is often contracted after this age. Typhus prevails as an epidemic, but typhoid is usually an endemic disease."—(Pp. 723-724.)

It must be borne in mind, however, that in Ireland, where typhus sometimes presents characters all but unknown, even to English writers and observers, some men of note maintain that typhoid is merely a variety of typhus; and others hold that many cases occur in which some of the most prominent symptoms of both diseases, or varieties, are to be met with at the same time and in the same individuals.

The opinions of Dr. Stokes, long since published in America, cannot be overlooked, or lightly dealt with, nor can those of Dr. Henry Kennedy, who, we believe, advocates the last-named view (with which our own experience in hospital and private practice coincides) be treated with any other than deep consideration.

In Dr. Flint's views just noted, prominence is given to the character of the respective eruptions in fever, and the reader need only refer to the views of Dr. Lyons, as given in our "Hospital Report" of the 9th inst., to see the great importance of establishing a clear agreement as to the meaning of words in discussing this question. On the typhus and typhoid matter we may further refer the reader to the able lectures of Sir D. Corrigan and Dr. Banks, recently published in our columns.

At page 376, Dr. Flint deals with the important subject of dipsomania, not often referred to in our text books, and we feel bound to say that his remarks are fair and temperate. His remarks on "Banting-ism" on page 75 are also a novelty in a medical treatise of this kind. Writing of Mr. Banting's celebrated pamphlet, he remarks:—

"The management of obesity has undoubtedly received too little attention; but it is to be borne in mind that a system of diet suited to diminish an undue accumulation of fat may be not only inappropriate but hurtful to persons who do not suffer from corpulence."

Respecting the propriety or otherwise of performing tracheotomy or laryngotomy in diphtheria, Dr. Flint observes that there is undoubtedly less hope of success from surgical interference than in croup. The simple

question, however, is (he writes), "are lives ever saved by it? This question is undoubtedly to be answered in the affirmative." We cannot pursue this subject any further, nor are we able to enter more at length, as we should desire, into Dr. Flint's work. It is a book of enormous research; the writer is evidently a man of observation and large experience; his views are practically sound and theoretically moderate, and we have no hesitation in commending his *magnum opus* to our readers.

London Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 16, 1866.

THE FRANCHISE OF MEDICINE.

AMONGST the representative anomalies which have lent weight to the arguments of the Reform party in the recent debates, there is none which claims more attentive consideration or has received less than the position of the Medical Profession and its relation to legislation in its own arena. No measure has within our recollection received so searching an investigation or been so exhaustively discussed in all its bearings and in every interest, and the fact is eloquent of the political status of medical men, that their right to special franchise was never even once mentioned. It was, of course, not to be expected that special claims could be considered on the reading of the Franchise Bill, but the Redistribution Bills afford us no more promise of medical representation, and we seize the earliest opportunity to throw down the gauntlet on the part of the Profession, and demand from its delegates an earnest effort to place it in the rank to which its numerical strength, its intelligence, and its public importance entitle it.

The claims of the Profession are, we think, neither doubtful nor difficult of proof. It is a matter of the simplest statistical calculation to establish for medicine a position second to none of the learned professions which at present enjoy an ample representation in the House of Commons, and to show that, neither directly nor indirectly, are the interests of medical men or their opinions enunciated in the Councils of the Empire. Furthermore, it needs the smallest research into the past legislation of the country to show that the injurious result of such non-representation on the efficiency of the public service in all matters sanitary, domestic, moral or administrative, which come within the scope of medical science.

The numerical strength of the Medical Profession, though not its strongest argument, is nevertheless sufficient to entitle it, on the showing of the framers of the Reform measure, to considerable respect.

The names, addresses, and qualifications of the medical men of the United Kingdom are in the hands of every man in the General Medical Register, and they number nearly eighteen thousand practitioners, divided between the three Kingdoms, in the proportion of about

fourteen thousand five hundred for England, two thousand for Ireland, and one thousand five hundred for Scotland. If seats were apportioned to the Profession in the same proportion as to county and borough constituencies, let us see how matters would stand from the following returns:—

PROPORTIONATE NUMBER OF ELECTORS ON THE 31ST OF DECEMBER, 1865, TO EACH SEAT.

England and Wales—Boroughs	1380
Counties	3350
Scotland—Boroughs	2413
Counties	1666
Average for England and Wales	2365
Average for Scotland	2040

The electoral returns for Ireland not having reached us, we are unable to give the proportion of electors for that portion of the kingdom. This proportion would therefore entitle the Medical Profession to six seats in England, one in Scotland, and two in Ireland; but it is to be borne in mind that in accepting this average we have taken a standard on which dozens of boroughs of an electoral strength under 1000 would be disfranchised, and if we were to measure the representation of the profession by the small constituencies which return members, we should claim for it four times that number of seats. Let us see now whether the profession has its due. In speaking of this question on a former occasion we gave the following *epitome* of the constitution of the last Parliament:—

Landed Gentry	302
Law	131
Trade	91
Army and Navy	122
Medicine	1
Total	647

"The House of Lords, also, while it is of course chiefly composed of the landed aristocracy, contains twenty-seven Prelates of the Church and a considerable number of Law Lords and representatives of the Military and Naval Services. The Upper House, however, is a *sanctum* into which no medical man, however well educated, industrious, celebrated, or successful, ever enters; and we know that the proposal to admit the father of our profession as a Peer was indignantly scouted by the Government and the Upper House."

We are bound to modify this estimate now, for we can boast of three medical M.P.'s—Dr. BRADY, the member for Leitrim, who is the unit in the foregoing estimate; Sir JOHN GRAY, who sits for Kilkenny; and Dr. CLEMENTS, who represents Shrewsbury.

Of these gentlemen only the latter can be said to be a medical man, or in any respect to reflect professional opinion or interests, the two other members being doctors only by accident, who are neither chosen by the profession nor their spokesmen in the House.

It is not necessary for us to go further in the proof that Medicine has no place in the councils of the nation, or that the medical men of England, Wales, Scotland, and Ireland are worthy of holding such a position as the members of other learned professions possess.

We, of course, anticipate the reply to all this that if medical men are so numerous, so intelligent, and so in-

fluent, they have already their just position in the country, and can make themselves heard in Parliament through representatives not absolutely their own. It is necessary for us, therefore, to show reasons why the Medical Profession should be dealt with in an exceptional way, and enfranchised by a system different from that under which Aristocracy, Law, Divinity, War, or Commerce obtain their representation. There are, we assert, peculiar reasons why medical men cannot represent themselves in Parliament or be duly represented by others: why it should be essential for the public, as well as their own interest, that they should have a voice in legislation.

A combination of circumstances has placed medical men in a peculiar position. In the first place, they are not represented as the Church is, by the admission of twenty-seven of their body to the House of Lords, and they cannot be so because they have no official Governmental position such as the Church enjoys. Every doctor is essentially a working man labouring to his life's end for himself alone, unsupported by any system or corporate protection, such as the clergy have, and no medical man can ever claim his place as a tribune or leader amongst his class. We have no Archbishop, Bishop, Dean, or Archdeacon independent of pecuniary considerations; we are all curates without hope of promotion or sinecure.

Then, again, medical men have not the prospective inducement of an Attorney-Generalship, or the Bench, nor the prospect of security in affluence to enable them to look for parliamentary honours as lawyers do. To a medical man, a decided political bias is ruinous, while to a lawyer it is all powerful, and the course of partisanship, which lifts a barrister from the stuff gown to the bench, would reduce the resources of a medical man by one-half. Lastly, the members of the profession are distinguished from the commercial branch of the legislature by the fact—a damning one as regards their hopes of influence—that the enormous fortunes which place the trade of England in so commanding a position can never fall to their lot.

It thus appears that medical men have never been, nor can ever be, under the present system, in the enjoyment of their due rank in the legislature. Is it right that their special case should be refused a remedy? We do not hesitate to assert that sanitary and medico-political legislation has fared worse than any other from of law-making. The Medical Act of 1858, looked forward to and hoped for by the entire profession, has turned out a worse than useless burden on its resources, because the framers of the measure had neither information on their own part, which nine out of ten medical men have, nor the advice which a few medical representatives could have given them. The machinery of the sanitary enactments, which are of such vital import at this moment, is cumbersome and irksome because the prime actors in it are not consulted, and no member can be expected to speak with authority on matters as far from their province as rifled guns are

from that of the Archbishop of Canterbury, or Registration of Title from the War Secretary. The profession will, in the proposed enfranchisement of the University of London and the Queen's University, receive a very meagre instalment of its legitimate influence, for no representation of the profession can be satisfactory which is not wholly and solely medical. There is not one of our medical or surgical corporations which does not possess a larger constituency than that of many boroughs now returning a member. We have amongst us the real elements of representative power—sufficient numbers—advanced intelligence and moderation of opinion; we have men amongst us willing and competent to take on a high position in the Legislature, and we have claims on the score of both right and expediency which should be paramount, and which cannot be long foreborne.

THE REPRESENTATION OF THE QUEEN'S UNIVERSITY IN IRELAND.

SIR D. J. CORRIGAN, BART.

WE have long and earnestly advocated the representation of the Profession in Parliament. We trust that at no distant day our Colleges of Physicians and Surgeons will return a Member of their own to the House of Commons. Meanwhile in the extended representation of the Universities as scientific centres, which the recent measure contemplates, we recognize a step in the right direction; and should the franchise be conferred on the Graduates of the Queen's University in Ireland, we anticipate that the occasion which will be thus offered will be gladly availed of to return to Parliament a man not alone qualified to represent the Profession which he adorns, but who has proved himself the able and successful champion of every interest which has attached to the Queen's University from its foundation. We have reason to believe that Sir DOMINIC CORRIGAN is fully prepared to make that sacrifice of his professional time which would be entailed by attendance on Parliamentary duties. He is a man well versed in public and professional affairs, a writer of the highest scientific reputation, a ready and accomplished speaker, and a debater of unusual ability and address. Therefore Sir DOMINIC's accession to the House deserves to be actively promoted, not alone by the Medical Profession in Ireland, but by all enlightened members of the community. A man of the most large and liberal views, his voice and pen have already done good work in the public service, while the profession to which he belongs has ever found in him the most uncompromising and able supporter of its rights. No political or narrow sectarian views should be allowed to sway the Graduates of the Queen's University in this the first exercise of their franchise right. As a man of science, as well as a great Physician, and as the untiring advocate of the privileges and advancement of all the faculties which centre in the University, Sir DOMINIC CORRIGAN has peculiar and unchallengeable claims on the electors of the Queen's University.

MEDICAL PERSECUTIONS—THE CASE OF DR. ARMSTRONG.

WHEN we, as one of the organs of Medical opinion in the British empire, observe the names of one after another of the most respectable and honoured names among our profession, gibbeted in the public newspapers as defendants in trials at law brought by unscrupulous adventurers or ungrateful paupers, on the most flimsy or even groundless pretexts, we are forced to exclaim in the words of CICERO, in the commencement of his orations against the conspirator CATILINE, "Quousque tandem abutere patientiâ nostrâ? Quamdiu etiam furor iste tuus nos eludet? Quem ad finem sese effrenata jactabit audacia?" How long, we may paraphrase the passage, shall the law, which in its essence and nature is intended to be the reflex and the mirror of justice, remain the scourge of the good and the honourable, and a deadly weapon in the hands of the vile and the worthless? How long shall our courts of justice (so-called) be detained for days together in the hearing of causes against members of our profession, who are forced, at an enormous waste of time and money, to vindicate their character and their fame against worthless opponents to whom the practice of our law-courts, as they are at present constituted, affords ready opportunities for persecution and annoyance?

The "effrenata audacia" conferred by the modern practice of the law, was never more conspicuously displayed than in an action tried very lately in the Court of Exchequer in London, and of which we give a report in our present number. Of the special facts of the case we know nothing beyond what appears in the published accounts of the trial, but we know that Dr. ARMSTRONG has always held a most honourable position in his profession which he has exercised in a blameless manner for nearly forty years; and yet we see this gentleman put exactly on a level with the most disreputable quack, so far as his legal status is concerned, and dragged to London to defend himself against a charge so utterly and transparently groundless, that it appears wonderful how it could ever have been made, and still more how solicitors and barristers could have been found to sustain it.

We have not the disposition to inflict upon our readers any detailed analysis of this trial, as indeed the facts speak for themselves and need no comment. The plaintiff appears to have been a person in a very humble condition, and (according to the evidence) hardly able to procure for herself the necessaries of life, and was a casual patient at some charitable institution at which Dr. ARMSTRONG and his son happened, unfortunately for themselves as far as this case is concerned, to hold the position of Honorary Medical Officers. She was afflicted apparently with some scrofulous affection, which was of an obstinate character, and resisted the remedies employed, and a cure was moreover retarded or perhaps rendered impossible by the straitened circumstances of her condition which prevented her from obtaining a due

supply of food or even fresh air. Yet, solely and entirely on the ground that she did not recover her health, she brings an action against those who had charitably and kindly done their best to alleviate her sufferings and drags them before a judge and a jury to defend themselves against a charge of malpraxis.

We are unwilling to speak harshly of this poor creature, and we must compassionately believe that she has been deluded by some officious busy-bodies into taking the unfortunate step which has terminated in a verdict against her. In most trials of this kind there is a needy or rascally attorney in the background who somehow or other always contrives to reap some pecuniary advantage from somebody who happens to be involved in the suit, although we do not by any means allege that such is the case in the present instance. But as there must be persons belonging to the honourable profession of the law who have been engaged on the part of the plaintiff in this most shameful case, we can only believe that they have been deceived as to the probabilities of success in bringing this action, and that they will now, in vindication of their calling, explain to the Medical Profession, whom they have seen outraged in the persons of the Messrs. ARMSTRONG, the motives which led them to take up a case which, upon reflexion, they must now see was hopeless from the first, and could be calculated only to inflict pain and entail expense upon all parties concerned.

THE MEETING OF THE MEDICAL COUNCIL.

THE Parliament of the Medical Profession will meet tomorrow, but its proceedings have hitherto resulted in so little benefit to the constituency it professes to represent, that the fact of its assembling causes very little interest. The overworked and underpaid members of the Medical body look with indifference at the long and often useless discussions in which the Medical Council is generally engaged, and in which too often personal interests are more consulted than the general good; while the aristocracy of the profession, having nothing either to gain or lose by changes in legislation, are equally apathetic as to the proceedings of a body which appears to have no power and no influence, even if vigorous measures were desirable.

We make no complaint or accusation against any of the members of the Medical Council in their individual capacity; many of them are eminent in their respective departments, and all are, no doubt, actuated by what they conceive to be honourable motives. But the very constitution of the Council is of such a heterogeneous nature, and represents so many conflicting interests, that uniform action in any one direction seems to be utterly impossible. Some of the members hold lucrative appointments, and are independent of any changes which the Council may originate; others hold positions in the educational institutions of such a nature that efficient and honest legislation might materially depreciate their incomes; and a few, although neither officials nor pro-

fessors, are well acquainted with the whole question of medical politics, and endeavour, as far as in them lies, to exercise a beneficial influence upon the discordant elements around them.

The question, above all others, which the commonalty of the Profession desire to have settled as soon as possible is the position which they hold among the public as an educated body, and the advantage they gain by the operation of the Medical Act. Hitherto, we say it with all seriousness, almost the only effect of that measure has been to inflict a penalty varying from two pounds to five pounds upon all the honest members of the Profession, and to strengthen the position of those dishonourable and uneducated quacks who have so long usurped the functions of Medicine, and have so seriously damaged it in public reputation.

When we find a widely-read journal like the *Times* confounding together the wild fancies of the lowest charlatans with the doctrines of legitimate Medical science and experience, we may almost excuse its readers for falling into the same mistake, but we cannot help lamenting that the Profession possesses no influential organ powerful enough to counteract the mischievous tendencies of writers such as those to whom we allude, and to expose their ignorance to the world. In the case of the meeting of the Medical Council we shall, in all probability, find that no mention of it whatever will appear in any of the lay journals, which, however, will diligently insert all matters relating to almost every other interest but the Medical. Clerical meetings, law reports, horse races, will all be duly chronicled; but as to the Medical Profession, its pursuits are seldom mentioned but in terms of depreciation, except, indeed, when some medical or pseudo-medical friend of the Editorial Staff may have some crotchet to ventilate, when his crude, or it may be mischievous, notions are paraded before the multitude as the emanations of wisdom, to be reverently received like the aphorisms of HIPPOCRATES or the discoveries of a HARVEY or a BELL.

The only body which might have been expected to vindicate the character and defend the rights of the Profession is the Medical Council. At present it has done nothing, and the question is, whether it ever will do anything in return for the large sums already expended upon its meetings.

Notes on Current Topics.

THE *TIMES* AND THE CATTLE PLAGUE.

THE following remarks on the Cattle Plague in a recent number of the *Times* are capital, and the only regret is that it did not entertain and express the same sentiments six months ago. On the contrary, it did all it could to throw ridicule upon the very principles which it now so warmly advocates, and strove its utmost to prevent the adoption of those sanitary precautions which the Medical Profession and [the Medical Press pointed out from the first as the only efficient preventives of the disease:—

“We are taking our leave of the Cattle Plague Commis-

sion, but, unhappily, it by no means follows that we are taking our leave of the Cattle Plague itself. Its contagious nature has been most plainly manifested by the manner in which it has yielded to the preventive measures applied to it. There is in it none of that capricious and uncertain element which is the peculiar mark of so many kinds of epidemic disease. If neglected, it spreads; if energetically combated, it recedes. It is like a fire, which can be extinguished or beaten back, but which, if let alone, will spread till no more combustible matter is within its reach, and which is, perhaps, best dealt with by destroying whatever might enable it to continue its course. This steady, and, so to speak, mechanical, power to increase makes the disease more terrible, but also, it must be admitted, more manageable. It is not like the pestilence which strikes down its victims without the possibility of guarding against or foreseeing its attacks. It comes to us in a manner perfectly comprehensible, acting upon laws which we can trace and upon principles which we can perfectly understand. There is nothing arbitrary, nothing obscure, nothing capricious about it. It is a fair duel between a noxious power of nature and human skill and perseverance. Had the matter been better understood, or even had that which was understood been acted on with more energy and more intelligence, we might have escaped with a loss infinitely smaller than that which we have undergone. If we will even now take warning, and adhere to those simple but efficient remedies with which experience has furnished us,—the prohibition of fairs and markets, the stopping of traffic on railways and on common highways, the observance of a strict quarantine, and the slaughter of foreign cattle immediately on their arrival, together with the destruction of all infected animals and of all that come within the reach of infection,—we may reasonably hope to escape without any further very severe loss. Henceforth the responsibility for the rinderpest falls wholly and solely upon Government. They are armed with ample authority, and if they do not efficiently use it they must expect to be held just as much responsible for the visitation as if they failed to protect our coasts from insult or our trade from pirates. It is a new example of Ministerial responsibility, and we hope it will be strictly enforced.”

AN OUTBREAK OF AN UNUSUAL ZYMOTIC.

WE have heard on good authority that two deaths occurred on last Saturday in Dublin under most anomalous circumstances. In one case death resulted in twelve, in the other in twenty hours, the only symptoms being rapid prostration, failure of circulation, and the pouring out of great effusions of blood in and under the skin. The cases bore great resemblance to that of a medical student whose death we recorded some six weeks ago. We understand that the features of the disease were so unusual that the physician who attended one of the cases could only compare it to the “Black Death” of the sixteenth century.

We hope in our next to be able to place before our readers a full report on the subject, and meanwhile we would ask what preparations have been made for the retention in quarantine or the treatment of persons suffering from cholera, who may at any moment arrive from Liverpool or Rotterdam at this port.

So far as we can learn the Privy Council has not been stirred itself on the subject, whereas in England that body, with the aid of its able Medical Officer, Mr. SIMON, has made most timely arrangements with regard to quarantine and other measures for the suppression of the dreaded epidemic.

On Thursday last the Municipal Council and the South Dublin Poor-law Guardians suggested that a ship in the river should be set apart for such a purpose, but since then the matter does not appear to have attracted attention.

THE late Mrs. Thwaytes, of Charmandean, has left £5000 to the Sussex County Hospital.

PROFESSOR STRUTHERS ON THE EDINBURGH ANATOMICAL SCHOOL.

(Concluded from page 496.)

ALEXANDER MONRO, *Secundus*.

THE second Monro was appointed Professor of Anatomy at the age of twenty-one, before he had taken his degree or finished his studies in the University. The father's petition to the Town Council, to express it shortly, but not more plainly, was, that by-and-by he would require a successor; that he thought his youngest son, Alexander, had the necessary qualities; that his son could not venture to forego other prospects and prepare himself for anatomy on the chance of the appointment; but, if they would now appoint him his successor, he would have the young Professor educated for the office under the best masters. The petition was supported by his colleagues in the University, and was at once granted. The appointment fortunately proved an excellent one; and we might have conceded to the parties concerned the merit of having thus early discovered the talent and aptitude of the youth, were it not that the same argument, supported by the same recommendation, was submitted to the patrons for the appointment of the third Monro.

The young Professor having finished his studies and graduated more than a year after his appointment, the bargain for his education was faithfully carried out by sending him to London, Leyden, Paris, and Berlin, between which he spent two years and a half, chiefly in the study of anatomy. Besides his father, his anatomical masters were—William Hunter, who was fifteen years his senior; in Leyden, Albinus; but, above all, the German anatomist, Mickel, in whose house he lived during his long stay in Berlin.

Returning to Edinburgh, he commenced to teach in 1758, four years after his appointment. The father, after giving the first few lectures of the course, gave place to the son, who, it will be admitted, commenced boldly, for he began in his very first lecture by controverting some of the doctrines which his father had taught. His style was lively, argumentative, and modern, compared with that of his more venerable colleagues, and the effect is described by one who was present to have been like an electric shock to the audience. It was at once seen that he was master of his subject, and of the art of communicating knowledge to others; and from that day onwards for half a century his career was one of easy and triumphant success.

The number of students in Edinburgh continued to increase; and although we have no exact statement for each year, the number in the anatomy class rose, in his time, from 200 to about 400.

Monro's earlier writings were chiefly controversial, disputing claims to priority in discovery with William Hunter, Hewson, and others. He had taught for twenty-five years before he began to publish the greater works on which his reputation as an anatomist rests. In 1783 appeared his "Structure and Functions of the Nervous System;" in 1785, his "Structure and Physiology of Fishes;" in 1788, his "Description of the *Bursæ Mucosæ*;" in 1794, his "Observations on the Muscles;" and his last work, "On the Brain, the Eye, and the Ear," appeared in 1797, nine years before he retired from anatomical teaching.

Although it might well be supposed that Monro had work enough with his class, and with his anatomical researches, he was at the same time busy in practice—being, in fact, the leading physician of his time. In the words of Dr. Gregory, who was his colleague, and, as a physician, so far his rival, for thirty years, Monro was "for more than half a century at the head of the great medical school of Edinburgh, and for the greater part of that time unquestionably at the head of his profession in Edinburgh and in Scotland." This, notwithstanding that among his colleagues were, not only John and James Gregory, but the illustrious Cullen. Cullen began as Professor a year after Monro's appointment, but had the disadvantage of being a stranger in Edinburgh. Monro's name, however, is not to be put alongside of Cullen's as a great physician, nor has he left his mark on medicine as Cullen has. His true reputation was as anatomical teacher and anatomist.

In regard to how far Monro deserved his great reputation, it may be admitted that he had absolutely no difficulties to contend with as his father had, that he was born both to a

great name and a great position, and that his position was one in which a somewhat better than ordinary man is in his lifetime apt to be mistaken for a great one. But the most dangerous of all successions is that to a famous father, and the most trying position for reputation is that of having brilliant colleagues. Among these colleagues in medicine were Cullen, Joseph Black, the Gregorys, the Rutherfords, the Homes, John Hope, and latterly Dr. Duncan, senior, and Charles Hope; and in the University at the same time were Adam Ferguson, Dugald Stewart, Playfair, Dalzell, Robison, Hugh Blair, and Principal Robertson. It was a period of great men, and among all these men Monro held his place, intellectually and socially; and in his own faculty was all that is implied in describing him as the acknowledged head of the medical school, and at the same time the leading practitioner of medicine in Scotland.

The effect of all this extending and accumulating over half a century, may enable us to understand the greatness to which his reputation grew, both at home and abroad, and the honour in which his name is held among anatomists, and in the Edinburgh school.

ALEXANDER MONRO, *Tertius*.

When the third Monro was appointed to the Chair of Anatomy, on the petition of his father and the recommendation of all his father's colleagues, he was twenty-five years of age. The Council minute, too long to be quoted, is of date 14th November, 1795. The father, however, continued for eight years after this to give either the whole, or nearly the whole, of the course, not retiring till 1806-7, at the age of seventy-five, after which he lived for ten years, spending a peaceful old age on his estate of Craiglockhart, which he had purchased. As the third Monro continued Professor till 1846, when he retired from the chair, he was for about forty years sole Professor of Anatomy in the University.

Thus, the three Monros occupied the Chair of Anatomy for 125 years.

JOHN BELL.

We now come to the brothers John and Charles Bell.

John Bell had resolved to become a teacher of anatomy while yet a student. As this youth, remarkable for his keen eye, intelligent countenance, and small stature, sat among the crowd in Monro's class-room, it struck him that, although Monro was an excellent anatomist and teacher, the application of anatomy and surgery was neglected. He saw his opportunity, and took his resolution accordingly.

He began to lecture in 1786, in his twenty-fourth year, and taught till 1800—in all, fourteen years. For nearly twenty years thereafter he was the leading surgeon in Edinburgh and of Scotland. His lecture-room was to the east of old Surgeons' Hall, and was built by himself on ground feued from the College. His lectures were numerous attended, and rapidly brought him into notice. Although John Bell's name has come down to us chiefly as a surgeon, he was no mere surgical anatomist, as his writings show. The first and second volumes of his "Anatomy of the Human Body" appeared in 1793 and 1797, the third in 1802—after he had retired from teaching. Besides being anatomist and surgeon, John Bell aimed at being, and was, an accomplished man. He was a good classical scholar, extensively acquainted with ancient and modern literature, an accomplished musician, a skilful artist, and, as a lecturer, he was not only a ready and polished speaker, but his style was vivid beyond what had been hitherto known in the Edinburgh school. From causes which it would be easy to trace the ordinary Edinburgh tradition of John Bell has descended from the unfriendly side, and with no little exaggeration or distortion. To the unprejudiced student of his writings, the alleged exaggeration or romance of his narrative appear but the result of investing what is in ordinary hands a dull subject with the charms of that fine style and intense descriptive power of which Bell was so great a master. That he was deeply involved in controversy is true, but he was not the aggressor; and though nothing loth to accept Dr. Gregory's challenge, we can see that he was not a jealous, ill-tempered, or bitter man, but that he bore himself buoyantly through the long controversy, confident both in the position which he maintained and in his ability to defend it. The very step of his commencing to teach was regarded with hostility, which was in no way lessened by his brilliant success, or by the freedom with which he expressed his own opinions,

The position which John Bell exemplified and defended was, what no one will now dispute, that surgery must be based on anatomy and pathology—a doctrine for which there was at that time in Edinburgh neither acceptance nor toleration. A combination, led by Dr. James Gregory, Professor of Practice of Medicine, was formed against Bell; and the whole force of Gregory's wit, mixed with, to us, inconceivable personality and scurrility, was launched against Bell, not merely in pamphlets, but in volumes, and even in placards over the town. Thus attacked, Bell replied like a capable general, carrying the war into the enemy's camp; and while he did so with effect, his style, severe and personal though it is, is more dignified than that of Gregory's. Although from our point of view Gregory's plan for the service of the surgical hospital, at least as since improved upon, was the better, no one can understand what was at the root of that controversy without bearing in mind that the concealed object of Gregory's party was that John Bell, the only true surgeon in Edinburgh, might be excluded from the Infirmary.

On the, to him, adverse termination of the Infirmary dispute in 1800, which brought with it the loss of his connexion with the surgical hospital, he retired from teaching.

While teaching he had published his work on "Gunshot Wounds," and now, from 1801 to 1808, appeared his "Principles of Surgery," in three volumes, by which John Bell is best known—an undying book.

It is beyond my limits to follow Bell as a surgeon; but I may say shortly that he was the reformer of surgery in Edinburgh, or rather the father of it. He was not only a bold and original operator, but combined all the qualities, natural and acquired, of a great surgeon to an extraordinary degree.

His reputation was not confined to this country. When he visited the Continent, his professional brethren received him with the highest honour, and patients sought him at Paris and Rome. He died at Rome in 1820, in his fifty-seventh year.

I am informed by my colleague, Professor Pirrie, that when he visited Rome, in 1864, he saw the tombstone over Bell's grave in the English burying-ground. The inscription, which was nearly effaced, he caused to be renewed. It is a very modest one: "Here lies John Bell, surgeon, of Edinburgh. A man not uneminent in his profession."

SIR CHARLES BELL.

Charles Bell had not the same educational advantages as his brothers, his father, a Scotch Episcopal clergyman, having died when Charles was but five years of age. He used to say that his education was the example set him by his brothers. He was twelve years younger than John, who was his anatomical and surgical master, and five years younger than George Joseph, who was his attached friend through life, and died Professor of Scotch Law in the University in 1848.

Charles Bell's professional career was begun in Edinburgh, continued in London, and concluded in Edinburgh. Before leaving for London in 1804, when he was thirty years of age, he had taught anatomy for ten years, as we are told that when a comparative boy he assisted his brother John, and lectured to a class of several hundred students—John taking the surgery, Charles the anatomy.

Charles became a Fellow of this College in 1799, just before John retired from teaching, so that Charles could now conduct the school in his own right. His class amounted to ninety. During these ten years he published his "System of Dissections" in three volumes; "Engravings of the Arteries;" "Engravings of the Nerves;" "Engravings of the Brain;" and the third volume of his brother John's "Anatomy," in the work of which Charles had probably a considerable share. The greater part of his "Anatomy of Expression in Painting" was all written before he left Edinburgh.

He had a double reason for the step of removing to London. The party opposed to his brother John was influential in Edinburgh; and the Infirmary, by the supremacy of the same party, was closed against him. On the other hand, the example of John Hunter, who had died when Bell was a student, would be sure to have great influence on a mind like his. In short, he was both ambitious to go and glad to leave.

Even if time allowed, it would be out of place in this sketch to follow with the same detail the London part of Bell's career, which was long and eventful, extending over

thirty-two years. A very general notice of it must therefore suffice.

His first seven years in London was a period of comparative obscurity, and struggle with difficulties. In the ruinous old house in Leicester-street which he had taken to live and teach in, he had only three pupils to begin with; and it was years till he gathered forty. During this period he published his "Anatomy of Expression in Painting," and two surgical works, a "System of Operative Surgery," and on "Diseases of the Urethra." During the next fifteen years he occupied a prominent position among the teachers and surgeons of London, as teacher in the Hunterian School of Anatomy in Windmill-street which he had purchased from James Wilson, and as surgeon to the Middlesex Hospital, to which his clinical teaching brought pupils and financial prosperity. It will give some idea of the laborious and thoughtful life he must have led during these fifteen years, if I enumerate the works which he published, bearing in mind that he was at the same time conducting a school of anatomy and surgery, and acting as surgeon to the hospital. The works, in the order of their publication, were:—"Engravings of Morbid Parts;" on "Gunshot Wounds;" "Quarterly Reports of Cases," two volumes; "Engravings of the Nerves;" on "The Forces which Circulate the Blood;" on "The Nervous System," in the *Philosophical Transactions*; "Illustrations of the Great Operations of Surgery;" on "Diseases of the Urethra, Bladder, Prostate, and Rectum;" on "Injuries of the Spine and Thigh Bone;" and a new edition of John Bell's "Principles of Surgery."

When University College was about to be established, Bell, seeing that it would ruin his school, was induced to accept the Chair of Physiology in the new institution; but the arrangements proved so unsatisfactory to him that he resigned within a few days of the opening of the College. The Edinburgh College of Surgeons had meanwhile purchased his museum (I believe for £3000). This large museum was made partly by James Wilson, partly by Bell, the two parts being still distinguishable by means of Wilson's catalogue; and the whole forms a collection of human anatomy and surgical pathology second only to that of John Hunter.

During the remaining ten years of his London career, Bell did not teach, but was occupied in practice and in scientific writing. During this period his publications were—the seventh and last edition of "John and Charles Bell's Anatomy and Physiology," in three volumes; his "Animal Mechanics," in 1830; his greatest work, "The Nervous System of the Human Body;" his Bridgewater Treatise "On the Hand;" and "Illustrations of Paley's Natural Theology."

The Chair of Surgery in the University of Edinburgh was offered to Bell in 1836. After much doubt, he accepted it, writing to a friend at the time—"There is but one place where I can fulfil the object of my scientific labour, and that is in Edinburgh." The mistake here was that it was not a scientific but a practical Chair to which he was going; and that while he broke up a good practice, the growth of many years, in London, he was too far advanced in life to begin again. He lived but for five years after his return to Edinburgh, and during that time published two works on surgery—his "Institutes of Surgery," and "Practical Essays"—and a new edition of his "Anatomy of Expression." He still meditated a great work on the nervous system; but his diminished income retarded this, and death overtook him suddenly in 1842, in his sixty-eighth year.

In estimating the merit of Charles Bell, we must bear in mind, not merely what he achieved, but his early and long struggle with difficulties, and that he stood alone as a teacher, without the support of any institution. As an anatomist, his reputation rests on thirty years' teaching, and on his anatomical writings and engravings; while his "Anatomy of Expression in Painting" also established his reputation as an artist. His power as an artist, both in sketching and in painting, has probably never been equalled in the medical schools. It is in physiology, however, that Bell's name will go down to posterity. He had printed and circulated his views in 1810; but complained that they attracted no notice till, after repeating them in a paper at the Royal Society in 1821, he suddenly found himself famous, and raised, especially on the Continent, to even a higher position as a discoverer than Harvey.

It must be granted that Charles Bell was not rewarded as he deserved. His brethren in London were not to blame for

this; for they gave him, in 1824, all that was in their power to give, the temporary office of Professor of Anatomy and Surgery to the College of Surgeons. Nor was Edinburgh to blame for it; for the patrons of the University offered him the only suitable Chair which had become vacant during his career, though it brought him only £400 a year. The only appointment which was denied him, and denied him three times, was that of Professor of Anatomy to the Royal Academy in London, for which his claims were unrivalled. His income in London fluctuated between £1400 and £2400 a year—not a great income for a famous surgeon in London; and he might have made it more had he not chosen to give so much of his time to science. He was knighted in 1830, along with Brewster and Herschell, but received no pension from the State. Nothing was done to secure his services to science. It was his misfortune that no great anatomical position was within his reach, for that would have been his right place. Compare his career with that of the second Monro, the latter occupying a ready-made and splendid position from his boyhood; and yet Bell, notwithstanding all his difficulties, achieved more than Monro. Had Charles Bell, instead of the third Monro, been Professor of Anatomy, we may imagine, great as it was, how much greater his career would have been, how much more he might have done for science, and how much additional renown he would have brought to the Edinburgh school. As it is, Charles Bell's name must be placed in the first rank among those who have contributed to the progress of science, and to the relief of human suffering.

Professor Struthers proceeded to give interesting biographical sketches of Dr. Barclay, who had taught anatomy in Edinburgh from 1797 to 1825, who had a class at one time of about 300, and who had left behind him the largest museum ever formed by any one medical teacher in Edinburgh; Dr. Gordon, who was one of the best teachers and most valuable men of the Edinburgh School; Alexander Walker, William Cullen, Andrew Fyfe, and Dr. Knox, the direct successor of Dr. Barclay, who taught anatomy in Edinburgh for sixteen years, and whose lectures were so attractive that his class attained a number unprecedented even in Edinburgh. The lecturer proceeded to give a brief notice of the period between the end of Dr. Barclay's time and the retirement of the third Monro in 1846—twenty years—which he characterized as a period of much interest in the Edinburgh Anatomical School. We have only space for the following concluding general remarks on

THE CHARACTERISTICS OF THE EDINBURGH ANATOMICAL SCHOOL.

The characteristics of the Edinburgh Anatomical School had varied in different periods with the science of the time or with the characters of the men, who, though successors or rivals, were far from being copies of each other. The first Monro was not so much either kind of anatomist as all kinds in a primitive time. The second Monro was a descriptive anatomist in a more minute age, and his comparative anatomy was either special or physiological. John Bell originated the school of surgical anatomy. Charles Bell was teleological, and especially the artistic anatomist, and set the fashion in Edinburgh of anatomists publishing engravings. Barclay set the example of making the teaching of anatomy an occupation; his anatomy was descriptive and classic, and his comparative anatomy, though chiefly descriptive, was scientific enough to enable him to see and teach the outlines of homology. Gordon, again, was the physiological and minute anatomist, not only of the organs, but of the tissues, as far as the instruments of the day would carry him. Fyfe was the plodding practical demonstrator and text book writer, the provider of daily common anatomical food. Knox, lastly, was the morphological anatomist. Familiar with the work of the then brilliant French school—with the descriptions and inductions of Cuvier, and the then despised philosophy of Geoffroy St. Hilaire—Dr. Knox was able to invest human anatomy with a new interest. It was not to his great powers of satire, which could only make enemies, but to his having early mastered and appreciated the great facts and ideas of morphology, together with—as we may see by his writings—his wonderful command of the most felicitous language, that Dr. Knox's lectures owed their value and their attractiveness.

Dr. Knox also formed a considerable museum, which is now in my possession.

As the farther notice of this period would lead me to

speak of living men and of events which are fresh in the memory of many, the time has not nearly come for making it the subject of a historical sketch. When the history of this period is written, it will have to include a notice of an event important to this country as well as to the Edinburgh medical school—the passing of the Anatomy Act in 1830—and of the events which led the Legislature to see that it was for the public interest to legalise dissection. At some future time, I hope to be able to resume this sketch, so as to include this period.

During its delivery, the lecture was frequently applauded, and at the close, on the motion of Professor Syme, seconded by Professor Christison, a cordial vote of thanks was passed to Dr. Struthers for his careful and instructive history of the Edinburgh Anatomical School.

THE FELLOWSHIP OF THE COLLEGE OF SURGEONS OF ENGLAND.

CERTAIN modifications of the regulations respecting the Fellowship of the College of Surgeons have recently been promulgated, with which it will be well for those intending to present themselves for examination for that honour to make themselves acquainted. Since all now entering the medical profession are required to pass a preliminary examination in the subjects of a liberal education, it has been thought right to modify the preliminary examination for the Fellowship, and those who have already passed the preliminary examination for the Membership will only be required to pass in certain additional subjects instead of having to undergo an examination *de novo*. Those who have already passed higher examinations, or have taken higher degrees, will, of course, be exempt as heretofore. Several important modifications are about to be made in the professional requirements for the Fellowship, one of which is that only eight years of Membership will be hereafter required instead of twelve before a member of the College can be admitted for examination for the Fellowship without any preliminary examination whatever. Another alteration, which will be most welcome to the provincial schools and those educated at them, is that the invidious distinction between attendance at London and provincial hospitals is proposed to be done away with, and that for the future certificates from all recognized hospitals and schools will be as available for the Fellowship as the Membership. Certain additional requirements will be found in the new regulations, and amongst them attendance upon a course of Practical Chemistry will be requisite as well as a certificate of having attended a course of lectures upon operative surgery, and of having performed operations on the dead body. Hitherto operations on the dead body have formed a part of the examination, but it is a manifest advance to require due instruction in such an important subject. It may be well to remind those now students that they will be required to produce certificates of having attended lectures on anatomy and physiology and of having dissected during three winter sessions before they can be admitted to the Fellowship examination, whereas they only require two courses on each subject for the Membership; and we would, therefore, strongly advise their taking out this additional attendance in their third year, so that they may not be hindered from presenting themselves for the Fellowship later in life. It has hitherto been necessary that six years should be spent in some recognized hospital and medical school, and this will still hold good with respect to new members of the College. Those already members of the College, however, will only have to attend for two years in addition to the time required for the Membership diploma—viz., two years and a half (three winters and two summers); and those, therefore, whose professional engagements prevent their remaining the full period at a medical school at one time will thus have less difficulty in making up the extra attendance.

It is intended to separate the first or anatomical and physiological examination from the surgical or second examination more than has hitherto been done, and to permit the student to present himself for the former at the end of his third year. This will probably be thought a boon by many, but we must say we doubt the propriety of encouraging the tendency which is so prevalent in the present day to make the student regard anatomical and physiological knowledge not so much as sciences to guide him in his practice in after life, as subjects to be crammed for the nonce, and to be utterly forgotten the

moment an examination in them is passed. Our great surgeons were not men who threw aside their scalpels at the end of their third year of study, and never investigated anatomical and physiological data again. In the scheme for the second or professional examination we find one subject for sincere congratulation, and it is that it "shall include pathology, therapeutics, surgery, the examination of patients, and operations on the dead body." We are glad to find the Council of the College thus yielding to the force of public opinion, although it has always hitherto been maintained that the Charter did not permit of such an innovation. Perhaps, as it has been found possible to extend the examination for the Fellowship in this direction, it may before long be found equally possible to test the knowledge of candidates for the Membership in the same manner—the only manner, in fact, in which surgical knowledge can be properly tested. Taken as a whole, the new regulations for the Fellowship may be regarded as evidence of progress within the College walls, and we trust that from year to year, as the general feeling of the profession makes itself more and more heard, the rate of progress will be much increased.—*Lancet*.

THE CHOLERA ON BOARD THE *HELVETIA*.

A SUPPLEMENT to the *London Gazette*, containing an order in council, which, after reciting the powers conferred on her Majesty's Privy Council for preventing the spread of infectious diseases, says:—"Whereas a certain vessel, named the *Helvetia*, having a certain infectious disease on board, that is to say, the Asiatic cholera, has arrived, or is expected to arrive, at Liverpool; and whereas it is expedient to cut off all communication between persons on board that vessel infected with that disease and the rest of her Majesty's subjects: now, therefore, in exercise of the powers conferred upon them, the lords of the council do order, and it is hereby ordered: 1. That in case of such vessel arriving at Liverpool, having such disease on board, no person shall land from such vessel for the space of three clear days after her arrival at Liverpool without the permission of the Mayor of Liverpool. 2. The Mayor of Liverpool shall forthwith cause all persons on board the said vessel to be examined by a physician or surgeon, and shall permit all such persons to land immediately who shall be certified by such physician or surgeon to be free from such disease. 3. All persons certified by such physician or surgeon to be affected with symptoms of such disease shall be removed, if their condition admits of it, to some hospital or place to be designated for such purpose by the Mayor of Liverpool; and no person so removed shall quit such hospital or place until some physician or surgeon shall have certified that such person is free from the said disease. 4. All persons offending against this order shall be liable to such penalties as are imposed by the said act of parliament upon persons offending against the provisions thereof."

A special meeting of the health committee was held for the purpose of taking into consideration the best steps to be adopted for the prevention of the spread of cholera in this town, consequent upon the return of the emigrant ship *Helvetia*, on board which that disease had broken out. The meeting was attended by Dr. Buchanan, who, at the request of the Mayor, was dispatched from London last night; Mr. Fletcher, chairman of the Steam Navigation Company, to whom the *Helvetia* belongs; Mr. McAllister, the manager for the company; Mr. Hagger, the clerk to the select vestry; and Captain Prior, the emigration agent. The Mayor stated that he should not allow any of the sick passengers of the *Helvetia* to land on the arrival of that ship; and Dr. Buchanan having stated that the best course to adopt would be to have the sick passengers transferred to two other ships, and the *Helvetia* thoroughly cleansed before resuming her voyage, Mr. Fletcher stated that the company had two vessels for this purpose at their disposal, and that as soon as the *Helvetia* arrived those measures would be carried out. In answer to a question he stated that the *Helvetia* was measured to carry 1080 passengers, but that at the present time there were only 817 on board. He had been informed that the *Helvetia* was now lying off the bar, and would probably arrive about one o'clock this afternoon. After considerable discussion a sub-committee of the health committee was appointed to wait upon the select vestry to carry out such arrangements as might be requisite under existing circumstances connected with the present outbreak of cholera on board the *Helvetia*

We are informed that no fresh cases of cholera have broken out on board the *Helvetia*; in fact, it is hoped that when the vessel arrives the sickness will be of so slight a character as only to cause a brief detention of the vessel in the river. Mr. Wilson, the inspector, informed the health committee that the German lodging-houses in Liverpool were being visited every day and every night. Last night there were only very few lodgers in those houses, the majority having left for America within the last few days. A telegram had been forwarded to Rotterdam, requesting that no more emigrants should be sent to this port for some time. There was no sickness among the German inhabitants of the lodging-houses, all of which were very clean.—*Liverpool Post*.

It now appears that the removal of the German emigrants from the *Helvetia* to the dépôt at Birkenhead is likely to prove an impolitic step. The cholera has appeared among them and seems likely to spread. One case is in the workhouse—that of the father of the child who died last week. Three deaths had occurred on Tuesday night from cholera on board the hospital ship *Jesse Munn*, and there have since been two more. At the time of the last death there were seven other patients in various stages of the disease on board the *Jesse Munn*. The bodies were removed for interment at the Walton Cemetery immediately after death. The town continues to be flooded with fresh arrivals of Germans, who, it is presumed, have passed the medical examination at Hull. So great was the demand on the lodging-houses, that late on Tuesday night, Dr. Trench, the medical officer of health, sent a body of 200 Germans, men and women, to the workhouse, with a note to the governor, asking that he would accommodate them for the night. The governor was in a dilemma, as the men were not paupers, and, in answer to his questions, they stated that they had contracted for respectable lodgings, which they were then quite able to pay for, but could not obtain accommodation. He was also influenced by the fear that by admitting them he might spread infection among the inmates. Having consulted two members of the select vestry, he finally resolved to place them in the large waiting-room adjoining the relief department. They were there supplied with coffee and bread, and remained for the night. Yesterday morning they again went into the town. Yesterday further assistance was sent, in the shape of bedding and nurses, to the *Jesse Munn*, from the workhouse. Application was also made by the medical officer at Birkenhead, backed by a letter from Dr. Trench, for nurses, and they were sent. It is stated that the officers and crew of the *Helvetia* and the hospital ship are almost paralysed by fear. The fumigation of the *Helvetia* proceeds rapidly. The latest information is that so had are many of the patients on board the *Jesse Munn* that a dozen coffins have been ordered to be in readiness. It is questionable whether the landing of the bodies for burial is not in direct contravention of the Order in Council, which provides that all bodies of those dying from cholera shall be taken out to sea, and, being loaded, shall there be buried. A German lodging-house-keeper was yesterday fined for overcrowding.—*Times*.

QUARANTINE AND CHOLERA.

The supplement to the *London Gazette* publishes the following order issued by the authority of the Privy Council. After quoting the Act passed in the sixth year of George IV., cap. 78, the order states that:—

"And whereas a certain infectious disease,—that is to say, Asiatic cholera—is prevalent in certain foreign parts; and whereas it is expedient to cut off all communication between persons on board any vessel infected with that disease and the rest of Her Majesty's subjects:—

"Now, therefore, in exercise of the powers conferred upon them by the above-quoted section of the said Act, the Lords of the Council do order, and it is hereby ordered—

"1. That in case of any vessel arriving in any port of the United Kingdom having such disease on board, no person shall land from such vessel for the space of three clear days after her arrival, without the permission of the local authority.

"2. The local authority shall forthwith cause all persons on board the said vessel to be examined by a physician or surgeon, and shall permit all such persons to land immediately who shall be certified by such physician or surgeon to be free from such disease.

"3. All persons certified by such physician or surgeon to be affected with symptoms of such disease shall be removed, if their condition admits of it, to some hospital or place to be designated for such purpose by the local authority; and no person so removed shall quit such hospital or place until some physician or surgeon shall have certified that such person is free from the said disease.

"4. In the event of any death from cholera taking place on board of such vessel, the body shall be taken out to sea, and committed to the deep, properly loaded, to prevent its rising.

"5. The clothing and bedding of all persons who shall have died or had an attack of cholera on board such vessel during her voyage, either at any foreign port or on shore at such port, or on her passage to the United Kingdom, shall be disinfected, or (if necessary) destroyed under the direction of an officer of the Customs.

"6. The local authority for the purposes of this order shall be the Local Board of Health, where there is such local board; and in any corporation where there is no such local board, the local authority shall be the Town Council of such corporation.

"7. All persons offending against this order shall be liable to such penalties as are imposed by the said Act of Parliament upon persons offending against the provisions thereof.

"ARTHUR HELPS."

PROFESSOR HUXLEY ON THE RELATION OF PHYSICAL SCIENCE TO MEDICAL SCIENCE AND MEDICAL EDUCATION.

ON Tuesday, May 1st, the annual distribution of prizes at St. Mary's Hospital Medical School took place, on the opening of the summer session. The Dean read the annual report, which alluded especially to the institution of practical microscope classes for the study of normal histology under Dr. H. Lawson, and of pathology and morbid histology under Dr. Charlton Bastian; the building of a new wing of the hospital, which would include a children's hospital; and the entry of new students for the year, which had amounted to thirty-three.

Professor HUXLEY said that he had hardly clearly apprehended at first that a certain gravamen attached to the honour of presiding, in the shape of an address. After a brief introduction, he proceeded to speak of the relations of the physical sciences to medicine and medical education. He defined the object of the science of medicine as being to ascertain the nature of the disability which a diseased person labours under, and the means by which that disability can be removed; and, correlatively, the art of medicine as the skilful use of all those means by which we can ascertain what is the matter with the diseased man and their application to his cure. One great division of these means was derived from, or in its use dependent upon, the physical sciences. The microscope, the ophthalmoscope, the stethoscope, chemical tests, and the other great and familiar means of diagnosis, were all physical appliances. Further than that, every liberally educated medical man should surely know something about the nature of the bodies which he is constantly employing. He should certainly, as a man of liberal education, know enough of botany and zoology to be on even terms with laymen, and give safe opinions and safe answers concerning the animal and vegetable substances which he uses constantly. He was quite prepared to admit, and indeed had always had a strong conviction, that there was something absolutely preposterous in the volume and bulk to which, for example, some of our treatises on materia medica extend, and the enormous quantity of absolutely irrelevant matter. He was not one who would take the student through the length and breadth of physical optics because there are particular substances used in medicine which change the polarization of light or exhibit the phenomenon of fluorescence. This was the Scylla; total ignorance was the Charybdis.

But there was a more important aspect of the matter; the relation in which the science of medicine stands to physical science in general. The scientific man makes use of the data of physical science for the purpose of reasoning

out the exact conditions of the case which he has before him, and for the purpose of applying the precise measures which are adapted to meet that case. Having this conception of what is meant by scientific medicine, what has to be done in medicine before we shall reach this condition? For, although looking about us to surgical practice particularly, and perhaps in some few cases in medicine, it would be possible to adduce instances of what he should call perfect medical science; that is to say, where you have a complete knowledge of the lesion, and a complete knowledge of the conditions required to restore that lesion; yet these were among the rare cases presented to the physician or surgeon. And, in the majority of cases, we had no such complete knowledge. There was a wicked and libellous old story, in which it was said, by way of illustration of medical practice, that in a diseased man Nature and disease are as two men fighting; and that the doctor is a blind man who comes with a big stick, and hits hard, and sometimes hits the disease and sometimes hits Nature. If he might modify the story, he should say that, in these days, the physician is not blind, but, on the contrary, is a remarkably sharp-sighted, acute, painstaking, and conscientious person; but that he finds himself in a very dim twilight; and that, having ascertained that the light is very uncertain and very apt to vary, he rather, as a conscientious person, abstains, as far as possible, from using his club, and confines himself to what, if he might say so without offence to that company, was known as the part of a judicious bottle-holder—ready to pick up Nature whenever she gets exhausted and bring her up to time. That he took to be a fair description of the modern practice of physic; and no doubt it indicated a beneficial change satisfactory to patient and to the physician, who feels that his club is not stained by innocent blood. But this was not final; and we must all look forward to the physician attaining as clear a mental vision of the condition of a diseased part, and the means of relieving it, as the surgeon has in the plainest kind of surgery. What the physician wants is more light. He wants a better light upon the arena of the fight, so that he may be able to remove the obstacles in the way of Nature, and may be able, as occasion offers, to deal his opponent a severe blow, without the chance of doing her an injury. That light must come from the cultivation and improvement and the refinement in every way of those sciences which furnish us with the data for deduction—the abstract physical sciences of anatomy, physiology, chemistry, physics, and so forth.

Upon a clear appreciation of this all our theories of medical education must eventually turn. Let it be granted, then, as he believed it must be, that a thorough grounding in physical science was the basis of all medical education. How was this attainable? One of the most experienced surgeons in these islands had raised his voice against the immense indigestible mass of information crammed into the medical student now in the course of three years. Coming without a scintilla of a notion of anything about science, he was expected to learn physics, natural philosophy, chemistry, botany, zoology, with comparative anatomy, human anatomy, histology, pathology, therapeutics, medicine, surgery, dietetics, jurisprudence. The thing was absurd. You might make a sort of intellectual *foie gras* of him; but you could not give him information of the kind and scope which he ought to have in that time, and with the existing methods. They might be taught to pass examinations. He was going to say he would teach a dog to pass an examination, or at least nine-tenths of the examinations that men pass through; but they would not acquire a knowledge of the facts from their own observation, and the only knowledge that is of the smallest use. The practical and purely professional subjects alone must more than fully occupy every minute of the three years of study. What, then, was his meaning in dwelling on the enormous importance of physical science to students of medicine? He held that all this acquaintance with the principles of physics and chemistry and biology

ought to have been acquired in the course of their general education. If those who regulate education in this country had the smallest conception of what their real duties are, or of what the purposes of mankind and the conditions of its progress at the present time were, they would give that knowledge; and those who wish to improve medical education must, to his mind, throw themselves into that object; they must compel those who give us primary education to make physical science a very large constituent portion of that education. It was the duty of every man to lift up his voice against the scandalous perversion of human time and human ability under the system of gerund-grinding which now prevailed at schools. And, for one particular purpose of medical training, it was the duty of every one of us who had that cause at heart to endeavour to exercise such an influence that the medical teacher shall not have to commence upon a mere *tabula rasa*, but that the young men who come up for medical education shall have been accustomed to acquaint themselves with chemical formulæ and chemical reactions; shall have learnt the great distinguishing features of the different forms of life, and the broad facts of physiology, the elementary outlines of which might (he spoke from experience, be taught perfectly well to boys of ten years old. How much easier the task would then be, not only for the learner, but for the teacher; and how vastly greater would be the stride made by every man towards that great goal already indicated, the establishment of a scientific medicine.—*British Medical Journal*.

THE ULSTER MEDICAL SOCIETY.

THE annual meeting of the above long-established and influential body of medical practitioners of the Province of Ulster was held in their Library Room, in the Belfast General Hospital, on Saturday, at three o'clock p.m. Dr. Moore (James), the outgoing president, occupied the chair. The appointment, by ballot, of office-bearers for the ensuing year being the first business on the list of the day's proceedings, the following were balloted for and declared duly elected, viz:—

President—Dr. Drennan. Town Vice Presidents—Dr. H. S. Fergusson and Dr. William MacCormac. Country Vice-Presidents—Dr. Scott, J.P., Aughnacloy; and Dr. Graves, Cookstown. Council—Doctors Stewart, Patterson, McCrea, Whitaker, Murney, J.P.; and Rea. Treasurer—Professor Cuming, M.D. Joint Secretaries—Dr. John Moore and Surgeon Robert H. Newett.

Dr. Moore then addressed the meeting before resigning the chair, when he shortly reviewed some of the more salient occurrences during his year of office, observing that at the fortnightly meetings of the Society there were always most interesting pathological specimens and cases brought forward, which underwent the fullest and freest discussion; nor could such be over-estimated in a practical point of view, and this not only to the members themselves, but especially so to the medical students who had the privilege of being present at those discussions, and so afforded the benefit of the matured skill and judgment of their seniors. He then referred to the great value of the circulation of the several medical periodicals of the day amongst the members, which was one of the many advantages of their body, and which it was so desirable should be carried on with the strictest attention and regularity, their due circulation being, in point of fact, the back-bone, he might say, of the Society. The subject of "increase of wages" was then touched upon. All skilled and unskilled classes in the community were now, he observed, demanding and obtaining increased remuneration for their time and skill, but the hardest worked and most expensive and responsible of all professions and callings, as theirs confessedly was, continued to be the worst remunerated as usual. But what must be considered a most serious injustice to their junior medical brethren, and also to the ratepayers themselves, was the well-known fact of tradesmen and mechanics, earning from two to three pounds a week, obtaining for their wives and families advice and medicine from the dispensaries, who were well able to pay for both. The Dispensary Medical men and Board of Guardians should resolutely set their faces against the continuance of so great an abuse as this palpably was, the time having fully come

for their doing so. The office of coroner for the Belfast district, so legitimately belonging to their profession, he stated, had since their last annual meeting become vacant, upon which a special meeting of their Society had been called by him to consider the propriety of supporting one of their brethren to fill it, and which had been unanimously resolved upon; but subsequently it was discovered that the Town Council had in their own hands the power of appointing a Coroner for the borough of Belfast exclusively, and who had appointed a most excellent and judicious one in the person of Dr. Dill. Dr. Campbell of Lisburn, another equally deserving and well-qualified practitioner, having been elected by the Parliamentary voters for the other portion of the district, so that thus two of their body were now exercising that important office in this locality, which was a great point gained for their profession. During the past year two of their Society, he sincerely regretted to say, had been removed by death from amongst them—Professor Fergusson and Dr. Hunter—both gentlemen in the truest sense of the term, and of highly cultivated intellects, and both deeply mourned for as men and as brethren for their always honourable and exemplary conduct and great ability as medical practitioners. He might also name Dr. Catherwood of Donaghadee, who had lately paid the last debt of nature, and who was a truly Christian and worthy man. Two of their Society had during the year taken their leave of Belfast, and removed to practise elsewhere—he alluded to Drs. Strong and Hanna, the former to Dublin, and the latter to one of the distant colonies. The "Royal Medical Benevolent Fund Society of Ireland" was then brought under notice, with the view of impressing the obligation which devolved upon each member of the profession of subscribing to it, so as to enable its disinterested managers to accomplish the largest amount of good possible, but which could not be done unless each and all gave that most excellent Society their countenance and best support, and of which it was so eminently deserving. The President, after referring to some other matters of detail, concluded his very appropriate and well-received address by observing that, in relinquishing the chair he then occupied, it was with the greatest gratification he handed it over to Dr. Drennan, who not being present, he might the more freely speak of his exalted worth both as a citizen and a member of their profession, deeply learned, and of the most sterling principles; and also to make the passing remark that the new president's father, the celebrated Dr. Drennan, obtained for Belfast the title of the "Athens of Ireland" by reason of his distinguished literary attainments. Their president, then, for the ensuing year might truly be said to be "the worthy son of a most worthy sire." One more remark he had to make which was his being enabled to announce that during the ensuing year a large infusion of new blood might be expected into the Society, several of their younger brethren having recently intimated to him their intention of joining it.

On the motion of Professor Cuming, Dr. Stewart took the second chair, when the worthy Professor expressed what great pleasure it had afforded him—the excellent address with which they had been favoured by the outgoing president, and the feeling and entirely appropriate manner in which he had alluded to the great loss the Society had sustained by the deaths of Professor Fergusson and Dr. Hunter, than whom there could not have been more honourable men, or more highly qualified practitioners. He (Professor Cuming) considered the Society was much indebted to Dr. Moore for the great attention he had paid to its affairs during his year of office, and the many valuable and interesting cases he had submitted for discussion at their meetings. He begged, accordingly, to move, "That the best thanks of the meeting be given to their late president for the able and zealous manner in which he had fulfilled his official duties, and his readiness at all times to advance the Society's best interests."

Dr. Patterson said he had much pleasure in seconding Professor Cuming's motion, and that he could fully endorse all he had so well and eloquently said as to the manner in which Dr. Moore's duties, as their president, had been discharged.

The motion having been put from the chair, accompanied by a few remarks of the chairman in confirmation of what had been stated by the mover and seconder, it was passed by acclamation; and, thanks having been returned by Dr. Moore, the meeting separated, much gratified with the pleasing nature of the day's proceedings.

MEDICAL TRIALS.**COURT OF EXCHEQUER.**

(Sittings at Nisi Prius, before Mr. Baron CHANNELL and a Common Jury.)

RUDMAN v. ARMSTRONG AND ANOTHER.

THIS was an action against two medical men for the unskilful and negligent treatment of the plaintiff, whereby she was greatly injured in health and constitution, underwent great suffering, and was unable to work and gain her livelihood. The defendants pleaded not guilty.

Mr. Pearce was counsel for the plaintiff; and Mr. Serjeant Robinson and Mr. Inderwick for the defendants.

The defendants were Dr. John Armstrong, who has practised for thirty-three years at Gravesend, and his son, Mr. John C. Armstrong, who is in partnership with his father, and the plaintiff, Sophia Emily Rudman, was between 18 and 19 years of age, and the daughter of Thomas Rudman, a boot and shoemaker in an humble way, living in the neighbourhood of Hackney. The case for the plaintiff was briefly as follows:—In 1864 her father kept a shop in Gravesend, and lived in lodgings in Edwin-street, in that town. She had always resided with her parents, had been employed in shoe-binding, and was represented to have invariably enjoyed good health. On a Sunday in November in that year, while walking across the room, she fell down, and, according to her own account, without any apparent cause, and hurt her knee. The limb swelled and grew rapidly worse, and she became an out-patient of the Gravesend Dispensary, of which the defendants are two of the honorary surgeons. She attended regularly about once a week, and was seen by one or the other of the defendants, who gave her advice and prescribed medicines, which were made up at another branch of the institution upon the payment of a fee of a penny on each occasion. She ceased going to the dispensary by the beginning of June, at which time she was said to be in a weaker state of health. Afterwards the plaintiff's father engaged Dr. Armstrong to professionally attend her at her own home, and he continued to do so until June, 1865. Notwithstanding his treatment she grew worse, and showed all the symptoms of excessive salivation by mercury. Her mouth became so sore, and her teeth so loose, that she could only eat with difficulty; her nails were affected, and some came off, while sores broke out on her hands and feet. It was also stated that her hands and feet were contracted by the operation of the mercury, which it was alleged had been improperly administered. When the plaintiff's solicitor wrote to the defendants threatening an action they denied that the girl had been improperly treated, and expressed their readiness to contest the point, sending their claim for professional services, which amounted to £8 18s., for that purpose.

The plaintiff was carried into court in an apparently helpless condition, and briefly examined. Afterwards, on the suggestion of the learned judge, she was taken into his private room, and examined in private by four medical men, two representing each side.

Two surgeons who had treated the plaintiff since she left the defendants, Mr. Bonny of Greenhithe, and Mr. Vinal of Hackney, were called on her behalf and gave evidence as to the symptoms which she exhibited. The former gentleman said that these symptoms might have been produced by the excessive use of mercury, but Mr. Vinal expressed some doubts upon the point.

In the course of the trial a box of ointment, which the plaintiff's mother said had been prescribed by the defendants, was produced. The ointment was to be applied twice a day to the knee, and she deposed that whenever this was used by the plaintiff it produced suffering and made her worse. The composition was proved to be ordinary mercurial ointment. The defence was that the defendants treated the plaintiff according to the best of their knowledge, skill, and judgment as medical men; but that she was of a weakly constitution, and the nature of her occupation and the circumstances under which she lived, the whole family residing in two rooms, and probably not having a sufficient quantity of nourishing food for one in her condition, retarded her recovery. It was also said that if mercury was used it was only after all other remedies had failed, and then only in the proper manner and in the right quantity. They stated that

they heard no complaints from the girl or her parents as to the mode in which they had been treating her until they received the lawyer's letter, and there was a suggestion that the action was only a solicitor's one to recover costs.

Mr. J. C. Armstrong said he saw so many patients at the dispensary that he could not recollect the particular nature of the prescriptions he wrote, but he gave the plaintiff nothing to produce undue salivation. He rarely used mercury in his practice, and, as a rule, he was opposed to its use. He had no knowledge of the box of ointment and was inclined to think that he had never prescribed it.

Dr. Armstrong (the father) said, that after having tried fairly and honestly the effect of medicine on the plaintiff, without making a cure, he came to the conclusion that the impediment to her cure was the want of proper food, fresh air, and exercise. He added, that the atmosphere of the room in which he always saw her was very impure and offensive, and that no person suffering from any complaint, who lived in it, was likely to get better. He seldom resorted to mercury, and his son used less. The witness said the whole of his prescriptions for the plaintiff were in court.

Mr. Solly of St. Thomas's Hospital, who had examined the plaintiff, deposed that he did not discover the slightest possible trace of salivation by mercury upon her. He also expressed a positive opinion that her knee was free from disease, and that she had the perfect use of it. He thought she could walk from the court into the hall, but with this qualification—that, owing to her weak state from long confinement, she might perhaps require a little assistance. With regard to the use of mercury in cases of disease of the joints, he said it was often employed with effect when iodine had failed. Sometimes the appearances of salivation presented themselves without the use of mercury, particularly when iodine had been taken. He was quite certain the plaintiff could walk into the hall, or else his experience of forty years went for nothing.

The trial occupied nearly the whole of two days, and when it was resumed this morning,

The jury, after consulting together, intimated that they were already agreed that their verdict should be for the defendants.

Mr. Pearce said that after that expression of opinion by the jury he did not think it would be respectful to them to address them on the part of the plaintiff.

Mr. Serjeant Robinson said he had several other professional men to prove that the plaintiff had been properly treated by the defendants.

Mr. Baron Channell expressed his entire concurrence with the jury in their verdict.

Verdict for the defendants.

Parliamentary Intelligence.**HOUSE OF COMMONS.—MAY 9.****VETERINARY SURGEONS BILL.**

Mr. HOLLAND moved the second reading of this bill. The object of this bill was to prevent unqualified persons from holding out to the public that they were members of the Royal College of Veterinary Surgeons when, in point of fact, they were not. There were at present 1244 persons practising as veterinary surgeons under the assumption that they had obtained diplomas. There were 1189 farriers who were acting as such who had no diplomas. Altogether there were 2433 persons practising without any diploma, against 1144 regularly qualified practitioners. It was essential that an improved status should be given to veterinary surgeons, and he felt that a simple bill requiring that every veterinary surgeon should be *bona fide* a member of the Royal College of Veterinary Surgeons would be of great value at the present time. He proposed that any person who fraudulently held out to the public that he was a veterinary surgeon should be liable on summary conviction to a penalty of not exceeding £5 and not less than £2. The bill, however, was not to affect persons who should have assumed the title six months previous to the passing of the bill.

Sir J. JERVOISE was at a loss to understand why a man should be prevented from assuming the title of veterinary

surgeon. He suggested that when in committee some alteration should be made in its provisions, to make them apply to those who held themselves out as members of the Royal College of Veterinary Surgeons.

Mr. NEWDEGATE said he believed this bill would be acceptable as a means of promoting the education of the profession. He had been many years one of the governors of the Royal College of Veterinary Surgeons, and he could assure the house that great exertions had been made by the college to raise the scale of education for veterinary surgeons and no obstacle had interposed to render their attempts ineffectual to a certain degree more than that the education after it was completed brought with it no distinction (hear, hear), because the uneducated as well as the educated appeared before the public with equal claims so far as appearances were concerned.

Mr. BRUCE said it was not his intention to oppose this stage of the bill, but it would be necessary to make some amendments in it in committee. In the case of the chemists and druggists and the pharmaceutical chemists, it was made an offence to assume the name of pharmaceutical chemist, and if with regard to veterinary surgeons they added something to the title, such as Royal College, &c., it might form a reasonable proposition that for the infringement of the title the person so offending should be liable to a penalty.—The bill was then read a second time.

MAY 4TH.

QUARANTINE IN CORK HARBOUR.

Sir G. GREY, in answer to a question, said Government were of opinion that whatever precautions were taken against cholera in this country should be taken without delay. In July, 1865, when the disease was reported to be prevalent at Alexandria, the Privy Council forwarded to the authorities of all the ports in Great Britain and Ireland printed memoranda of the means to be adopted to prevent the spread of the disease. At Liverpool an hospital ship was provided for cholera patients; but competent persons entertained a doubt whether a ship was the best hospital to provide in such an emergency—whether it was not much better to make provision for the reception of patients on shore. The hospital ship in Queenstown Harbour was maintained at a cost of £300 a year; but as during six years it was only once used—and on that occasion for a few days only—it was thought desirable to discontinue its service. In case, however, of any urgent necessity the Admiralty would place a ship at the disposal of the municipal authorities. With regard to any general arrangements of the system of quarantine, in consequence of information received from Liverpool by telegram yesterday, and confirmed by letter to-day, the Privy Council had met that afternoon and considered the question of giving to the municipal authorities additional powers with a view of dealing with ships which might arrive at any one of the ports of England with cholera on board.

GAS-WORKS NEAR VICTORIA PARK.

Mr. COWPER said, in reply to Lord J. Manners, that by the standing orders of that House any Bill which authorised the erection of gas-works within 300 yards of any house, required that notice of such erection should be given to the owners and occupiers of such houses. But that did not apply to the present case, because the Imperial Gas-works Bill contained a clause prohibiting the erection of any works within 300 yards of any part of Victoria Park. He was, however, of opinion that no great grounds of complaint could be made even if gas works were erected within 300 yards of any buildings, provided they were properly and prudently conducted (cries of "oh, oh!"). The nuisance arising from gas works, being entirely occasioned by the refuse of those works, could be remedied by the insertion of a clause requiring the company to remove the refuse and to prevent the accumulation of such refuse (laughter). He should feel it his duty to ask the promoters of the Bill to insert in their Bill such clauses as might be necessary for the protection of the public health.

MEDICAL OFFICERS OF THE GUARDS.

Sir R. ANSTRUTHER brought under the notice of the House a grievance of the medical officers of the Guards, entailed by an order of 1860, recently brought to light, regulating their promotion, and moved for papers. The motion was seconded by Lord H. Percy, and the Marquis of Hartington, in granting the papers, controverted some of the statements of the mover. General Peel declared the subject to be unfit for the House of Commons, and deprecated all such interferences with the discipline of the army, and the discussion, which was highly professional in its character, was continued by Dr. Brady and others. Sir R. Anstruther begged very respectfully to submit to the noble marquis and the Commander-in-Chief, not as a question of right but of justice, that the action of the warrant should simply not be retrospective. The assistant-surgeons of the brigade of Guards did not ask that the warrant should be repealed. They did not say that it was a bad warrant, and they would even admit that it might possibly be a good one. What they asked, however, was that it might not have retrospective action. The Marquis of Hartington replied, "I shall not be able to advise the Commander-in-Chief to postpone the operation of the warrant of 1858 with regard to assistant-surgeons; but rather that matters shall be left upon the footing on which they were placed in 1860." He agreed, however, to produce the warrant of 1860. General Peel said, "Nobody regrets more than I do that the warrant of 1858 was departed from. I think it is a very bad thing for the service; but I never doubted the power of the Secretary of State to make the alteration. In the House and out of the House I have always done everything I could for the medical officers of the army, and I am happy to say that in the Guards great good feeling exists between the combatant officers and the assistant-surgeons and surgeons of the regiment. I only wish that similar good feeling had been universal throughout the army, and in that case, I believe, there would have been no necessity for altering the warrant."

MEDICAL OFFICERS IN THE ARMY AND NAVY.

On Tuesday week, Colonel NORTH asked whether it was the intention of Government to carry out the recommendations, as regards increased pay, &c., of the Committee which was appointed to inquire into and report upon the grievances of medical officers of the army and navy; and if there was any objection to lay the report upon the table of the House.

The Marquis of HARTINGTON said that the recommendation of the Committee involved not only a considerable increase of pay to medical officers in both services, but questions of the expediency of placing the medical officers of the two services on a different footing. The recommendations of the Committee were receiving due attention; and, as soon as a definite decision was arrived at, he would communicate the result to the honourable member. He did not, however, think that it would be expedient to lay the report asked for upon the table just now.

WATER-SUPPLY OF THE METROPOLIS.

Mr. HANKEY, in moving for a committee to inquire into the water-supply of the metropolis, observed that, though the quantity of water pumped into London was adequate, the system of distribution was defective, and pointed out that, while in all other great towns the supply was constant, in London it was intermittent, at most for two hours a day, thus necessitating a storage capacity for at least 100,000,000 gallons. A proper system of continuous supply by means of service pipes, he maintained, besides other advantages, would promote economy, inasmuch as a daily supply of 45,000,000 gallons, or fifteen gallons per head, would then be sufficient. He argued, with regard to the future supply that, if, as was anticipated, the population of the metropolis increased by another million and a half in the next twenty years, the present sources of supply, chiefly the Thames and the New River Company, would

become totally inadequate, and mentioned a scheme which had been published for drawing a supply from a mountain district beyond Shrewsbury.

Mr. AYRTON reminded the House that this question of cisterns as opposed to continuous supply had been exhaustively discussed and finally settled some years ago. As no tangible cause of complaint with the present system had been alleged, he pressed the House not to enter on an inquiry which it had no means of conducting to a satisfactory conclusion.

Mr. WATKIN and Mr. Alderman LUSK concurred in thinking that a pressing case for inquiry had been made out.

Sir G. GREY, as no complaint had been made of the quantity and quality of the water-supply, thought it unadvisable to appoint a committee at this period of the Session, and recommended the withdrawal of the motion,—a suggestion which was accepted by Mr. Hankey.

IMPERIAL GAS COMPANY BILL.

This Bill was disposed of after a short debate.

Mr. TITE moved its rejection, and the House turning a deaf ear to the undertaking of Mr. Staniland (who had charge of it) to strike out all the clauses relating to the erection of gasworks near the Victoria Park, he ultimately withdrew it.

CHARING-CROSS HOSPITAL.

A VACANCY has occurred in the Medical Staff of this Hospital, and we understand that the office of Assistant Physician will be competed for by Dr. Tilbury Fox and Dr. Julius Pollock. It is anticipated that Dr. Fox will probably succeed to the vacancy. He has already achieved a most creditable reputation as an original and laborious writer. His researches on skin diseases have been favourably noticed in our columns, and his contributions on other branches of medicine and surgery are well known to the readers of the periodical literature of the profession. Dr. Pollock is son of the Lord Chief Baron, and is also highly esteemed, though he has yet to win by his pen a public position equal to that of Dr. Fox.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 8th inst. :—

Barlow, Charles, Stalybridge.
Cooper, William Wightman, Nottingham.
Coxwell, John Edward Grinfield, Woburn-place.
Cox, William Alfred, Bath.
Fielding, James Robert, Alfreton, Derbyshire.
Gell, Thomas Silvester, Stafford.
Hembrough, John William, Waltham Grimsby.
Hyde, John Knowler, Witney, Oxon.
Jenkins, John, Cowbridge.
Loane, Joseph, Dock-street, Whitechapel.
Mallory, Henry Leigh, Knutsford, Cheshire.
Manistry, Francis Steuart, Gresford, Denbighshire.
Napper, Albert Arthur, Cranley, Surrey.
Newsam, Alderson, Totnes, Devon.
Quick, John, Penzance.
Ryley, James Beresford, Myshal, Co. Carlow.
Seatchard, Thomas Edward, Thorp Arch, Tadcaster.
Stothard, James, Hull.
Sykes, John West Ardsley, Yorkshire.
Turner, Arthur Cromack, Swinton, Yorkshire.
Watson, William Charles, Pool, Cornwall.
Wood, Horatio, Wednesbury.

Admitted Members on the 9th inst. :—

Bailey, John Coyte, Plymouth.
Boldero, Frederick, Rattlesden, Suffolk.
Bonney, William Augustus, Brompton.
Cole, Thomas, Bath.
Dale, Frederick, Yarm, Yorkshire.
Davies, Nathaniel Edward, Llanrwst, Denbighshire.
Draper, William, Grantham.
Edmonds, Charles George, Peckham.
Elliston, George Sampson, Ipswich.
Fagge, Herbert William Hythe, Kent.
Hardwicke, Ezra John, Bury St. Edmunds.

Moore, Walter, Myton, Warwickshire.
Palmer, William Grimes, Loughborough.
Paull, Josiah, Camborne, Cornwall.
Quick, Thomas Joseph, Brixton.
Smith, William Henry Firebrace, London.
Strange, Frederick William, Beenham, near Reading.
Walker, Charles Edward, Stainland, Yorkshire.
Wickham, James, Bideford, Devon.

(From the list of gentlemen who passed the Primary Examination at the College on the 11th inst., the name of Mr. Richard Samuel, of St. Bartholomew's Hospital, was omitted.)

APOTHECARIES' HALL.—The following gentlemen passed their Examination in the Science and Practice of Medicine, and received certificates to practice, on the 3rd inst. :—

Allcock, Christopher, Nottingham.
Coalbank, Isaac, Old Dalby, Leicestershire.
Humphrey, Arthur, Balham-hill.
Kisch, Albert, Circus-place.
Parsons, Frederic William, Sutherland-place, Bayswater.
Tattersall, William James, Bacup, Lancashire.

The following gentlemen also on the same day passed their first examination :—

Anderson, J. G., St. Mary's Hospital.
Wood, William Henry, St. Mary's Hospital.

COUNTY AND CITY OF CORK MEDICAL AND SURGICAL ASSOCIATION.—The following gentlemen were elected for the ensuing year :—

President—E. R. Townsend, jun., M.D.
Vice-President—J. W. Johnston, M.D.
Secretary—F. A. Purcell, M.D.
Treasurer—J. G. Curtis, M.D.

Council.

Eugene Finn, A.B., M.B. | D. Cremin, M.B.
N. J. Hobart, M.D. | W. J. Cummins, M.D.
T. S. Shinkwin, M.D. | W. C. Townsend, M.D.

THE LATE MR. W. DUNDASS KEY.—We are glad to recognize the generous spirit which prompts many members of the profession to aid the widow and imbecile son of one among us who died in poverty. A concert will take place at Collard and Collard's Rooms, Grosvenor-street, London, on Friday, May 25th, at which several eminent artists will kindly give their service; and it is hoped that on such an occasion the efforts of the philanthropists who have come forward to help the unfortunate will be rewarded by a full attendance of their friends. Tickets can be procured of Dr. De Lisle Allen, 57, Connaught Terrace, Hyde Park, and at all the principal music shops.

DRUMLISH DISPENSARY.—Dr. Gwydir of Cartron Abbey, was unanimously elected medical officer of the above-named dispensary district, by the committee of management, at the dispensary in Drumlish, presided over by the Right Hon. the Earl of Granard, K.P., as chairman. It is not always we feel it necessary to congratulate public bodies on their appointments, but Dr. Gwydir's unanimous election reflects credit on the noble chairman and the committee, who evinced a praiseworthy zeal for the amelioration of the sick poor, the law confided to their care by appointing a medical officer in whose urbanity and professional skill the public have unlimited confidence.

At the meeting of the Royal Society on Thursday last, the list of selected candidates, recommended by the Council for election into the Society, was read. The names are as follows :—J. C. Bucknill, M.D.; Rev. F. W. Farrar, W. A. Guy, M.B.; J. Hector, M.D.; J. W. Kaye, Hugo Müller, Ph.D.; C. Murchison, M.D.; W. H. Perkin, the Ven. Archdeacon Pratt, Capt. G. H. Richards, R.N.; T. Richardson, W. H. L. Russell, Rev. Dr. Selwyn, Rev. R. Townsend, and H. Watts, B.A. Three of the fifteen are mathematicians, four are of the medical profession, and three are chemists. Dr. Hector is Director of the Geological Survey in New Zealand, and Archdeacon Pratt resides at Calcutta. The election is fixed for the 7th of June.

Appointments.

LONDON.

W. H. DICKINSON, M.D., Assistant-Physician to St. George's Hospital, vice J. W. Ogle, M.D., resigned.
F. J. FARRE, M.D., has been elected Physician to the Charter-house.
The Rev. G. HENSLow, Lecturer on Botany at St. Bartholomew's Hospital Medical School, vice F. Harris, M.D., resigned.
J. W. OGLE, M.D., Physician to St. George's Hospital, vice H. A. Pitman, M.D., resigned.

A. J. POLLOCK, M.D., Physician to the Foundling Hospital, vice J. Spurgin, M.D., deceased.
 W. SMITH, M.R.C.S.E., House-Surgeon to the West London Hospital, Hammersmith.
 Dr. M. TOSGE, M.A., Lecturer on Physiology at the Medical School of Charing-cross, vice Dr. Hyde Salter, F.R.S., resigned.
 J. C. BAILEY, M.R.C.S., Assistant Medical Officer to the Three Counties Asylum, Stotfold, Baldock.
 J. W. COFFESS, M.D., Medical Officer for the Royal Portsmouth, Portsea, and Gosport Hospital.
 Mr. N. DALTON, of Guy's Hospital, Assistant to the House Surgeon of the Northampton General Infirmary.
 M. H. GRATTAN, L.K.Q.C.P.I., Medical Officer to the Workhouse, of the Chipping-Ongar Union, Essex, vice James Shilleto, M.R.C.S.E., resigned.
 W. HADIN, L.Q.C.P.L., Medical Officer of the Royal Portsmouth, Portsea, and Gosport Hospital.
 G. JACKSON, L.R.C.P.L., House-Surgeon to the Bolton Infirmary and Dispensary.
 J. R. KEALY, M.D., Medical Officer for the Gosport District, Royal Portsmouth, Portsea, and Gosport Hospital.
 K. E. KNIGHT, M.R.C.S.E., Medical Officer of the Royal Portsmouth, Portsea, and Gosport Hospital.
 J. W. M'CLOY, M.D., Resident Medical Officer, to the Liverpool Workhouse, Infirmary and Fever Hospital.
 J. A. PALANQUE, L.R.C.S.Ed., Assistant House-Surgeon, to St. Mary's Hospital, Manchester.

Medical Diary of the Week.

LONDON—WEDNESDAY, MAY 16.

ROYAL COLLEGE OF PHYSICIANS.—5 p.m. Dr. Andrew Clark, "On some Points in the Minute Anatomy of the Lung; on the Theory of Pulmonary Hepatization; and on the States of Lung comprehended under the term Phthisis Pulmonalis."
 HUNTERIAN SOCIETY.—8 p.m. An open Meeting.

THURSDAY, MAY 17.

ROYAL INSTITUTION.—3 p.m. Professor Huxley, "On Ethnology."
 HARVEIAN SOCIETY OF LONDON.—8 p.m. Dr. Richardson will exhibit his Instruments for producing Local Anaesthesia.—Debate, "On Infanticide in its Medical and Social Bearing."

FRIDAY, MAY 18.

ROYAL INSTITUTION.—8 p.m. Rev. C. Pritchard, "On the Telescope."

SATURDAY, MAY 19.

ROYAL INSTITUTION.—3 p.m. Professor Huxley, "On Ethnology."
 METROPOLITAN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—7½ p.m.

Births, Deaths, and Marriages.

Announcements are inserted without charge, and must in all cases be authenticated with the signature of the sender.

BIRTHS.—ENGLAND.

GREENWAY.—On the 25th ult., at Sandy, Bedfordshire, the wife of Dr. J. R. Greenway, prematurely, of a son.
 KNAGGS.—On the 29th ult., at Osborne-place, Winchester, the wife of H. Knaggs, M.R.C.S.E., Assist.-Surgeon Army, of a daughter.
 MAJOR.—On the 30th ult., at High-street, Hungerford, Berks, the wife of Harry P. Major, M.D., of a son.
 WOLSTENHOLME.—On the 30th ult., the wife of J. H. Wolstenholme, M.R.C.S.E., of Holywell, Flintshire, of a son.
 DONALD.—On the 30th ult., at Paisley, the wife of J. T. Donald, L.R.C.S.Ed., of a son.
 MURRAY.—On the 4th inst., at Newgate-street, Newcastle, the wife of John C. Murray, M.D., of a daughter.
 PARROTT.—On April 27, at Clapham-common, the wife of J. Parrott, M.R.C.S., of a son.
 SMITH.—On May 8, at Hay, Breconshire, the wife of J. E. Smith, M.R.C.S., of a daughter.

BIRTHS.—SCOTLAND.

ORR.—On May 3, at Idvies House, Forfarshire, the wife of J. H. Orr, M.D., C.B., Deputy Inspector-General of Hospitals, Her Majesty's Indian Army, of a son.
 PATERSON.—On April 24, at Balbeggie, Perthshire, the wife of G. K. Paterson, L.R.C.P.Edin., of a daughter.
 ROBERTSON.—On April 24, at the Towns Hospital, Glasgow, the wife of A. Robertson, M.D., of a son.

BIRTHS.—IRELAND.

MCBRIDGE.—On the 22nd ult., at Newry, the wife of Dr. A. McBride, of a son.
 CORRY.—On the 3rd inst., at Liffey-vale Chapelizod, Co. Dublin, the wife of H. W. Corry, Surgeon, of a daughter.
 GORDON.—On the 4th inst., at Haymount, Bridge of Allan, the wife of Dr. W. E. Gordon, of a son.
 WALLIS.—On April 17, at Mullingar, the wife of W. Wallis, Staff Surgeon 12th Depot Battalion, of a son.

MARRIAGES.

BROOKE—BURNETT.—On May 8, at St. Giles', Camberwell, T. L. Brooke, L.R.C.P.Lond., to Emily Alice, third daughter of J. Burnett, Esq., The Avenue, Gipsy Hill.
 WATSON—BEWLEY.—On the 26th ult., Monkstown, Wm. Tyndale Watson, M.R.C.S.E., of West-green, Tottenham, to Isabella, daughter of W. Bewley, Esq.
 WILLIAMS—PERCEVAL.—On the 30th ult., at Rathspect, Richard Pope Williams, M.B., to Mary, daughter of the late Robert Perceval, Esq.
 MASON—BOWHILL.—On the 3rd inst., at Dunbar, George Mason, M.D., Surgeon R.N., to Elizabeth Walker Bowhill, daughter of James Bowhill, Esq.

DEATHS.

WOOTTON, W., M.R.C.S.E., of Harrold, Bedfordshire, on the 9th ult., aged 66.
 PIX, THOS., M.D., of Castledermot, Co. Kildare, on the 4th ult., aged 60.
 COLLIER, JAMES S. C., L.R.C.P.Ed., at Cairn Cottage, near Edinburgh, on the 15th ult.
 ALLANSON, JOHN, M.R.C.S.E., of Upper Nascott, Watford, Herts, formerly House-Surgeon to the Leeds Infirmary, on the 4th inst.
 BALLY.—M. Bally, the "father" of the Académie de Médecine, has just died, at the age of 92, in the full possession of all his faculties.
 LARMUTH, M. O., M.R.C.S.E., of Salford, on April 21, aged 42.
 MICHON.—M. Michon, Member of the Academy of Medicine and Professeur Agrégé of the Faculty of Medicine, died last week, aged 63.
 SHAW, W., M.R.C.S.E., of Hampstead, on April 27, aged 57.
 CAPPER.—May 5th, died at Hastings, Edith, daughter of Jasper Capper, M.D., aged seven months.
 CAPPER.—May 10th, died at Hastings, aged 29, Jasper Capper, M.D., late of Ipswich.

IRISH MEDICAL ASSOCIATION, ROYAL COLLEGE OF SURGEONS IN IRELAND.

Notice is hereby given, that the Annual

Meeting and Dinner of the Irish Medical Association will take place on Monday, the 4th June next.

The Meeting will be held at the Royal College of Surgeons, Dr. MACKENZIE, President of the Association, will take the Chair at Twelve o'Clock.

The DINNER will take place at the Exhibition Buildings, Earlsfort-terrace, at Seven o'Clock.

By Order,

E. J. QUINAN, M.D., Hon. Sec.

Vacancies.

LONDON.

Westminster Hospital.—Resident House-Surgeon; no salary; free board and lodging.

Carey-street Dispensary.—Resident Medical Officer; salary £100, with residence.

South London Dispensary.—Lambeth District, surgeon.

PROVINCIAL.

Scarborough Dispensary.—House-Surgeon and Secretary; salary £100, with apartments, fuel, light, and attendance.

Stockport Infirmary.—Assistant-House-Surgeon; salary £60, with board and apartments.

Bridgworth Infirmary.—House-Surgeon and Apothecary; salary £70, with fuel and light.

POOR-LAW MEDICAL VACANCIES.

Banbury Union.—Hornton District; area 7740; population 3062; salary £61 8s. per annum.

Godstone Union.—Eastern District; area 9302; population 2308 salary £73 per annum.

Baith Union.—Abergweessin District; salary £50; area 68,480 population 3784.

Notices to Correspondents.

The Royal Institution of Great Britain.—The notices have been received.

Aliguis.—The mineral waters in question contain a considerable quantity of soda in combination with a large amount of carbonic acid.

Mr. T.—We cannot find the name in the Medical Register, or in the London and Provincial Medical Directory.

M.R.C.S.—The pay is the same as in the Royal West India Steam Packet Company—namely, above £120 per annum. The appointment rests with the Directors.

A Medical Reformer.—It is too late now to rake up the particulars of the numerous defunct Medical Bills which were brought before Parliament. The present Medical Act, although the last, is by no means the best of the series.

Mr. Harry Leach.—The paper has been received.

A Parent.—There are now two examinations for the Matriculation of the University of London—namely, in January and June.

Mr. B. T.—We have heard the names of two candidates for the vacant appointment.

A Country Practitioner.—The specimens may be seen in the Museum of the College.

Dr. J.—The paper has been received.

The Pharmaceutical Society of Great Britain.—The card has been received.

WEEKLY METEOROLOGICAL REPORT FOR THE WEEK ENDING MAY 12TH, 1866.

LECTURE ON MERCURIAL TRADE DISEASE.

By E. D. MAPOTHER, M.D.,

PROFESSOR OF HYGIENE, ROYAL COLLEGE OF SURGEONS, ETC.

GENTLEMEN,—As you have had an opportunity of seeing two cases of slow mercurial poisoning, and as the disease is due in a great measure to the neglect of precautions which should be made obligatory on manufacturers by the authorities to whom the care of the public health is entrusted, I have chosen these cases as the subject of my observations to you this morning.

The first, that of P. K., has been under Dr. Quinlan's care for some weeks, and he has kindly allowed me to refer to it. This man, who is aged 50, has worked for twenty years at the mirror silvering trade without intermission, except when disabled by the effects of the mercury. His habits have been temperate, porter being the only stimulant he took. He has been very neglectful of ablution before meals, and of ventilation in the room in which he worked. The first symptoms he suffered from were, coppery taste, salivation, weakness, depression, and irritability of spirits; but for about four years he did not suffer from the tremor. At this time the constant habit of his bowels was to move six times a day, and they were frequently over-distended with gas. He was very apt to sweat on making the least exertion, the perspiration having the peculiar mercurial fœtor. When admitted into hospital he was wretchedly emaciated, every muscle trembled, and he stutted constantly. He had a very distinct purple spongy line along the teeth. His skin has a peculiar bluish paleness. He did not tremble during sleep, but was very uneasy and apt to start up.

The treatment which Dr. Quinlan most successfully employed consisted in iodide of potassium and generous diet, galvanism, and warm baths. The peculiar kind of stammering from which this poor fellow suffered has been called "psellismus mercurialis." This symptom was retained for thirty years in the case of Dixon, the anatomy porter of the College of Surgeons, who at one time rubbed in immense quantities of mercury for the cure of venereal among the "mohawks" or swells of that day. Professor Macnamara tells me that his chief difficulty lay in the pronouncing of long words, such, for instance, as that gentleman's polysyllabic name.

The second is that of J. T., who, although only 28 years of age, has been working at the silvering trade for sixteen years in this city and in Liverpool. Having been lately a patient for erysipelas in the Richmond Hospital under Dr. Fleming's care, that gentleman, knowing I was interested in the matter, kindly sent him afterwards to me. The first thing he observed on beginning the trade was a nasty taste in the mouth, not the usual taste of mercury distributed through the system, for it began in three or four hours after the first exposure. Salivation followed, and was renewed whenever he went back to work after an interval. So extreme had been the action on the mouth that he had lost nearly all his teeth, and, as in P. K.'s case, there was permanently a red spongy edge to his gums. He had at one time been as helpless as a child, and had suffered from incontinence of urine and fœces. He is now very bald, and this, with the characteristic paleness and wrinkled state of his face, gives him the appearance of a very old man. Loss of spirits, weakening of virile power, and disinclination for the least exertion

or for amusement, were the early symptoms, and he at last became as apathetic as a sailor with sea scurvy, and, by the way, from the same cause, want of red blood-cells. He lost appetite for food, but drank porter rather plentifully. Spirits he could not touch, as a very small quantity would intoxicate him in his weakly state. He always had more or less of the "trembles," and even now, after several months' abstinence from work, shakes a little, and as the muscles have no enduring power of contraction, he cannot stand steadily. I may mention that he never knew a fellow-workman escape the disease in Dublin, whereas in Liverpool a minority suffered.

You see, therefore, that the ill-effects of this trade are very deplorable, and, if generally known, would cast an expression of sadness over many a face reflected in the mirrors, the making of which have caused the evils; but, happily, they are in a great measure preventible.

The nature of the disease is somewhat obscure, but must consist in one or more of the following conditions: the spoiling of the nervous tissue, of the muscular tissue, or of the blood, of which you know a pure and plentiful supply is wanted for active muscular movement. Into all of these components of our body albumen, and the substances allied to it enter most largely, and it may be that the mercurial salt coagulates and spoils them in the body, as it would in the chemists' test tube. A grain of corrosive sublimate will coagulate some hundreds of grains of albumen before its effects are neutralised. So that when Baron Thénard had accidentally taken a little of that poison he had to swallow as an antidote about a dozen eggs. The blood cells are composed of an albuminoid, and when they have disappeared by prolonged maceration in water, a drop of a solution of bichloride of mercury will coagulate this compound and make them reappear.

1. That it is not on the nervous tissue the mercury inflicts the greatest injury I think appears from the facts that its other functions—memory and sensation, for instance—are not impaired, and that in most cases cure follows avoidance of the poison and perhaps medical treatment within a few weeks. In two cases lately published in the "Bartholomew Hospital Reports," the symptoms, however, produced were those of acute mania, and in one the post-mortem appearances of the brain corresponded with this condition. The poison was introduced by the vapours of mercuric methide. The brain is no doubt highly albuminous, but that substance is contained in the interior of the nerve tubes, and is insulated by a coating of fat. Its remarkably low diffusive power also would tend to keep it within the tubes.

2. If an opportunity of examining the body of a silversmith should arise, it will be possible to ascertain if the mercury has penetrated the sheaths of the ultimate muscular fibres and shrivelled the albuminoid within them, and that perhaps it still lurks there itself. I think, however, it is now generally believed that the exerting power of the body is capable of throwing out mineral poisons within a very few days, except perhaps from the lungs, liver, and kidneys, from which they may fail to get discharged. It is not recorded that in cases of mercurial poisoning the metal was found in the muscles.

There is one diseased condition of muscular fibre of which we know the intimate nature—namely, fatty degeneration, in which the musculin is found to be replaced within the sheaths by that fat known as adipocire. This change is accomplished by the evolution of nitrogen, for as no pores can be discovered in the sheath, it is hard to conceive how the musculin could be conveyed out and the fat conveyed in. The fatty muscle has not, however, the irregular mode of contraction which appears in mercurial tremor, but has that sluggish action we see in the muscles of a diseased limb, or of an over-fattened ox, or that proneness to stop altogether which we find in cases of death from fatty heart. However, it is probable that chemical degeneration of the muscle would lead to the trembling which follows mercurial poisoning, and that, whether the muscle be merely an instrument played on

by the nerves or contracts by a force inherent in it, which question you know physiologists still dispute.

I am not aware if the intimate nature of the shaking palsy of old age has been demonstrated, but it is very similar to mercurial tremor, only differing in the fact that the muscles remain quiet if no effort be made to move them. It might be due to either of the foregoing conditions, or that now to be discussed.

3. From the time of Huxham, it is known that mercury spoils the red cells of the blood, and Dr. Farre says, "A full plethoric woman of a purple red complexion consulted me for hæmorrhage from the stomach depending on engorgement without organic disease. I gave her mercury, and in six weeks blanched her as white as a lily." We remark much the same every day in our wards, and the green evacuations of children after a dose of calomel are chemically identical with the colouring matter of the blood. The red cells are by no means permanent, but, on the contrary, are constantly being destroyed by the liver and cast off in the bile, the stock being renewed out of the white cells. This action of the liver is stimulated by mercury, and it is thus a course of that medicine pales the body, as that agent has spoiled many cells. Now, all the silverers I have met with have suffered, especially in the beginning while they had blood to lose, from bilious purging. It is this loss of red cells to even one-sixth of their amount, and necessarily higher proportion of white, which renders the blood of persons under mercury buff and cupped when drawn, and a peculiar fætid matter similar to that which is thrown off in the saliva and evacuations is found in that fluid.

You have probably heard of mercurial erythism, but from the moderate and careful way the drug is now given I nor you have ever seen it. Sir T. Moriarty, however, records that it was very common in Dublin in the beginning of this century. It consisted in sudden and sometimes fatal faintings, presumably due, as I suggested in my "Manual of Physiology" (2nd edition), to rapid destruction of the red cells and consequent failure of the heart's contraction. One of the most graphic accounts of the disease was related by Dr. Bateman, F.R.S., in the ninth vol. of the *Med. Chir. Trans.*, as occurring in his own person, and the prominent symptoms were weakness of the muscular tissue, including that around the intestines, which allowed the accumulation of gas to a most painful extent.

The secretions almost alone increased by mercury, when the action of the bowels is checked by the combination of opium in the saliva, and this may have some connexion with the fact that it contains an albuminoid plentifully, and further it may be that the power of mercury of destroying the venereal poison and removing recently found out lymph, may be by its coagulating power just as it acts on the albuminoids out of the body. It acts in high inflammation by spoiling the excess of blood cells. No tissue requires a more constant, abundant, and pure supply of blood than muscle when contracting; it is therefore easy to conceive that the stream spoiled by the mercury will lead to weak and irregular action. It may be said that the brain would equally suffer, but Chossat's experiments on the starvation of animals proved that while muscles failed and wasted first from the deficient supply of blood so produced, the brain held out almost to the last. In cases of acute mercurial poisoning the tremor appears within two or three days, and there is scarcely time enough, or poison enough, to produce much effect on the brain or muscles, but the increased action of the liver would rapidly impoverish the blood. Mercury has been, moreover, found in the blood, but so intimately combined with albumen that destructive distillation was necessary to extract it, and a decomposed form of albumen was found also in the blood.

Lead, you know, produces a palsy of the extensor muscles of the forearm (why these muscles alone is unexplained), and this is probably due to the direct action of the lead on their tissue, or on the posterior interosseous nerve which supplies them. I must acknowledge that it

weakens my theory of the mercurial palsy, for it cannot be on the blood the lead has acted, else the forearm alone could not suffer. In a case of wasting palsy, in which a few muscles only were affected, Mr. Lockhart Clarke showed that the lesion in the spinal cord corresponded with the origin in that centre of the nerves which supplied them.

Treatment.—So much depends on a knowledge of the intimate nature of the affection that you will not be surprised to hear that there is much uncertainty about it. Believing that the disease consists in a want of good red blood, which the poison has spoiled, I would advise the most nutritious food, fresh air, and iron to improve it. Such treatment is in a few weeks capable of tripling the red cells. Pereira regards medicines as of no use, but others look on iodide of potassium as a specific, and believe that it acts by making a soluble compound with the mercury which escapes in the urine. This view is improbable, for the conversion into a soluble form of the poison should aggravate its effects as it circulated through the system, and the iodide of lead which would be produced in a similar manner in lead poisoning treated with iodide of potassium, is insoluble. The medicine may act by eliminating the albuminoid which has been spoiled by the mercury. Dr. Parkes, Professor of Hygiene at Netley Hospital, has found that the elimination by the kidney of both lead and mercury is increased by iodide of potassium. When mercury passes off in the urine there is always found at the same time in that secretion a peculiar albuminoid, probably combined with the metal. The skin is probably another great eliminating organ for metallic poisons, and baths are therefore most useful.

A bath containing sulphuret of potassium is very serviceable in lead poisoning, and it becomes blackened by the sulphuret of lead after the patient has been a few minutes in it. The same remedy might be useful in mercurial poisoning, or perhaps the salt might be given internally; for Orfila assures us the sulphuret of mercury is innocuous. A dose of sulphur will often stop salivation, as I learned some years ago from a general practitioner with whom I was treating a case in which the action of mercury had been excessive; it may act by forming a sulphuret of the metal.

Galvanism may be useful in the same way as it is with paralyzed muscles—namely, to supply an artificial stimulus and to prevent their wasting, but it cannot remove the cause of the disease. Faradization is the most reliable form.

A gentleman stated to me lately that he read in some magazine years ago that persons intended as miners in mercury mines were rendered insusceptible of the effects of the metal by taking for two or three months previously large doses of arsenic. I have been able to obtain no confirmation of the statement, nor can I understand it; but, if true, it would suggest that arsenic would also be a curative agent.

I may mention that, notwithstanding the drenching of their systems with mercury, silverers are susceptible of the venereal poison in its worse forms, and even may require the internal administration of that medicine to cure them.

The process of silvering, as I saw it conducted, is to place a sheet of tin-foil on a large stone slab, and to pour over it mercury to about a quarter of an inch thick. The glass is then carefully slid over the surface of this amalgam, the oxide being removed to the sides of the stone or the grooves along them, and a lustrous surface being left next the glass. With small and inferior plates they sometimes place a sheet of paper between the mercury and the glass and then withdraw it. It is the oxide or dust, which, being diffused in the air, or introduced from the clothes or skin of the workmen, which produces the disease. On damp days, when mercury rapidly oxidizes, it is difficult to silver, and the men are induced to shut out the air and to raise the temperature by large fires. By such means the danger is greatly increased, as the mercury is vapourized, breathing is quicker, and the perspiring surface catches the mercury.

If the mercury be impure or mixed with dust, or the

slab dirty, it will "tail" on the stone, oxidize freely, and so do more harm.

Workmen are affected with the mercury with remarkably different degrees of severity, which you will not be surprised to hear, if you remember the case related by Mr. Chevalier, in which two grains of calomel prescribed as a purgative proved fatal by salivation and necrosis of the jaw.

Any workmen showing susceptibility should be removed to some other branch of the business, or obliged to relinquish it altogether. That it is very hard to persuade them to such changes may be learned from a case related by Merat, in which both parents had been affected with trembles at his birth and until their death, yet he pursued the business in the most neglectful way.

Prevention I speak of last, because, being "better than cure," I wish to impress it on your memory. It can be accomplished, to a very great degree, by the following means:—1. Free ventilation to be attained by height of premises, open windows, and louvred shafts at the summit of the rooms, or best of all, a special fan and shaft; the mercurial particles will be in these ways carried off. 2. The wearing while at work only of some easily washed dress. 3. Abundant opportunities for ablation of the hands and mouth after leaving work, and always before meals, which should not be eaten in the work-rooms. Frequent baths are also most useful. 4. The wearing of a wire gauze covering over the mouth, nose, and ears; a handkerchief is now occasionally used over the mouth, in the way which even Pliny described, but gives very slight protection. I may mention that of these and similar precautionary measures the men are very neglectful, as is the case also with steel-workers, who can be rarely induced to wear the magnetized gauze, which is most effectual in excluding the particles of that metal. From this astonishing neglect, the average of life of Sheffield grinders is reduced by one-half. 5. Means of catching the dust, such as sheets of strong paper with holes in them placed in advance of the walls. The dust passes through the holes and may be collected in troughs along the edge of the floor. Round the edge of the silvering stone there is a groove for collecting the dust, and it strikes me that if glycerine or some other sticky matter were placed in it or at the edge of the stone, the dust could not rise. Water would not suit for this purpose, as the vapour from it would dull the silvered surface, but the dust might be perhaps swept frequently from the groove into a vessel of water on the floor. The dust is preserved for the purpose of being distilled, and at all times should be kept in air-tight vessels, for mercury volatilises even at ordinary temperatures. 6. Working only at intervals, such as every second day, with an occasional month's respite altogether; this is the habit in England, but no intermission is usual in Dublin. From such neglect it follows that no one going to the business in this city ever escapes the disease, whereas Dr. Whitley, who reported on the subject for the Privy Council, in describing a London establishment says:—"No well-marked case had occurred for many years among men who had worked there only, and he believed that in well-arranged workshops, with cleanliness and temperance, the danger, except to those peculiarly sensitive, is not great. All that I observed in most of the other places I visited served to confirm the above."

At present the legislature does not empower any one to interfere with this and many other injurious employments in this country, but the Public Health (Ireland) Act, which has been drawn up by the Government, I rejoice to say, provides for their due regulation; and an extension of the Factory Acts might arrange the due number of hours of work. At present not more than eight or nine persons are engaged at silvering in Dublin, but the business is increasing. For the entire prevention of the ill effects of mercurial trades, we must appeal to the noble science of chemistry, of all branches of knowledge the most useful to man, and it may be possible by some such method as precipitating the mercury to avoid the danger altogether. Gilding with an amalgam of

mercury and gold was most noxious, but has now been superseded by electro-plating. Some other trades which use mercury, as barometer makers and furriers, also suffer from its effects, as do likewise to a fearful degree the miners who work at Almuden and Idria, near Trieste, where the metal is obtained. In 1803 a fire broke out in the latter mine, and over 900 persons in the neighbourhood were attacked with the trembles. At these mines even at present the mode of extraction is so rude that the miners suffer from the fumes most lamentably. Mercury being volatile, it may occasion disease if it be not carefully stored; thus in 1810, the *Triumph*, man-of-war, having taken a large quantity of the metal from a wreck, the bags burst, and 200 of the men were salivated, and every animal, including birds, mice, and even cockroaches, were destroyed. It was at one time asserted that the corrosive sublimate in the timber, preserved by Kyan's process, was injurious to sailors, but a commission of the French Academy in 1836 disproved the statement.

Before we separate I wish to draw your attention to the case of consumption in the same ward, for this man also owes his disease to an ill-regulated trade. He has been working for about twenty years in a flour-mill near this city, and partly from cupidity and partly from obedience to his employer, for refusal would lead to dismissal, he has often worked both day and night, two hours in the evening alone being given to sleep. He continued to work in this way for six days and nights on one late occasion, but being seized with spitting of blood, he was admitted into hospital. Exhaustion from length of labour, and the entrance of flour particles into his lungs, for these places are often ill-ventilated, excited his disease, and there are very few of the men who work at the trade who do not suffer from difficulty of breathing from the latter cause. In steam-mills night work is not usually allowed, but in water-mills, as the power is so limited, day, night, and Sabbath are alike. Is not such a system to be deplored, and is not legislative interference called for?

THE RECENT OUTBREAK OF CHOLERA IN THE EAST.

By HARRY LEACH, M.R.C.S.E.,

RESIDENT MEDICAL OFFICER HOSPITAL SHIP "DREADNOUGHT," AND LATE MEDICAL INSPECTOR TO THE KASTENDJIE AND OTHER TURKISH RAILWAYS.

In reviewing the rise, progress, and decline of cholera last year in parts of Eastern Europe, many useful points of information can be gleaned, and as we may fairly suppose that the epidemic of last year is a type of that which is likely to come to us during the next few months, we may the more usefully take into consideration experiences that can be gathered from the past. Kustendjie, now one of the chief ports for the export of grain on the western shores of the Black Sea, was, during the autumn of last year, very severely visited with cholera. At this time a small colony of English (about eighty in all) is established there in connexion with the works of the Kustendjie railway and harbour. The houses of the *employés* are most healthily situated on a cliff immediately above the harbour, quite distinct from the native town, and with good natural drainage. The general arrangements of these houses are airy, and, under ordinary conditions, the sanitary state of the colony is very satisfactory. But cholera commenced there on the 4th of August, 1865, continued for about three weeks, and was fatal to no less than 17 per cent. of the inhabitants. Dr. Cullen, resident medical officer to the company, states that in every case a history of preventible diarrhoea was distinctly made out; that in many instances this was cured by an ordinary astringent mixture, but that relapses took place in consequence of gross carelessness on the part of the patients, when in a state of convalescence. Pork was eaten by some, melons and grapes by others, and in all these cases, as a natural

consequence, the relapse was speedy, and generally fatal. It appears to have commenced here, as elsewhere in Turkey, very insidiously, and to have stopped suddenly when at the height of its intensity, ending, as the Italians would say, *fulminante*.

I tried in vain to fix a cause for this severe visitation to the English colony at Kustendjie. for the *locale* is so exceptionally healthy that no place seemed to be formed so happily, both as to situation and general arrangements, for exemption from any epidemic. Ague is constantly rife here, and there is certainly a want of good water close to the houses. But the inhabitants of Scarborough Spa Cliff, or those of the mills about Hastings, are not more breezily located than are this little company of English on the coast of the Black Sea. The presence and prevalence of cholera at Odessa, Ibraila, Sulna, and Galatz, is by no means surprising, as these towns all, more or less, partake of the superlatively dirty character common to places in these districts. It is a fact worthy of notice, that in no instance does the epidemic of last year appear to have penetrated inland, as far as concerns Turkey, and, with one notable exception, all places on the shores of Bulgaria were attacked. Varna is this exception, and it is certainly a very strange fact that this particularly unclean town should have so completely escaped. Varna is well known to many Englishmen of Crimean experiences, and in war time dirt therein was of course inevitable. But having seen most of the towns in Bulgaria, and resided at Varna for some weeks in the cleanest months of the year, I must certainly agree with all travellers who know it well, in saying that it would give an unequalled field, among the many Augean stables in that country, for an active inspector of nuisances. Of drainage there is literally none. The lower parts of the town are in a constantly spongy state from the fluid refuse of the upper district, and you must wade through a sea of tenacious mud to reach the custom-house or harbour gate. A large tract of low marshy ground stretches along its southern wall, and it is said that the roads around are in winter well nigh impassable; but no case of cholera occurred here last year, and we may cite it as one among the many vagaries recorded of this and former epidemics. Passing through Bulgaria, and reaching the right bank of the Danube, we come to Rutchuck, a town containing about 77,000 inhabitants, of mixed population. This place is, comparatively speaking, tolerably clean. The cholera appears to have been brought here from Kustendjie, by a party of workmen who had fled thence in consequence of its ravages in and about the latter town; it commenced on the 12th of August, and lasted three weeks, killing at the rate of ten or eleven per day. Mr. Hayes, Resident Medical Officer to the Railway Company here, worked very hard indeed among the native population, but found great difficulty in applying any sort of remedy. He authenticates four recoveries from the stage of collapse, and in these cases the treatment consisted in friction, mustard poultices, and general astringents. The necessary apparatus for hypodermal injection was sent out to him by the Company's Secretary, but did not arrive until the cessation of the epidemic. It is clear that here, as at Kustendjie, the disease commenced with simple diarrhoea, that very few, if any, cases of sudden collapse occurred, and these at the end of the epidemic. Its *finale* here, too, was sudden and complete, but the panic severely affected the progress of the railway works, though the mortality among the English *employés* was very small, only two cases of cholera and one death having occurred. On the coast line from Varna to Constantinople, the only town, properly so-called, is Burgas, which possesses a good natural harbour, and is in fact the port of Adrianople. The one medical man resident here told me that no cholera had appeared, but that many fatal cases of ague had recently occurred among the inhabitants of the town and district. Mortality from ague is, I think, somewhat incomprehensible, and such is the difficulty of arriving at positive truth in Turkey, that I am fain to cast a doubt on the stated causes of death in

this locality. The town rivals Varna as to dirt, and it is astonishing that any sort of commerce can be carried on with the excessively meagre accommodation for goods and traffic.

Pass we now to Constantinople, which, during last year, as in years gone by, was the great focus from which radiated all other branches of the Eastern epidemic. All medical authorities of the Porte agree that the disease was brought from Alexandria by the Imperial steamship *Moukhir Sourrou*—that a false clean bill of health was given by the officers in charge of this vessel, and that its inmates were therefore allowed to land immediately, with cholera actually present among them. As soon as the evil was discovered an order of isolation went forth, but as this came late, and even when practised was far from complete, the disease speedily spread far and wide. A carpenter working at the isolated barrack in which the infected troops were placed, went home, and took the disease to his village (Yenikuei) up the Bosphorus. A family living immediately over an open sewer in which flowed the drainage from this barrack, migrated to Tatalva, another district of Constantinople, and there propagated the disease. In each district of this vast city the malady was traced to a distinct focus, and the testimony of all medical men is unanimous on this head. It was observed by Dr. Dickson, physician to the British Embassy, that in a former epidemic the disease was fatal, to a slight extent only among the Mussulmans during the Ramadan. While this feast or fast lasts, the Mahomedans go from home very little (their women not at all), and eat in the night. When, however, the feast ended, and the women went to the bazaars to buy necessary articles for the Biram, the disease commenced and spread rapidly among them. It is universally remarked that this last epidemic was decidedly milder than those of 1848 and 1852; that some cases of sudden collapse occurred towards its close—i.e., when its height was reached—but that in the vast majority of cases controllable diarrhoea existed at the commencement of the attack, and, if at once attended to, was cured by ordinary astringent remedies. The fact, however, that melons and other vegetables form the staple diet of the poorer population of the Ottoman empire is of itself a great obstacle to the successful treatment of incipient cholera, exclusive of the fearful amount of disregard to all sanitary precautions of the most obvious description. The population of Constantinople is estimated at 1,000,000, and it is computed that 20,000 deaths occurred in that city during the last epidemic of cholera. I received, in pursuing my inquiries, much kind courtesy from all medical residents at Pera and elsewhere. After carefully gleaning a history of remedies used by all, and eliminating such as are familiar to every practitioner, as having been tried with very variable and doubtful success, I found that a majority of opinions were in favour of quinine rubbings and quinine injections (hypodermal); remedies which are, I believe, almost if not entirely novel in this country. The patient is rubbed for some time in the ordinary manner, the hands of the operator and skin of the patient being well sprinkled with a saturated solution of quinine. This was said to have been very successful in cases occurring in children.

The agenda, as to hypodermal injections, are now familiar to most practitioners in England, and it is recommended that a tolerably strong solution of quinine be thus injected at various parts of the body.

I am by no means prepared to explain the *rationale* of this treatment, nor was any explanation afforded me; but our list of remedies is at present so meagre, that this can claim at all events a trial.

A recapitulation of facts connected with the epidemic of last year in Eastern Europe may reasonably lead us to several hopeful conclusions. It was undoubtedly a milder scourge than that of previous years. It was as undoubtedly of a more preventible character. Having reached a certain degree of intensity (by no means comparable with that of former epidemics), it ceased absolutely and entirely.

As to means of prevention and cure, we have gained this much, and should actively use that knowledge.

As to the former, considerable good may be done by a more complete system of isolation than has as yet been practised in this country, for we cannot now close our eyes to the fact that the disease is, to a certain extent, contagious. Of the latter, it is emphatically our duty to warn all persons, young and old, as to the dangerous results of neglected diarrhoea.

Too much cannot be said or done on this head, and it is hard to say how many cases may not be saved among the poorer classes in this metropolis, by spreading a warning far and wide, and providing at the same time ready and gratuitous means of relief in every district, and in every street of that district, where a chemist's shop exists.

We must use most strenuously our powers of prevention, for, it must be owned with humiliation, that they are far greater than our powers of cure.

TREATMENT OF ASIATIC CHOLERA.

By R. M. FORSAYETH, M.D.

At a time when a visitation of Asiatic cholera is not unlikely from its proximity in neighbouring countries, unless otherwise ordained by Providence, I feel called upon to offer a few practical remarks upon alcoholic medication in its treatment, and also such statistics as have come within our reach upon that subject, preventive or curative. A prevalent idea occupies the public mind, that some preventive measure, as alteration or change of diet, or medicine is necessary at such a time. This seems true only in one or two particulars:—

1st. If the mode of life or diet is acting detrimentally on the health a change may prove beneficial.

2nd. An early abandonment of habits of intemperance.

Any other precautionary changes impressing the mind with the likelihood of an attack act injuriously.

A Russian physician states, "It is a positive fact that cholera does not seize on its victims at hazard, as many say. It has been ascertained that out of every hundred individuals who die of this disease, ninety are in the habit of drinking ardent spirits to excess."

Mons. Huber, who saw 2160 perish in twenty-one days of cholera in one town in Russia, says, "It is a most remarkable circumstance that persons given to drinking have been swept away like flies. In Tiflis, containing 20,000 inhabitants, every drunkard has fallen—all are dead, not one remains."

Dr. Rhineland, visiting Montreal in 1832, states, "The victims of cholera are the intemperate." A Montreal journal states, "That not a drunkard who had been attacked had recovered, and almost all the victims have been, at least, moderate drinkers."

Dr. Bronsen of Albany, states, "Drunkards and tipplers have been searched out by cholera with such unerring certainty, as to show that the arrows of death have not been dealt out with indiscrimination; there seems to be a natural affinity between cholera and ardent spirits, and their habitual use in the smallest quantity seldom fails to invite the disease and render it incurable when it takes place."

Professor Sewall, M.D., visiting New York, says, "That of 204 cases in the Park Hospital there were only six temperate persons, and that these had recovered."

Dr. Mussey, U.S., says, "Upon boats on the river the increase of brandy drinking, consequent on the approach of cholera, has been frightful, and the mortality on board these vessels has been terrible and unprecedented. When this dreadful scourge was raging in New Orleans, amongst the hundreds that were swept off by the disease, only two were sons of temperance, and among the 1200 of that city only three were attacked."

The great and good Mr. E. C. Delevan writes, "In 1832 when the cholera broke out in Albany I was engaged with E. Corning and J. T. Norton in erecting that large block of buildings on Green, Beaver, and Norton-streets. About

100 men were employed, they were all about abandoning their labour, when they were persuaded to remain. They all agreed to keep at their work and abstain from strong drink. A beverage of water molasses and ginger was furnished them free, and of all those 100 men engaged on the work not one died, nor was the work intermitted a day; one man not under the control of the builders (those excellent mechanics, Fish and Mawley), but employed by the man who furnished the brick, would not adopt the simple beverage offered to him but resorted to the grog shops. He fell a victim."

Professor Miller says, "Of 70 male adults affected with cholera in Edinburgh Hospital in 1848, only 17, according to their own account, had led tolerably temperate lives, and of 140 females attacked by the disease only 43 were reported sober."

Professor Mackintosh of Edinburgh, who was physician to an extensive cholera hospital, states, "It has been computed that 5-6ths of all who have fallen by the disease in England were taken from the ranks of the intemperate and dissolute."

Dr. Adams of Dublin, affirms, "Our foreign reports testify that drunkards are carried off at once by this dire disease; but those who by a daily use of a moderate quantity debilitate the tone of the stomach and biliary organs become easy victims to the cholera."

The Rev. Wm. Reid of Edinburgh, in his "Temperance Cyclopædia," says, "Dr. A. M. Adams, Professor of Medicine in the Andersonian University of Glasgow, has favoured us with a classified statement of the previous habits and conditions of health of 225 cholera patients treated by him during the epidemic of 1848-9. From this table it appears that whilst those patients, who were represented to him as being of temperate habits, died only in the proportion of 19.2 per cent., those who were of intemperate habits died in the enormous proportion of 91.2 per cent."

I might multiply statements such as these, but assuredly they ought to be quite sufficient to establish the principle of the imperative necessity of refraining from the use of alcohol, either as a prophylactic against an attack of cholera, or a remedial agent for its cure. This latter I had an opportunity of testing during the dreadful invasion of 1832 as well as 1848, when I relinquished brandy for pure cold water with marked benefit. In corroboration of this statement, I could quote those of some other medical men, but refer just now to only one detailed in THE PRESS of 27th December, 1865, in an article on cholera, translated from the French by Dr. T. M. Madden:—

"The action of cold water in cases of cholera was, however, I believe, first pointed out thirty-two years ago by an Irish medical practitioner, Dr. McCoy, in the *Dublin Quarterly Journal of Medical Science*, and as the article in question is probably unknown to many readers of the PRESS, I shall quote the passage to which I refer:—

"Among the strongest prejudices," says Dr. McCoy, "I brought into the hospital was that against cold water. One of the India reporters, I recollect, states that he never knew a patient recover who was allowed cold water to drink, and other writers denounced it, though not so emphatically. I accordingly requested the nurses not on any account to comply with the entreaties of the patients for cold water. On the 2nd May, a female named Margaret Tusky, aged 21, was admitted into one of my wards at four o'clock in the evening; she had been nine hours ill; the surface of her body quite cold; her feet, legs, hands, eyelids, and nose were blue; no pulse could be felt at her wrist; vomiting incessant of the rice-water kind; she had two or three alvine dejections before admission; eyelids half closed, and eyes turned upwards; thirst very great; calls for cold water urgent; cramps very distressing; tongue cold and white; pain just below the sternum, which she attributed to having drunk two pennyworth of buttermilk during the morning. The necessary measures were resorted to for her. This girl, having observed that a pail of cold water had been left near her bed for some

ward purposes, contrived during the evening to draw herself towards it, and putting her head into the vessel drank copiously; it was speedily thrown up again, but the draught was repeated as often as she could without being detected. When I heard of it, I was of course alarmed for the consequences. However, during the night, a patient in the same ward in a convalescent state, who had felt the deprivation of water herself, not long before, got out of bed several times and supplied Tusky with cold water. This she told me herself the following morning after I had expressed my satisfaction at finding her so much better than when I left her the night before. She recovered. This incident demonstrated that the indulgence in drinking cold water was, at least, not certainly fatal. I therefore commenced giving it in small quantities when called for, and soon after allowed them to drink as much of it as they pleased. I found it the best drink of any I had yet tried, and by far the most agreeable."

I could multiply cases exactly similar, one in particular detailed to me near Cork, confirmatory of the foregoing remarks, "Cold Water versus Brandy Cure;" but having already taken up so much of your valuable space, I think it not necessary, sincerely hoping by those few details to draw the attention of our noble and philanthropic profession to the disastrous evils resulting from the indiscriminate alcoholic medication of the present day.

Templemore, May 13, 1866.

NOTES OF SOME CASES OF ECZEMA.

By JOHN S. A. CUNNINGHAM, L.K.Q.C.P.I., L.R.C.S.I., &c.

Few departments of medicine present more diversity of detail both in the description of, and treatment applicable to them, than do that class of affections comprised in the general term skin diseases; indeed, most persons comparing the various descriptions of different authors would, on a first perusal, be at a loss to recognize the disease described were it not for the title prefixed, so great is the difference observed in the various descriptions contained in books on general medicine. I do not now allude to works exclusively devoted to this class of diseases, in most of which true and correct details are given of the various phases under which these affections are observed in practice, as far as verbal descriptions can portray; but, in truth, even here we experience a loss, for these diseases are of that nature which require to be *oculis subjecta fidelibus*, still by a faithful record of actual cases observed in *corporis vili*, much may be done to render the history even of these affections more complete and accurate than has to the present day been accomplished even in our best treatises; so that a true account of every case should be looked upon as one step nearer that goal so much to be desired—the enrolment of the science and art of medicine amongst the "exact sciences."

Eczeema may be defined to be a vesicular eruption unaccompanied, in general, by much inflammation or febrile disturbance, and terminating in re-absorption of the contained serum, either by desquamation or excoriation. Its exciting causes are various; in the idiopathic forms it generally depends on irritation of some sort, as an example of which, I give the following case extracted from my note-book, as being the worst form of the affection I have ever seen:—

Bridget Lambe, aged 28 years, unmarried, a servant, of nervous temperament, never enjoyed good health, though not so sick as to be incapacitated for work; no hereditary disease in her family; came under my observation September 15, 1860. She states that about three months since, in consequence of tenderness of her eyes, thinking should she get ear-drops it would have a beneficial effect, so had her ears pierced; three days after she noticed a crop of red pimples, somewhat resembling "flea bites," about the angles of each inferior maxilla, these gradually spread upwards to the ears, and inwards, so as to form a circle underneath the chin, these became vesicular, and shortly

after bursting discharged a thin serous fluid, the only application being lukewarm water, which afforded relief. A few days after like pimples made their appearance on the abdomen and lumbar region of the back, attended, however, with heat, redness, and diffused inflammation generally of the parts, vesicles forming as before burst and discharged a thin purulent fluid which, drying, formed crusts on the surface, these gradually extended till a complete zone formed around the lower part of the body. At the same time the pain becoming acute, she applied for medical relief in the neighbourhood, and obtained some ointment (of a white colour, does not know its composition), which was to be rubbed well over the crusts and place of disease, generally every night and morning. This was accordingly done the night after, and the next morning the side of the face, abdomen, and back, and, in fact, every place where the ointment had been applied, was much swollen and very painful, so that she did not rub it again nor try any other remedies; but having contracted catarrh from exposure to a severe wetting, she became feverish with great aggravation of all the existing skin disease. When I saw her the following was her condition:—A complete zone of vesicles surrounds the face, some of which have burst and discharged their contents, forming crusts extending over both ears, and for two inches posterior to the concha, which is one mass of desquamation of a dark straw colour mingled with patches of red; glands of the neck are enlarged and painful; the abdominal, axillary, and lumbar regions are a complete mass of desquamating crusts, cracked and excoriated; the epidermis peeling off in large flakes, leaving the surface underneath red and tender, so that the patient is unable to lie on the back or walk—in fact, the entire of the body is sprinkled over with minute transparent vesicles on a rose-coloured basis, more numerous on the trunk than on the extremities; there is no febrile disturbance; pulse very weak and intermittent; violent pain in head; bowels constipated, and she is so nervous as to be afraid to remain in the dark by herself for any time, crying when alone; the extremities are very cold, and can with difficulty be raised to the normal temperature.

September 15th: Ordered a warm bath.

℞ Pulveris jalapæ compositi grana trīginta.

Submuriatis hydrargyri grana tria. M.

Fiat bolus statim sumendus.

℞ Misturæ purgatis, uncias trōe.

Liquoris antimonii tartarazati, drachmas duas.

Aquæ ad uncias vito. M.

Fiat mistura cujus sumatur cochlearia dua magna bis die.

September 17th: Bowels well cleared; very nervous, and cannot sleep at night.

℞ Liquoris arsenicalis, minumas sexagēta,

Aquæ, uncias vigēta. M.

Capiatur unciam ter die post cibum.

September 21st: Patient is improved; large crusts peeling off the abdominal and lumbar regions; the cutis vera under the crusts is red and moist.

℞ Pilulæ aloes compositi, grana septem in pilulæ duæ, statim sumendus.

24th: Liquor arsenical repeated.

26th: Crusts peeling off in large masses. Linimentum, calcis uncias quatuor; a little to be applied on old linen, and placed on the parts where desquamation has taken place; cannot lie on the back yet; feels much better in every way.

29th: Desquamation still goes on; continues taking the arsenic; is so much improved as to be able to get up and walk about the room.

October 2nd: Patient continues improving every day; crusts falling off in large quantities; the back is nearly quite well; the liquor arsenical to be increased from this date to one ounce of the former recipe (of Sept. 17th), four instead of three times a day.

6th: Crusts clearing off rapidly; on the face, the skin underneath is dry and healthy-looking, but that on the

abdomen and back is moist, and not so normal in appearance. The following to be applied to these parts :

R. Olei olivæ, uncias duas.

Liquoris plumbi acetatis, drachmam. Misco.

Fiat linimentum.

From this date the symptoms improved rapidly under the above treatment, the arsenical solution being taken four times a day. The patient improved so quickly as on the 21st October to be able to resume her ordinary occupation, not one of the crusts remaining, and the general health excellent, which, indeed, throughout was not much disturbed, considering the severity of the case.

I think the above case instructive, when we consider the severity of the eruption, the length of time it had lasted, and the highly nervous condition of the patient, no strong local application being used, the disease, so often remarkable for its obstinacy and resistance to the power of medicine, in this case giving way in so short a time to the influence of the arsenical solution. As to the *modus operandi* of this medicine, I hope on a future occasion to offer some remarks, and also on the external application of the tincture of iodine, which, in some forms, has been found useful, and as a *cure* for this eruption has been so highly extolled.

Grosvenor-road, East, May 10th, 1866.

CASE OF RUPTURED VAGINA.

(Read before the Obstetrical Society of Dublin, 12th May, 1866.)

By Dr. J. ISELL.

So much has been written lately on the subject of ruptured uterus and vagina that it will be perhaps trespassing too much on the patience of the members of the Society to bring forward another case of the kind, but as recovery is rare in such cases, and the after-treatment does not seem to be fully established, I trust I may be excused for relating the following one. Some years ago, whilst doing dispensary duty for my friend Dr. Metge in the country, I met with the case:—

A. B., wife of a poor labourer, æt. 35, was taken ill of her eighth child. After some hours of severe labour the pains ceased suddenly, and there was some discharge of blood from the vagina. The women in attendance sent for me. When I arrived I found the woman in a state of great exhaustion, with a small and rapid pulse, tenderness over the abdomen, through the walls of which I could feel distinctly the limbs of a child. I was informed that she had vomited a blackish fluid. On examining per vaginam I found that the head had receded so as not to be felt, and there was some hæmorrhage going on. The nature of the case was evident; it was one of ruptured uterus or vagina, and to deliver her at once was the best thing to be done.

Accordingly, having given her some whisky and water, I proceeded to turn the child. On passing my hand above the brim of the pelvis, I discovered a large rent anteriorly and to the left side, through which my hand had no sooner gone than it became entangled in the intestines, amongst which I made my way cautiously until I arrived at the feet of the child high up in the abdomen, one of which I seized, and delivered her of a stillborn male child as speedily, but as carefully, as I could. The uterus contracted well, and the placenta came away in about ten minutes; there was not much hæmorrhage. I gave her some more whisky and water, with forty drops of trœ opii, and applied a binder with pads firmly over the abdomen.

I left half-grain doses of opium to be given every fourth hour, and ordered perfect quiet to be observed. On visiting this woman two days afterwards, with Dr. Metge, we found that she had gone on well; her pulse had got up, her strength had improved, she had rested well, had passed water, had no motion from the bowels. The treatment we decided on giving her was Pil. hyd. gr. i.,

opii gr. $\frac{1}{4}$, 6tis horis. The dose of opium was small, but we did not consider it safe to leave larger doses in the hands of ignorant country people.

A kind neighbour sent her some chicken broth, and fed her all through her illness. She continued under this treatment for six days. It was then omitted, and a mild purgative draught was given, which acted well; her mouth was slightly affected with the mercury.

This woman recovered perfectly without a bad symptom, and was able to bind at the harvest about two months afterwards.

I wrote some months ago to Dr. Metge to recall the case to his memory, and received an answer that he had gone to see the woman, and that she was quite well, but has had no more children. She was the mother of eight children—three living and five stillborn. She was a small delicate woman, without any deformity of the pelvis, but the child (a male) was large, and thus a disproportion was caused between the head and the pelvis. The rupture in this case extended from the vagina into the body of the uterus, and was so large as to allow the escape of the child into the abdomen, and it was a matter of no small difficulty, as well as danger, to pass by the intestines and reach the feet during the operation. In truth, I had some doubts on my mind at the time whether I should be able to succeed in my efforts to deliver her.

As the patient is now alive and well, we may fairly ask to what cause are we to attribute her recovery?

There are two causes, I think—one is, that she was so promptly attended to, having been relieved in less than an hour after the occurrence; and another is, the treatment by opium, to both which may be added the good country air in which she lived.

It is very satisfactory to see so formidable a case recover, and it is encouraging to us not to despair in such cases but to use those remedies which experience has taught us to be the most rational.

I have seen about half a dozen cases of ruptured vagina altogether, but never treated any of them except the one I have described. Death was the result in all the others. In one case a rupture was caused by the ignorant women in attendance pulling with all their might at the arm of a child which presented itself, and when they failed in their efforts to drag the child into the world they desisted, and the woman died. Another case was caused by ergot of rye injudiciously given. In another case the woman was left too long in second stage of labour, with a contracted pelvis and a large ossified fœtal head. She died also.

But my object is not to enumerate the causes of ruptured uterus or vagina, but to show the treatment used, which is corroborative of the testimony already borne to opium as the only medicine on which we can rely in these cases, which have hitherto been looked upon as almost hopeless.

CASE OF PLACENTA PRÆVIA.

Mrs. W —, wife of a policeman, ætat. 30, mother of three children, living in Summer-place in this city, was attacked with hæmorrhage at five weeks before her time; I was sent for at eleven o'clock at night; I found her very weak and low, having lost a great deal of blood; I plugged the vagina with a large sponge, having first ascertained that she had emptied the bladder, gave her an opiate, and left her for the night. Next morning at my visit I found her much improved, she had slept and was stronger; I removed the plug and applied cloths wet with cold water, gave her acid inf. rosæ, with Epsom salts, which acted well on the bowels, and the hæmorrhage ceased for about three weeks.

After this some person incautiously told her that a policeman had been shot; she naturally, apprehensive for her husband's safety, became sick and faint, and hæmorrhage immediately set in.

This attack was not so severe as the last, it was controlled by cold applications and rest, but her strength was

much impaired by the shock and loss of blood. However, she went on by great care and watching to her full time, and her labour came on about a fortnight afterwards; up to this period the os uteri was high up and not at all dilated.

Labour commenced with smart hæmorrhage. I had recourse again to the plug and cold cloths, and watched the case, having made up my mind to rupture the membranes should the hæmorrhage increase. After some hours I removed the plug in order to ascertain how matters were going on.

I found the os uteri still high up, about the size of a sixpence, and rigid, the pains very feeble, and the discharge continuing.

I then passed up along the index finger of the right hand a knitting-needle, which I directed and pushed through the os with the left, and ruptured the membranes. An unusual quantity of liquor amnii came away, at first mixed with blood and afterwards quite clear. The bleeding ceased for about two hours when it returned again more profusely than ever.

The poor woman by this time was much weakened and she lay in a motionless and helpless state, not expecting to survive.

There was but one resource left, which was to deliver her without delay, as every moment was of the most vital importance.

Accordingly I proceeded at once to deliver her by version, having first given her some whisky and water. On reaching the os I found it not larger than a shilling, and still rigid. By first getting in one finger, then a second, and finally forming my hand into a cone, I succeeded in getting it into the uterus. I soon reached the feet, one of which I grasped, turned the child, and delivered her of a fine boy alive, which I did not expect after so much loss of blood on the part of the mother.

The placenta came away in a quarter of an hour, but there was no disposition on the part of the uterus to contract, and for three hours I had most assiduously to keep pressure with the hand and cold on the uterus before I could ensure its contraction and check the hæmorrhage which was going on.

I gave her all this time stimulants with *træ opii*.

On examining the placenta I observed a portion of about the size of a five-shilling piece, flaccid, dark looking, and covered on one side with adherent clots of blood.

This woman recovered well but slowly, being very weak and suffering from headache; she had also prolapsus ani, for which she was treated by Dr. Nolan. Her infant died about a fortnight afterwards of convulsions (as I was informed), for I was not consulted about it.

There are two circumstances in this case which I think are worthy of notice, one is, that after the membranes were ruptured and the waters discharged, although the hæmorrhage ceased for a time, yet it returned again with greater violence than before, without any uterine action whatever. Another is, that I did not wait until the os was dilated, but in a manner forced my hand through, for had I waited even for some minutes she would have either bled to death or have been reduced so low as to render any attempt at delivery most hazardous.

I saw a case some years ago in which hæmorrhage was induced by a lady having received a letter one morning announcing the death of a friend. She fell down in a faint and lost at the moment a large quantity of blood. She was put to bed, given restoratives, and recovered somewhat after a time, but the bleeding continued for a week. At this time I was called in to see her; I found the bleeding going on; the os uteri only the size of a shilling, with the placenta implanted over it; the pulse scarcely to be felt; her face blanched, and in fact dying, and in half an hour she breathed her last.

If the practice of gradually dilating the os uteri at an early period which I made use of in my case had been adopted with this lady, I am morally certain that her life would have been saved.

A CASE OF ATAXIC LOCOMOTIVE PROGRESSIVE PARALYSIS.

By R. MURNEY, M.D.,

FELLOW AND LICENTIATE THE COLLEGE OF SURGEONS, IRELAND.

THE case which I am about to describe will serve to illustrate a disease (if my diagnosis be correct) which is well known in Dublin, but not so well throughout the country, it is for the latter reason that I venture to bring forward this case so as to ventilate the subject as much as possible. I confess that I cannot throw any new light on the pathology of the disease, inasmuch as I had no post-mortem in the case. The disease ran its course in four months, terminating in perfect recovery, which was contrary to my prognosis, as I looked on the symptoms indicating a disease which experience has hitherto, at least, found to be incurable. The disease I allude to is the ataxic locomotive progressive, described by M. Duchenne. The subject of this paper is a young gentleman of about 20 years of age, tall and well proportioned, fair complexion; he consulted me on the evening of the 7th of last February; said he suffered great pain since four o'clock in consequence of not being able to pass any urine, made some about eight o'clock in the morning, but none since, though having made many efforts; said this incessantly came on without any cause that he was aware of; was in his usual health and spirits the previous day, and slept well the night before. I passed a catheter without the least trouble, urine natural in quantity and quality, and acid reaction, sp. gr. 10.20, it was microscopically examined by Dr. Barker, who pronounced it healthy. I passed the catheter twice each day for fifteen days. At this date the bladder recovered itself for a short time. On the third day of my attendance on him his gait became unsteady, and when turning round staggered. In the course of a month, as those symptoms increased and became aggravated, could not walk with his eyes shut, had great difficulty in maintaining his balance, when once in motion he could get on pretty well by moving quick with his head down and eyes fixed on the ground. About a week after the bladder recovered itself another and distressing condition of it set in, incontinence of urine; his face presented a peculiar sardonic grin, apparently drawn to right side; no anæsthesia on the left; right eye amaurotic; pupil dilated; appetite bad; lived on wine and brandy occasionally. His friends were greatly afflicted at the appearance of his face, being so much changed; did not perceive it himself; his memory was not as perfect as usual; he became careless and filthy in his habits; complained of pains in his thighs and legs. The history he gave of himself was:—Had always enjoyed good health; both his parents and all his family were living; a few days before last Christmas got for the first time in his life pain in his head and back, with sick stomach; went to bed; lay for three weeks with a feverish cold, as he was told by the medical man who attended him when convalescent; went to Kingstown; there became strong in a short time; a few days before his return to town got a pain in the lower part of his back corresponding to the fourth lumbar vertebræ; it was very severe for some days; the intensity of it gradually lessened and finally disappeared. When first consulted the treatment consisted of citrate of quinine and iron, a blister over the region of the bladder, beef-tea, wine, &c., subsequently tinct. of ergot, strychnia, nitrate of silver; the latter medicine he continued to take for four weeks without ever making any change in the colour of his skin. The patient himself imagined he was very much improved, though I could not perceive it. Went to Galway on the 2nd of April to see some friends there; returned on the 4th of May to Dublin, to my great astonishment strong and fat, and to all appearance quite recovered. How long he will continue so remains to be seen. While in Galway discontinued the nitrate of silver pills and all other medicine. On my first interview with him after his

return, the first thing he did was to walk with his eyes shut and dance a polka. I confess that on this occasion I was not a little shaken in the correctness of my diagnosis, but when I grouped all the symptoms—the staggering gait, the peculiarity of raising and putting down the foot, the heel first, the head bent, with eyes looking down on the ground, the amaurotic eye, and the inability to walk with eyes shut, which M. Trousseau says is pathognomonic of the disease ataxic—all these symptoms confirmed me in my former diagnosis. The only other disease that this could be confounded with is reflex paralysis. On this subject I published two papers, in one of them the disease was ushered in by loss of power of the bladder, succeeded by incontinence of urine. In those two somewhat similar, but totally different diseases, you have in both the staggering gait, the peculiar motion. In the ataxic the heel is first put down, in the other (reflex) the toes. In the latter the patient can walk with his eyes shut and his head erect, never any affection of the eyes or face, which we know is not the case in the ataxic.

In those cases of reflex paralysis alluded to, both recovered, they were read and discussed at the meetings of the Surgical Society of Ireland.

Hospital Reports.

WESTMINSTER HOSPITAL.

TWO CASES OF EXCISION OF THE TONGUE BY THE EMPLOYMENT OF THE ÉCRASEUR.

Under the care of Mr. BARNARD HOLT,
SENIOR SURGEON TO THE HOSPITAL.

In a late number of the *Medical Times and Gazette* Mr. Paget has recorded two cases in which he excised the tongue for epithelial cancer, by first dividing the genio hyo-glossi muscles with the knife, and subsequently removing the tongue with the écraseur. The two following cases are recorded to prove that there is no necessity to divide these muscles with the scalpel at all, but that the operation may be entirely completed with the écraseur, and usually without the loss of any blood that becomes either a source of annoyance to the surgeon or danger to the patient.

W. G., æt. 72, a moderately healthy man, stated that fourteen years since he noticed a small hard lump at the tip and side of the tongue; it gradually increased in size, and for the last two or three years he experienced great pain, of a stabbing, lancinating character, and an increase of saliva that materially interfered with deglutition, the combination of the two resulting in attenuation to a marked degree. Upon admission a hard nodulated growth was detected, which implicated more than the anterior half of the tongue, but the submaxillary glands were fortunately not involved. Mr. Holt decided to remove the tongue with the écraseur. On March 5th, the patient being thoroughly under the influence of chloroform, Mr. Holt first passed a strong silken ligature through the anterior portion of the tongue, so that it might be drawn by an assistant as far forwards as possible. A strong curved needle fixed in a wooden handle, which had been previously threaded with a ligature attached to one side of the chain, was next passed under the tongue as far back as possible, and the chain was drawn through the opening thus made; the chain was now fixed to the écraseur, and the whole of the parts beneath the tongue were slowly and cautiously divided. The tongue, being now set free, could be drawn out of the mouth by traction on the first ligature to an extent sufficient to allow the chain of the écraseur to be passed in the form of a loop over the tongue to its root, when, by the action of the handle, the loop was tightened and the tongue slowly severed from

its attachments. There was hardly any bleeding, indeed not sufficient to call for the application of ice or the perchloride of iron, which was in readiness. In the afternoon the patient was quite comfortable, and could swallow beef-tea without difficulty. He progressed in the most satisfactory manner, day by day improving, taking his food naturally, the only inconvenience being his inability to disengage small fragments of meat from the teeth, and by the 5th of April was perfectly recovered. He could talk sufficiently well to make himself easily understood by any of the patients in the ward.

Case 2.—G. B., æt. 57, a shoemaker by trade, was admitted into the Westminster Hospital, under Mr. Holt's care, suffering from epitheliomæ of the right half of the tongue. The disease, unlike that of the previous patient had only existed for two years, and was attributed to the irritation caused by smoking a clay pipe. It had latterly increased in size and density, and there was just previous to the operation a very slight hardness of the glands beneath the jaw. As, however, this had only been noticed for a few days, Mr. Holt did not consider it a bar to the operation. While under the influence of chloroform Mr. Holt commenced the operation in the manner already described, and after cutting through the floor removed the whole tongue from its base. The hæmorrhage from the left lingual artery was sufficiently active to require its inclusion in a ligature. The artery on the right side, or that on which the disease was situated, did not bleed. The patient was placed in bed and shortly had some tea, which he drank without difficulty, and on the second day from the operation was walking about the ward.

Mr. Holt remarked, that the foregoing cases clearly showed that the tongue might be removed entirely by an operation through the mouth without either dividing the jaw or making any opening in the integument beneath the chin. The chain of the écraseur can, with the greatest ease, be passed far back beneath the tongue so as to divide the genio hyo-glossi muscles and the mucous attachments which so far releases it as to enable the operator to pass the loop of the chain over the tongue to its base, and so insure the entire removal of the organ.

In the first case there was the merest oozing of blood, in the second there was a jet from the left lingual artery, but Mr. Holt believed this might be avoided by standing in front of the patient instead of at the side, and this position, in reference to the patient, is attended with two advantages—first, that the lingual arteries would be more evenly compressed and only be pressed through at the last moment; and secondly, the loop of the écraseur could, with greater certainty, be pushed around the root of the tongue, the straight part of the instrument where the surgeon stands in front being passed into the mouth—a proceeding that cannot be effected if he stands at the side of his patient. So far as the operation was concerned, nothing could be easier or more effectual. The results have yet to be judged of.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS.

DR. LYONS'S CLINIQUE.

Double Pneumonia; Tonic Treatment; Recovery.—A brief notice of the following case may be worthy of record: The patient, a boy, aged 16, an inmate of a blind asylum, was admitted into hospital labouring under acute pneumonia, which was found to engage the entire posterior half of both lungs. Consolidation existed in the lower portions, and in the scapular and supra-scapular regions evidence of rapidly advancing inflammation of both organs was furnished by extensive crepitus. On the following day both lungs were found to present absolute dulness on percussion posteriorly from apex to base. The pulse was 112, respiration 60, and thermometer 100 1-5th°.

The patient was at once placed on five-grain doses of

sulphate of quinine, given at three-hour intervals, with beef-tea and six ounces of wine, and after the seventh day an egg. The quinine was well borne, and was continued at the above doses for several days. On the second day after admission smart pain in the right side was complained of, and the patient was cupped to the extent of three or four ounces with marked relief. It may be observed that from beginning to end of this case this was the sole measure of a lowering or depressing character employed, and it is worthy of note that almost from the period of admission the patient's appetite was remarkably good, he eat abundantly of bread and milk, and constantly craved for more food. Slight diarrhoea presented itself on the third day after admission, but was easily controlled. Pyrexial action continued pretty high for many days, as evinced by the pulse, respiration, and thermometer. On the third day after admission the pulse fell to 100; on the fifth day it was 96, the respirations 40, while the thermometer registered but $98\frac{1}{2}^{\circ}$. Slight renewal of pyrexia took place some days subsequently, and on the seventh day after admission, the twelfth of the disease, the pulse was 116. In the four or five subsequent days the pulse went gradually down to 96, to rise again in the three following days to 120. Henceforth it fell daily until it reached 84, and so continued, convalescence being now fairly established, the lungs well cleared up, admitting air freely throughout, and giving clear resonance on percussion. It may be a question, in reviewing the history of this case, how far the persistence of appetite for food was dependent on the absence of that irritant and depressing influence ordinarily exercised in such cases by tartar emetic or mercury.

Cerebro-Spinal Arachnitis; Exudation of Lymph on Cord.

—J. B., aged 16, assistant in a provision dealer's establishment, was admitted into hospital on 6th April. The circumstances of his illness were the following:—Several days prior to admission he came into Dublin from Wicklow on an outside car. He got a severe wetting on the journey, wore his wet clothes after his arrival, and did not change or dry them after he got home. He wore the same damp clothes on the two following days. On the third day after the wetting he felt pains in his bones and down along the spine. These pains grew more severe daily, and he was at length obliged to seek admission into hospital.

When seen on the day after admission, his condition and appearance were peculiar. The decubitus was diagonal, and his head was drawn forcibly backwards, the retraction appearing to be due to action of the deeper muscles, and not at this period to those superficially observable, as the trapezii and sterno-cleido-mastoid. Any attempt to get the head into the natural position was painful to the patient, and immediately abandoned when he was with difficulty induced to make the effort. No decided complaint was made of pain except low down in the back, and when it was attempted to get him into the sitting posture. He then expressed himself as suffering considerable pain through the back, and felt an inability to sit upright. He was enabled, by aid of an attendant and by resting on one arm, to maintain himself in a semi-erect position, and half inclined to one side for a short period, but begged to be allowed to lie down; and as the object was only to test what lesions of muscular power existed, this examination was made only at rare intervals and for brief periods. His condition might be said to be rather that of an apprehension of great pain and distress, and of a sense of incapacity to sit up or bend the head forward, than of actual suffering in the effort, or absolute want of muscular power to perform it. Symptoms of pyrexial excitement had been present at the period of his admission, but when first seen by Dr. Lyons his pulse was only 72, and there was no observable calor. He took food and drink readily, and the principal functions were at this time performed naturally. On the fourth day after admission the pulse had risen to 120, and for a fortnight subsequently ranged about 104: on a later occasion

it jumped from 108 to 140, but fell next day to 120. His condition continued little changed during this period. Subsequently he began to wander, occasionally fastened on a word, such as "Oh, father!" "Oh, father!" which he repeated over and over again. On other occasions he would repeat continuously some word which struck him in a question put to him. He was occasionally very despondent about himself, at other intervals he said he was "stout." A very slight amendment in the power of nodding the head was observable for a few days, but he soon relapsed; and the same may be said of his power of attempting to sit up in bed. For about two days there was hyperæsthesia of the feet and legs, but this symptom disappeared. Later on in the disease, urine and fæces were involuntarily discharged, but even in this condition there was temporary amendment. For the first three weeks he took food with appetite and drank copiously of milk, he also readily took wine, beef-tea, and other nourishment allowed him. When about a fortnight in hospital a very slightly paralytic state of the left side of the face was noticed, and subsequently he became partially hemiplegic at the same side, but there was a decided amendment in this condition previous to death. In the last fortnight of his illness he wasted much, and he died after a sojourn of about thirty-five days in hospital. On the day prior to his death, complete relaxation of all the contracted muscles took place, and he lay on his side with his head in its natural position, the face highly flushed; he was partly unconscious to what took place around him, but was not comatose.

In the progress of this case almost every conceivable remedial agency was put in operation, but absolutely with no sensible effect on the disease. He was leeches, cupped, and blistered on the head and spine. Persistent efforts were made to bring him under the influence of mercury by internal administration of calomel and mercurial inunction, but without the smallest effect on his gums or any proof of constitutional effect. Iodide of potassium was administered for a protracted period with no observable result. Belladonna was applied to the spine externally and administered internally until slight but well-defined physiological effects were induced, as shown by dilatation of the pupils, but no benefit ensued to the spinal lesion. Finally, the patient was carefully fed throughout, and when evidence of any failure of power was manifested he got six ounces of wine daily. He took nourishment at all times readily, but sank, worn out in the end by the continuous wear and tear of his disease.

Post-mortem Examination.—The cranial sinuses were charged with blood; minute dotted particles of lymph exudation were here and there noticeable on the arachnoid, and there was some slight serous effusion in the circle of Willis. On slitting up the membranes of the cord the arachnoid was found coated with lymph for a space of about three inches corresponding to the junction of the cervical and dorsal portions, and low down on the cauda equina there was a very copious effusion of serum, with particles of lymph here and there.

Dr. Lyons remarked on the fatal character of this disease as familiar to all observers, and on the unusually protracted duration of the case in question. In the majority of instances on record the disease was, however, an acute and fatal one. In this case the whole duration of the disease exceeded forty days. Its very rebellious character, and the failure of all medicinal agents hitherto employed, are further deserving of note.

MATER MISERICORDIÆ HOSPITAL.

REMARKABLE CASE OF SOFTENING OF THE LEFT ANTERIOR LOBE OF THE CEREBRUM, WITH RIGHT HEMIPLEGIA, AND LOSS OF SPEECH.

(Under the care of Dr. HAYDEN.)

JANE QUIN, aged 47, the mother of one child, and gene-

rally healthy, with the exception of a few attacks of rheumatism, was admitted on the 17th of March, 1866.

It appears that on the night of the 27th of December, 1865, she went to bed well, and next morning it was found that she had lost the use of the right side of the body, including the face, and also the power of speech.

On examination it was found that there was total loss of voluntary motion in the right arm, and partial loss of it in the right leg, which she dragged in walking, and was barely able to draw up or to extend when in bed. Not so, however, with sensibility, which was complete both in the leg and in the arm. The features were drawn to the left side, and the tongue, when protruded, deviated to the right. The patient could, however, close both eyes, wrinkle the forehead, and move the tongue to either side when told to do so. She could swallow well; her intelligence was perfect, but she seemed to have lost recollection of words, or rather of the mode of enunciating them. There was no difference in the size of the pupils; the pulse, counted by the heart, numbered 160, and was very weak; the action of the heart itself was most irregular; both sounds were morbidly clear, unattended with murmur, and extensively transmitted over the chest. There was not any paralysis of the sphincters, but the patient was constantly moaning. On the 21st of March it was noted that about eight p.m. on the previous day the clinical assistant, Mr. McKenna, had remarked the patient complaining of pain in the head, when, placing his hand on her forehead, he ascertained that the temperature on the right side of the face was morbidly high and attended with throbbing, while on the left, or unaffected side, the surface of the face was perfectly cold and entirely free from throbbing. The right side of the face was also found to be tender to the touch. She took pills of mercury with chalk and James's powder—one thrice daily—and an expectorating mixture.

On the 23rd it was noted that she had then been pulseless for the last two days; that livid patches were to be seen on the back of the right hand, as well as on the fingers and toes; that there was constant and most distressing moaning, with involuntary evacuation of the rectum and bladder.

On the morning of the 24th neither the action of the heart nor the radial pulse could be heard or felt; the constant and painful moaning continued; there was livid coldness of the extremities; the patient seemed to be conscious, and could swallow fluids; there was slight œdema of the right side of the face and of the upper (right) eyelid, which, in consequence, she could not fully raise. At four p.m., having for some hours before ceased to moan or make any attempt at speaking, she died. There had not been any appearance of convulsions. A post-mortem examination was made at the expiration of twenty-four hours, when it was noted that the brain was of normal consistence and apparently healthy, with the exception of the anterior lobe of the left hemisphere, which was much reduced in volume, of a light yellow colour, and semi-diffluent. The convolutions and sulci in the inferior surface of this lobe were obliterated; the left olfactory nerve and bulb were softened and enlarged, and the former had become cylindrical and raised out of the corresponding sulcus by obliteration of the latter. There was not any extravasation of blood or effusion of lymph, and no embolus was found in any of the bloodvessels of the brain. In the heart the left auricle was enlarged and thickened; the left auriculo-ventricular orifice was much contracted (see measurements below) by cohesion of the segments of the mitral valve.

The thickness of the left auricle, at its upper and left portion, was one-quarter of an inch; at its middle and left portion it amounted to one-eighth of an inch. The thickness of the left ventricle, at its central portion, was one-half of an inch; at its apex it was one-quarter of an inch. The mitral orifice barely admitted the tip of Dr. Hayden's index finger.

After some days immersion in spirit, the cineritious substance of the left anterior lobe was ascertained to be

of the consistence of cream, and was, on microscopic examination, found to consist of fat globules of various sizes; of large granule cells; of compound granular corpuscles; of many crystals, needles of margarine, and of a few crystals of hæmatine. The white substance from the same situation was composed of the same elements, with the addition of beaded nerve-fibres and a few plates of cholesterine.

On making a horizontal section of both hemispheres of the cerebrum, about the anterior three-fourths of the corpus striatum was found entirely broken down, of the consistence of cream, and to have altogether lost its identity in the surface of section. The extra-ventricular nucleus had disappeared, but a small portion of the intra-ventricular nucleus, about the size of a pea, remained in the small extremity of the corpus striatum, and in the neighbourhood of this the brain substance was firm. The optic thalamus was unaltered, as likewise was the entire motor tract on the right side. The second and third left frontal convolutions were disorganized and obliterated, as also were the orbital convolutions. There was not any extravasated blood in the brain substance, nor was there evidence of apoplectic effusion at any former period. There was no embolus in the left middle cerebral artery, nor the least appearance indicating such to have existed at any former period.

The impairment of the faculty of articulate language was very remarkable in this case. The patient's intelligence was unaffected, and her mind seemed full of ideas and of the proper words to express them. She made repeated attempts to express in words to Dr. Hayden her wants and sufferings, which she effectually expressed by signs, but she could not succeed in bringing out a single word beyond the monosyllables "yes" and "no." On one occasion, in answer to a question having reference to her illness, she said—"Six-oo." The full answer would have been "six weeks." On another occasion she was asked her name, which was Jane; she attempted to reply, but could not. A list of names was then called over; she said in reply to each, "No," and after a little she became excited at one failure (which was not intentional) to discover her name, and at her own inability to assist us, she became flushed in the face and apparently angry, and said emphatically, "No, no, no." At last the right name was pronounced, when she seemed pleased, and at once said, "Yes, yes, yes." On another occasion she suffered pain in the abdomen and wished to direct Dr. Hayden's attention to the part. He affected not to comprehend her signs and unintelligible utterances. She lost temper and attempted to sit up in order to point out the seat of pain to him. At that time she was incapable of writing, from paralysis of the right hand, but Dr. Hayden was convinced that she had not lost the memory of words, else she would not have incessantly endeavoured to give utterance to them. If the memory had failed, the mind, not the tongue, would have been employed to supply the deficiency.

Nor, in Dr. Hayden's opinion, was the loss of the power of articulating due to paralysis of the organs of speech, for the patient was capable of protruding her tongue and moving it to either side, although it deviated to the right when she tried to protrude it directly forward; she grasped the drinking vessel firmly with her lips, and deglutition was perfect.

It seemed, therefore, to Dr. Hayden that the defect consisted in loss of the power of motor coördination of the organs of speech, by which their movements are so ordered and combined that articulate language is the result.

Without subscribing to the full extent the ingenious theory of Dr. Moxon, published in the last April number of the *British and Foreign Medico-Chirurgical Review*, Dr. Hayden agrees with that gentleman in thinking there is sufficient reason to conclude that the situation of the ideas of *associated motions* which form the faculty of speech is supra-motory, whilst the situation of the ideas of *associated sensations* which form the faculty of language-com-

pression is supra-sensory. If it be true, as Dr. Moxon further surmises, that the seat of the acquisition of language, and indeed of all the other intellectual acquisitions, is a symmetrical, or restricted to one side of the cerebrum, then we can have no difficulty in understanding how it is that a local lesion, involving only a very limited portion of one of the cerebral hemispheres, may obliterate the acquisition of language, by destroying, as it were, the tablet upon which it had been engraven. It is easy to understand why the seat of language should be in continuity with the motor tract; for spoken language consists in vocal sounds, modulated or "articulated" by the voluntary muscular action of the organs of speech. Hence the necessity for direct continuity between the seat of the acquisition and the motor tract, through which alone it may be manifested. For the same reason aphasia is, in the vast majority of cases, associated with some degree of hemiplegia.

Dr. Hayden has not been able to satisfy himself as to the precise cause of the cerebral ramollissement in this case. The suddenness of the attack and the previous existence of valvular disease of the heart would lead to the suspicion of embolism of the left middle cerebral artery as being the cause at once of the hemiplegia and of the aphasia, or rather of the disorganization of cerebral tissue, which gave rise to these symptoms. The most careful examination however, failed to discover embolus in this vessel, or in any of its branches.

The absence of a murmur preceding the first sound of the heart, with *mitral contraction*, was another feature of much interest. According to Dr. Hayden's experience, this form of valvular lesion is always expressed by a pre-systolic murmur, audible at the apex, and a little above, save during the period of extreme debility shortly preceding death, when, owing to the diminished force with which the chambers of the heart propel their contents, it is as invariably suspended.

In the case just detailed the patient, it is true, was under observation for nine days, during which the murmur was inaudible; but it should be remembered that throughout this period her state of muscular weakness was extreme, and her pulse was with difficulty detected by the touch.

Another lesion which Dr. Hayden has invariably found after death in this form of valvular disease, and which existed in this case, is pulmonary apoplexy.

ST. VINCENT'S HOSPITAL.

CASE OF FRACTURE OF THE NECK OF THE FEMUR—DEATH ON THE FOURTH DAY BY FATTY HEART.

(Under the care of Dr. MAPOTHER.)

[Reported by Mr. E. NUGENT.]

MARY BRIEN, aged 74, a charwoman, was admitted at three o'clock on May 1st, on the recommendation of Dr. Byrne, for fracture of the neck of the left femur, which had occurred four days before from a fall on that side. It was arranged that Dr. Mapother was to see her at five o'clock, and, in the meantime, the limb was supported with pillows by the clinical assistant. The left leg was everted but not shortened, and she was unable to lift it from the bed. She complained of no pain, conversed with the patients around her, and after awhile expressed a desire to sleep. In about an hour the ward-maid went to her bed for the purpose of offering her some food and found her dead.

On examination of the body next morning, Dr. Mapother found that the left ventricle had a deposit of fat of, at least, an inch in thickness, and that the muscular wall within this was extremely thin. This he considered had caused her death. There was a considerable ecchymosis over the left trochanter, and some very slight effusion of blood outside the front of the capsular ligament, but none within it; the edge of the head of the femur, which had been projected downwards upon the neck, was

crushed off for about two inches of its circumference anteriorly and superiorly, and the head seemed to be forced with great obliquity backwards.

On section, it was found that a fracture traversed the neck in an angular manner with the projection downwards, and that the lower fragment had been forced up for half an inch into the head of the bone. The osseous tissue was thoroughly infiltrated with fat. The right clavicle had been broken thirty years ago by the efforts of wringing a quilt, and it presented after death a most admirable example of false joint. The fracture was at the junction of outer with the middle third of the bone, each of the ends of the fragments were rounded, somewhat flattened, and covered with a smooth hard substance resembling half-calcified cartilage.

They were joined by a loose capsular ligament which allowed their separation for at least three-fourths of an inch, and lined by a synovial membrane. The corresponding shoulder-joint exhibited the characters of chronic rheumatism in a marked degree.

The specimens have been all preserved admirably by Dr. John Barker in the Museum of the Royal College of Surgeons in Ireland.

CASE OF ERYSIPELAS OF HEAD, NECK, CHEST, AND ABDOMEN.

ROSE STYNES, aged 37, wardmaid in the Rotunda Lying-in Hospital, was seized with erysipelas on the 1st of May, five days after puerperal fever had broken out in that institution. When admitted on the 3rd, there was great redness and serous swelling of the face and head, but there was neither coma nor delirium. The tongue had a slightly brown fur, and the pulse was 94; there were no other symptoms worthy of comment. An aperient dose of calomel and jalap, carbonate of ammonia and bark mixture in effervescence, beef extract, and six ounces of wine were prescribed. She was placed in a separate ward, the windows and door of which were kept almost constantly open, but the body of the patient was kept warmly clothed. Dr. Mapother adopted free ventilation, as being both curative of the disease and preventive of its extension to other patients. In the next few days the erysipelas travelled gradually downwards, especially along the lines of the lymphatic vessels and glands, and at last passed the umbilicus; the skin, in the places it had passed, having desquamated.

The constitutional symptoms having shown some signs of failing, the amount of wine was increased to fourteen ounces in the twenty-four hours at the suggestion of Dr. O'Ferrall, who watched the case throughout with interest, and every effort was made to supply nutriment by means of egg mixture and beef extract. On the 12th she became semi-comatose; the extremities showed signs of failing circulation and loud râles were to be heard in the chest. The case continued to fluctuate between life and death until the morning of the 15th inst., when she sank gradually by asthenia.

ERGOT OF THE "DISS." (LALLEMONT.)

Ampelodesmos tenax, link, or the Arab "diss," a plant found in Algeria, yields a fungus which possesses all the properties of ergot of rye. It is from one-ninth to one-third of an inch long, and from one-sixth to one-eighth of an inch thick, and of a blackish or chestnut-black colour. It is found to keep very well. The following analysis has been made by M. Lallemont—

Fatty oil and crystalline fat	30.6
Ergotine (Wiggers)	2.3
Vegetable albumen	3.6
Sugar, gum, and nitrogenous matter	7.0
Fungin	50.2
Salts of lime and silica	6.2

Experiments were made during the course of a year with the preparations of *diss* ergot, and the trials were crowned with complete success. The dose employed is one-half less than that of ergot of rye.—*Year-Book of Pharmacy.*

Proceedings of Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 24TH.

Dr. ALDERSON, F.R.S., President.

ON A CASE OF HYDATID DISEASE OF THE LIVER, AND REMARKS ON THE TREATMENT OF SIMILAR TUMOURS.

By JOHN HARLEY, M.D.Lond., F.R.S.,

ASSISTANT-PHYSICIAN TO KING'S COLLEGE HOSPITAL, ETC.

MR. B. G —, aged 29, the subject of an enormous hydatid tumour of the liver, had been under the author's care for more than two years before final proceedings were taken for his relief. In June, 1863, the lower part of the chest and abdomen were greatly distended by a dull, elastic, fluctuating tumour; the lungs and heart were displaced upwards, and the rounder lower border of the tumour could be felt two fingers' breadth above the pubes and Poupart's ligament. The centre of the swelling was at the epigastrium; the hypochondria were enormously distended, and the lower parts of the chest-wall were widely spread outwards. The patient was much deformed by the swelling, and he measured forty inches and a half around the body midway between the ensiform cartilage and the umbilicus, where the tumour was most prominent. During the next two years this measurement gradually increased to forty-two inches and five-eighths, and the tumour descended a little from the chest. On the 17th July, 1865, the patient was seized with a severe pain in the right iliac region. On the 26th the measurement round the body at the line above indicated was forty-four inches and a half, and, fearing rupture, the author resolved to puncture the tumour, and next day Mr. Bright of Forest-hill introduced a medium-seized trocar at a point in the median line midway between the ensiform cartilage and the umbilicus. On withdrawal of the trocar clear fluid like water was ejected with great force, and nineteen and a half pints, containing many minute hydatid cysts, were removed. The last two pints were of a bright yellow colour from admixture with bile. The whole tumour appeared to be in an actively growing condition, and a little of the turbid fluid presented, when examined, vesicles about one-thirtieth of an inch in diameter, with from five to nine scoliers attached to them; very numerous free scoliers, some with retracted, others with everted hooklets; and hundreds of detached hooklets.

The patient was greatly relieved by the operation. The subsequent treatment consisted in maintaining permanent communication between the interior of the sac and the surface of the body. The canula was retained for the first forty days, and its place was then supplied by an elastic catheter, and the passage was gradually dilated by the introduction of others until three No. 12 elastic catheters could be introduced within the sac. The catheters were constantly retained six or nine inches within the sac. A free discharge of bilious fluid (about twenty ounces daily) and a few fragments of hydatid membrane continued, with occasional slight obstruction, up to Sept. 16th, and the patient progressed without a single bad symptom. On the 16th severe febrile symptoms with slight jaundice arose from retention of the discharge. The evacuation of a large quantity of foetid fluid caused great amelioration, but on the 17th considerable hæmorrhage from the liver occurred, and the sac became distended with blood. Grumous blood and cyst-wall continued to be discharged, and oozing of blood into the sac continued for some days. On Sept. 28th, and again on Oct. 11th, large thick fragments of dense, blood-stained fibrous tissue—evidently portions of the sac which had been connected with the liver—came away. After the hæmorrhage had been controlled the discharge consisted of diluted bile, and after

the sac was washed out, half an ounce of pure,ropy bile could for many days be collected as it flowed from the catheter in the course of a few minutes. About this time the discharge averaged sixteen ounces daily. On Oct. 11th, after the opening had been dilated so as to admit three No. 12 elastic catheters, the whole of the remaining cyst-wall, which had caused continued obstruction to the discharge, was evacuated in the form of yellowish-green laminated membranes of various thicknesses. Henceforward there was no difficulty in completely washing out the sac. For the first four months the alvine secretions were almost continuously destitute of bile, and they were occasionally very offensive. On the 25th of November the discharge had decreased to three ounces, and the cyst was contracted into the right hypochondrium and epigastrium. On the 12th of December the last trace of bile disappeared from the now purulent discharge, and the catheter was finally removed on the 22nd, when the cyst was completely contracted and obliterated. The patient resumed his usual occupation on the 1st of January, 1866, and a few days afterwards the fistulous opening was cicatrized. The patient has improved in health up to the present time. The spleen remains a little enlarged, but the lungs have recovered from their compression, and the heart is restored to its normal position. Throughout the treatment the abdomen continued flaccid and free from pain. Now the liver dulness is normal, and only a thickened cord-like mass can be felt in the epigastrium. The patient is a little stouter than he was before the operation, and the measurement around the same part of the body is now thirty-one inches and a half, which is thirteen inches less than the measurement on the day of the puncture, and nine inches less than when the patient first came under the author's notice in June, 1863.

The main difficulty in the treatment consisted in the evacuation of the membranes of the ruptured hydatids. The utmost attention and perseverance were required to overcome the impediments to the discharge which these membranes continued to offer so long as any portion of them remained within the sac.

While endeavouring to secure free discharge of the fluid formed within the sac, the author had two other objects in view—viz., (1) to prevent decomposition of the fluid within the sac; and (2) to excite inflammatory action in its interior. These were attained by the injection of iodine and creasote water; one drachm of the compound tincture of the iodine of the London Pharmacopœia was injected into the cyst three days after it was punctured. This was continued morning and evening for about a week, when the amount was increased to two drachms twice a day. From the 14th to the 23rd of August one ounce of the tincture was injected daily, and the evening injection was then discontinued on account of profuse night-sweats which the injection of so much iodine appeared to produce, and six drachms were injected every morning only until the 17th September, when it was discontinued altogether. During these seven weeks upwards of thirty ounces of the tincture of iodine, diluted with an equal quantity of creasote water, were thrown into the sac. No pain was ever produced, but when the sac became a little tender a feeling of warmth in the epigastrium followed the injection. When hæmorrhage took place from five to ten grains of nitrate of silver dissolved in a few ounces of water were daily injected for a week, the sac being previously washed out with creasote water. Afterwards the sac was washed out every morning and evening with a solution of sulphate of zinc in creasote water (one drachm to ten ounces).

Throughout the treatment the lower part of the chest was supported by a broad laced bandage, and the abdomen was also tightly bandaged, a compress being placed upon the right side so as to press the contracting sac towards the right hypochondrium.

For a considerable portion of the time during which the patient was under treatment, bile was either altogether absent from the intestine, or it was deficient in quantity. To supply its place twenty grains of inspissated ox-gall

were given in the form of a bolus every night at intervals. So long as the discharge continued free the appetite was good, and the bowels acted regularly; and during the greater part of the time the patient took a mixture composed of perchloride or permearate of iron and quinine.

Having observed this complicated case with much interest, and given it close attention, and subsequently studied the histories of those recorded cases in which cure has been attempted by operative proceedings, the author is convinced of the necessity of observing the following rules in the treatment of hydatid tumours of the liver:—

1. They should be punctured *above* the umbilicus, because the sac, however large, possessing great elasticity, ultimately contracts into the epigastric or hypochondriac regions.

2. As soon as operative measures are determined upon, the sac should at once be punctured with a large trocar, and the canula retained.

3. The canula should be retained until it is loosened by suppurative action and tends to slip out. Its place should then be supplied by two or three elastic catheters, and their size gradually increased until three or four of No. 12 size can be readily introduced. A single catheter or a single very wide silver tube is ineffectual for emptying the sac of its fluid and membranous contents, as the latter form most complete valves for closing the orifice of a single instrument. By using three or more catheters, and advancing the ends of two beyond the others, and causing their eyes to look inwards towards each other, the pliable cyst-wall does not so completely envelop the ends of the instruments, and the fluid runs away through the interstices.

4. To facilitate disintegration of the cyst-wall, and to excite inflammation and adhesion of the sac, iodine should be freely injected until after some time it produces a sensation of a glow of heat within the sac. Then its use should be discontinued.

5. To prevent decomposition of the fluid within the sac, creosote water (thirty minims to thirty-six ounces) should be freely injected morning and evening. Injected down one catheter, it is allowed to flow away by the others, and thus the sac may be thoroughly washed out.

6. After all the cyst-wall has been discharged, the sac should be washed out in the same manner morning and evening with a solution of sulphate of zinc in creosote water (two drachms of sulphate of zinc to thirty-six ounces of creosote water). If this or other astringent solution be used before the expulsion of the disintegrated hydatid membranes, they may become hardened by the solution, and their expulsion thus retarded.

7. The previously distended parts must be constantly kept tightly bandaged. It must be remembered that the adhesions of a large hydatid tumour are very extensive, and that if the parts distended by its growth be not brought and retained together, the contraction of the sac will be retarded, if not in some cases prevented.

The paper was accompanied by a synoptical table of 79 recorded cases of hydatid tumour of the liver treated by various operative measures, or resulting in rupture through the abdominal walls. From an analysis of these cases the author has endeavoured to show that obstruction to the discharge of reaccumulated fluid within the sac, and its retention and decomposition, are the chief causes of death in the fatal cases, and he strongly advocates the formation and maintenance of a free communication between the interior of the sac and the surface of the body.

The tumour in the case above described was of unusual size, and apparently the largest that has been successfully treated, and yet, apart from the hepatic hæmorrhage and diversion of the biliary discharge, no bad symptom ever resulted from opening it, so long as the contents of the sac were freely evacuated. Since, therefore, so large a tumour can be radically cured by the treatment above detailed, much less danger is to be apprehended when the same treatment is applied to smaller ones.

Dr. COBBOLD considered that so remarkable a case as the one just described ought not to be passed over without some discussion. Undoubtedly, there was no case on record where so large an hydatid tumour had called forth similar operative procedures. Whilst Dr. Harley was to be congratulated on the successful issue of the case, he (Dr. Cobbold) was of opinion that the measures adopted in this case were not necessary in the more common forms of hydatid tumour of the liver. The case was quite exceptional. Nature often effected a cure by herself. It was seldom advisable to make such large openings. Dr. Harley, in the course of the paper, had alluded to the circumstance of the patient having been accustomed to eat underdone meat. This habit could have nothing whatever to do with the formation of the hydatid in question. The true explanation of the source of the parasite was very different. The patient probably obtained the larva when he drank (stagnant) water obtained from a locality to which dogs had access. In fact, the prevalence or otherwise of hydatids in any country bears an almost strict relation to the number of dogs permitted to go at large. It explains the great number of echinococcus cases in Iceland, where dogs are, on other grounds, so essential to the peasant. In Denmark the disease seemed more abundant than in our own country. Dr. McGillivray had recently published twenty cases occurring at the Bendigo Hospital. Probably the disease was rather frequent throughout the Australian colonies. It was a very difficult matter to arrive at any correct estimate as to the actual prevalence of hydatids in this country. Dr. Murchison has told us that "out of 2100 post-mortem examinations recorded at the Middlesex Hospital between April 19th, 1853, and August 25th, 1865, hydatids were found in only 13, or once in 161 cases; and in only 7 of the 13 cases, or once in 300 instances, could they be said to have occasioned the fatal event." The expression "only" conveys the notion that the number of cases and deaths is small. In Dr. Cobbold's opinion, however, it is rather large. If such an estimate could be accepted as a criterion of the prevalence of this disease throughout the civilized world, it would give us upwards of 100,000 deaths annually from hydatid disease alone. To those who had not gone thoroughly into the subject, such an estimate might appear extremely absurd; yet, independently of the special hospital data afforded by Dr. Murchison, he (Dr. Cobbold) had, from other considerations, honestly arrived at the conclusion that the above figures were not very much above the mark. In conclusion, to show the many dangers which Dr. Harley's patient had escaped, Dr. Cobbold related the case of a schoolboy who died from the effects of a blow on the right side. The blow was slight, given during play, yet in a very short space of time the boy ceased to exist. The tumour in this lad's case was comparatively small.

Mr. HUTCHINSON felt much indebted to the author of the paper for the careful narrative of a very interesting case, and for the valuable tables he had collated. He could not, however, wholly agree with the rules laid down for the treatment of these tumours. He preferred an early puncture and closure of the orifice to the plan of delaying an operation to the last moment, and then endeavouring to establish a fistula and to remove the cysts. The latter plan was, he thought, productive of needless risk to the patient in more than one direction. If the tumour had developed to the size described in the author's case, then he admitted that the treatment adopted was the best; but the question he wished to raise was, whether the tumour ought to have been allowed to increase to such dimensions. He next related the particulars of three cases in which he had adopted the plan by puncture with a very fine trocar, and closure of the wound. In the first, the patient was a woman, under the care of Dr. James Jones, in the Metropolitan Free Hospital, and the tumour of large size, filling the right side of the abdomen. A washhand-basinful of clear hydatid fluid was drawn off through a very small canula. Some inflammation of the cyst followed, and air

was secreted into it, but in the course of a fortnight the air had disappeared and the cyst was contracting. The patient recovered perfectly, the tumour wholly disappearing. When seen some months afterwards the woman was in good health. The second case was that of a patient seen in consultation with Dr. Hughlings Jackson and Mr. Marsh of St. John-street. This woman was extremely ill, and suffered from constant vomiting. She had a large tumour filling the epigastrium, and bulging below the umbilicus. The diagnosis of an hydatid cyst having been formed, after some persuasion she consented to a puncture, but not until her state had become very critical. About two pints of clear fluid were drawn off. She made an uninterrupted recovery, her symptoms having been at once relieved by the operation. Two months later she was in excellent health, and had no fulness whatever at the site of the tumour. The third case was that of a woman in the London Hospital, under the care of Dr. Parker. The hydatid cyst occupied the epigastrium, and bulged prominently. It had been diagnosed as such both by Dr. Parker and Dr. Hughlings Jackson before he (Mr. Hutchinson) saw the patient. With a very fine trocar, from one to two pints of clear fluid containing echinococci were drawn off. The cyst refilled during the next fortnight, but never became painful. Afterwards it again diminished, and at the present date—six months after the puncture—the patient is in excellent health, and there is no fulness whatever to be discovered in connexion with the liver. In all these three cases the simple evacuation of the fluid sufficed to destroy the vitality of the parasites, and was followed by the shrinking up of the cyst. In none of them were any of the secondary cysts removed. Mr. Hutchinson stated that he used an exploring trocar of the size of No. 1 catheter, and allowed as much fluid to escape as would freely do so, but was careful not to make any rough pressure. In withdrawing the canula he always did so quickly, and with the orifice closed by a finger, so as to prevent the risk of any fluid escaping into the peritoneum. He did not feel to care much whether adhesions existed or not. In two of his cases it was certain that they did not. Mr. Hutchinson added that he thought the estimate of one death in 300 as due to hydatids was too high an estimate as regards English practice. He had seen a few cases of death from these tumours, quite sufficient to show in a strong light the importance of surgical treatment; but still they were very rare. In common with all who make post-mortems, he had met with many instances of collapsed—spontaneously-cured—hydatids in the bodies of those who had died of other diseases. In one case under his own care he had, he believed, witnessed the spontaneous cure of a very large hydatid tumour. The patient was a young Irishman, and the tumour, which almost filled his abdomen, certainly contained from one to two gallons. The operation was repeatedly urged upon him, but he refused to consent. At length he was laid up with an attack of severe pain, which led to apprehensions that the cyst would burst; still he refused to have it punctured. After this the cyst diminished to half its former size, and subsequently the man returned to his work, and Mr. Hutchinson had been assured by the man's sister that the tumour eventually disappeared. He had not, however, had an opportunity of verifying this statement himself. He concluded his remarks by relating the particulars of a case still under his observation, in which a girl of five years old had become the subject of an hydatid tumour in the liver. He had watched this patient for two years, during which the parasite had slowly increased. It appeared still, however, to have a thickness of liver-tissue in front of it, and he had deferred the puncture. The great question as to the puncture of these tumours was when it should be done? Since a large number undergo spontaneous cure, the surgeon ought not hastily to interfere; still, however, he (Mr. Hutchinson) felt confident that an early operation by the method he had recommended was far preferable to the plan of waiting until the patient's life became endangered.

Dr. A. P. STEWART regretted that Dr. Greenhow and Dr. Murchison were not present to speak on cases of hydatid disease which had been under their care in the Middlesex Hospital. Dr. Stewart then alluded to cases of hydatid of the liver in which there had been a great diminution in the size of the tumour; and referred to a striking case in illustration. In the instance he related the patient afterwards died of peritonitis, after exposure to cold. A large hydatid cyst was found in the liver at the autopsy. Dr. Stewart then referred to the case of a patient who had been sent in for operation by Dr. Murchison; but in this instance there was a consultation, and the patient, being afraid of the suggested application of caustics, left the hospital the same day. She afterwards went to another hospital; but soon left it also, and afterwards died at home. There had been, Dr. Stewart said, four cases of operation for hydatid tumour of the liver, and in each case the patient did well after the operation. Dr. Stewart referred to another case now under his care, in which there had been bulging of the chest-wall. When this bulging had subsided, the abdomen increased in size, and he intended in this instance to encourage the operation. There did not seem, Dr. Stewart said, to be any material risk in the operation.

Dr. HARE had listened with great attention to the paper and to the observations on it. He alluded expressly to the observation on the diminution or disappearance of such swellings. In the instance of a patient under his (Dr. Hare's) care, who had two hydatid tumours, one of them disappeared, and the other decreased in size. In this case he had hesitated to operate, because he had not watched the patient long enough, and because the liver-tissue over the cyst was too thick. Dr. Hare then remarked that hydatid tumours of the liver were often multiple. It was, he said, very important to know whether we have to deal with one or more. In some cases, when the tumours are of good size, we may determine the question. Dr. Hare here entered into the points by consideration of which a diagnosis might be made, and related a case in which he had declined to recommend an operation, on the ground that there was more than one cyst. At the autopsy three cysts were found, one of them being enormous. Dr. Hare then spoke of the occasional existence of peritonitis. This he thought ought not to be interfered with by treatment, as the existence of adhesions rendered the operation of tapping more easy.

Dr. HARLEY, in answer to the foregoing remarks, stated that the operation of simple puncture advocated by Mr. Hutchinson and Dr. Stewart, and so successfully practised by the former, was fully considered in the analysis of the synoptical tables appended to the paper. It appeared therefrom that radical cure had been effected in several cases by this mode of treatment, but that it was unsuccessful when applied to tumours of greater capacity than one or two pints. Reaccumulation of fluid was a common result of tapping under any circumstances, and might in any case cause sufficient distension of the cyst to rupture it; and since capillary puncture did not appear to be a safer mode of proceeding than any other, to say nothing of the ulterior object of effecting a radical cure, he preferred in any case retaining command over the fluid in the sac by inserting a full-sized trocar, and preserving an open passage. Dr. Harley would not at so late an hour detain the meeting by further observations, but would, in conclusion, direct the attention of the Fellows to the morbid preparations (hydatid cyst-wall, fibrous sloughs, biliary discharge, and specimens of the echinococci) upon the table, and informed them that the subject of the paper was present among them, and was quite willing to submit himself to examination if any one wished it.

THE yearly average death-rate per thousand is lower in Margate than in any of the great towns of the three Kingdoms: and in Ramsgate the proportion is even comparatively lower.

ACADEMY OF SCIENCES OF PARIS.

APRIL 9.

M. CLOQUET presented a communication by M. CHAMPOUILLON ON

CHRONIC HYPERTROPHY OF THE TONSILS, ITS INFLUENCE ON THE DEVELOPMENT AND HEALTH OF CHILDREN.

This disease is capable, according to its extent, of producing either simple discomfort or even severe suffering. It may completely hinder the development of the soundest constitutions. When the tonsils have acquired a considerable size they press forward, render the *velum palati* immovable, so that the isthmus facium is habitually deformed. They close more or less completely the orifice of the posterior nares and encroach sometimes on the median line so as to transform the guttural orifice into a simple fissure. These changes in the anatomical relations alter the character of the voice and cause extreme difficulty in the movements of deglutition; during sleep respiration is accompanied by râles, the mouth is dry and the breath fœtid.

The Eustachian tube participates almost always in the chronic irritation, its mucous membrane becoming turgid, often occasions deafness. The deformity and contraction of the guttural orifice of the pulmonary passages is of great importance, the immediate result being a proportional diminution in the quantity of air inspired, so that the vesicular murmur is only fully heard at the summit of the lungs. This reduction in the area of respiration is not absolutely incompatible with life, but it is undoubted that insufficient respiration renders imperfect the oxydation of the blood globules, favours anæmia, reduces animal heat, and hinders the elaboration of nutritive material. In course of time the chronic hypertrophy produces a deformity of the thorax described by Dupuytren in 1828.

M. Champouillon considers that in decided cases there is no resource but excision of the glands which, in spite of its numerous difficulties, should never be delayed, for according as we temporize with the malady the restoration of the constitution becomes more difficult. The moment the tonsils have been removed, the lung expands, and everything is changed in respect of the vitality of the organism.

MEDICAL SOCIETY OF THE COLLEGE OF PHYSICIANS, IRELAND.

EIGHTH MEETING—SESSION, 1865-66.

DR. AQUILLA SMITH in the Chair.

DR. HENRY KENNEDY read a paper on

MIXED TYPES IN FEVER.

A number of cases were detailed in which the types of fever, known as typhus and typhoid, were believed by the writer to have co-existed at the same time in the same patient. He also detailed cases where, with a petechial rash, ulceration of Peyer's glands was found after death. Cases were also given in which rose-coloured pustular spots, and in small numbers, were present, and yet no other symptoms of the enteric lesion.

This paper, which led to a very animated discussion, occupying the entire evening, we hope to publish shortly.

The following gentlemen took part in the discussion:—Drs. Burke, Law, Moore, Lyons, Belcher, Darby, Croly, Duncan, and the Chairman.

The next meeting will be held on Wednesday the 30th. Tea at eight. Chair to be taken at 8:30 p.m.

UNITED STATES ARMY.—“Diarrhœa was the army disease. During the warm season, when troops were lying in camps, after long marches or exhaustive campaigns, if one inspected the sinks of the troops, a good, sound, healthy, solid, or even semi-solid stool was a *rara avis*, and one could form an estimate of the prevalence of diarrhœa without looking at the sick reports.”

Reviews.

A SYSTEM OF INSTRUCTION IN QUANTITATIVE CHEMICAL ANALYSIS. By REMIGIUS FRESenius. Edited by LLOYD BULLOCK and A. VACHER. London: John Churchill and Sons.

FRESenius' "Analysis" is so familiar to the scientific world that it would be a work of supererogation to review the intrinsic merits of the book at this stage of its existence. The line drawn out for us, therefore, is more to notice the alterations and additions to the present edition than to give a critical analysis.

But we must be excused if we dwell for a little upon an objection that has been raised to this work on more than one occasion—viz., to the complexity of the arrangement and consequent confusion entailed thereby. Perhaps for ease of reference the repetition of the "Groups" through sundry sections and sub-divisions is objectionable; but upon a clear insight into the plan of the work, what might at first sight appear confusing will afterwards be found conducive to perspicuity and method. It is true that use is second nature, and this may account for our partiality for Fresenius; but we now practically perceive that the arrangement adopted by the author militated against it. It was our fate to use it as a text-book to our studies, and it has remained the work of our choice.

Fresenius' "Analyses," both Quantitative and Qualitative, have taken their stand in England and on the Continent as the works on analytical chemistry, and this, after all, is the best criterion of their general merit.

The fourth English edition of the "Quantitative Analyses" corresponds with the fifth German one. It is edited by Mr. Lloyd Bullock, whose name has been honourably associated with Fresenius from the commencement of its appearance in its English garb. It will be seen from the heading that he has called in the assistance of another chemist. The cause of this will be well understood when we see the size to which the volume has grown since the appearance of its predecessor.

A great many new processes have been introduced; but it is principally in the special part that the extension of the book is evidenced. The analyses of waters and mineral waters is dwelt upon at some length, and new illustrations of some ingenious apparatuses for collecting water containing gaseous products are inserted. Some of the new processes given are not so valuable, in our opinion, as their position in this work would intimate. Thus, in the estimation of tannin, the post of honour is given to a process based upon the following theory, that tannin in the presence of a considerable amount of a solution of sulphindylate of potash is oxidized with it by permanganic acid or chlorine. "You may be sure," says Fresenius, "that the last particle of tannin is oxidized with the last trace of indigo." Now this may work beautifully with comparatively pure tannin solutions; but when we are working with extractive matters from bark or vegetable extracts (which is generally the case in commercial examinations), how can we depend upon the absence of all ingredients which would interfere with this reaction. It is not only probable, but almost certain, that there would be some body present equally, if not more, oxidizable than tannic acid itself; is so, these substances would vitiate the results. For a technical analysis we should prefer Hammer's method, and for accuracy Risler Bennat's, both of which are given in Fresenius. We are still of opinion that an accurate process for the determination of tannic acid has to be discovered.

At page 282 Fresenius gives a special method for effecting the separation of phosphoric acid from iron, which seems very simple.

We think it is an oversight of some considerable importance that no system is given for the examination of urines. Even the estimation of urea is passed over in silence. We are sure that it is an oversight, and that the omission was not from an idea of the unimportance of this subject. We would also suggest that alcoholimetry (a most valuable branch of quantitative analysis) should find its place in this work. We wish this edition of the book the same success which so deservedly attended its predecessors. C.R.C.T.

WATTS' DICTIONARY OF CHEMISTRY. Parts xxxiii. and xxxiv. London: Longman, Green, and Co.

THE May part of this elaborate work brings us down to pyruvic acid, and completes the fourth volume. It commences with the detection and estimation of phosphorus. The determination of the presence of free phosphorus (often a difficult phase of medico-legal analysis) is dwelt upon at some length. Then come the hypophosphites, phosphorous acid, and the phosphites; phosphoric acid, and its triple modifications, also the phosphates—all most valuable and important products of chemistry. A considerable space is taken up by the interesting, but at present not so well known, organic phosphorus bases.

Under the head of "Photography" will be found some practical hints, which will, no doubt, be of use to the professional photographer. The theory appertaining to formation of sun pictures had already been discussed under the head of "Light."

The history, chemistry, and technical applications of platinum form an important monograph, which extends over some twenty pages. The insertion of "Physostigmine" (the alkaloid from Calabar bean, *Physostigma venenosum*) is indicative of the care and assiduity with which Mr. Watts pursues his task. This alkaloid has been investigated since the commencement of the present edition of the Dictionary.

The following articles are the most important ones in these two numbers:—Iodide of Potassium, by the Editors; on the Manufacture of Potassium Salts, by Thomas Richardson; the Potato, Chemical Printing, Propione and Propionic Acid, from the pen of Prof. Wanklyn; Purpurates, and Pyroxylin (gun cotton). "SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 23, 1866.

THE MEETING OF THE MEDICAL COUNCIL.

If any member of the Profession expected that the present Session of the Medical Council was likely to be characterized by any features of peculiar interest or novelty, he will in all probability be disappointed; and although the Council has only just commenced its sittings, we believe we shall not be far wrong in expressing our fears that no amended Medical Bill will be passed in the present Session of Parliament, and we doubt whether even the new Pharmacopœia will make its appearance for some time.

Like the Queen's speech at the opening of a new Session, the inaugural address, for the season, of Dr. BURROWS, the President of the Medical Council, was remarkably destitute of information; but this inanity arose, not as is the case at St. Stephens, from a wish to conceal the real intentions of the Executive, but because

Dr. BURROWS had very little to communicate. He briefly reviewed the proceedings of the last Session, and the progress of events since that period, alluded to the labours of the Committees on General Education and Preliminary Examination, congratulated the meeting on the recent steps taken for the visitation of examinations at the various licensing bodies, and apologised for the delay in the appearance of the Pharmacopœia. He then came to the important subject of the Amended Medical Bills, and stated that he had been engaged since December last in urging their claims to attention upon the Government, which, through the medium of Sir GEORGE GREY, has at last, though as it would seem, rather reluctantly, consented to their introduction into Parliament. It is already known that the Counsel to the Home Office has been for some time engaged in framing a draft Bill in reference to the Medical Profession, but in consequence of numerous matters pressing upon the Government at the commencement of the Session, it had not made much progress. But Dr. BURROWS assured the meeting that the HOME SECRETARY had embodied in his bill all the clauses comprised in the measure prepared by the General Medical Council, and just before the assembly of that body on Thursday last the draft memorandum was forwarded to the President, who had also received two notes from Sir GEORGE GREY upon the same subject.

This glimpse of ministerial action towards the profession excited, as might be expected, an eager desire to know something more than the President had yet communicated, and a general wish was expressed that the important letters from Sir GEORGE GREY should be read. Hereupon arose a discussion whether, as one of the letters was marked "private," the contents ought to be made generally known, or whether it would not be more expedient to refer the documents in the first instance to a committee with directions to draw up a report; and one or two of the members of the Council moved that the representatives of the press should withdraw, lest, we presume, the oracular utterances of Sir GEORGE GREY should be prematurely divulged, but this motion was not pressed. It turned out, however, that the precaution was unnecessary, for the first of Sir GEORGE GREY's notes, marked "private," merely expressed his general approval of the Bill, and his regret that he had no time to introduce it at present, owing to other more pressing Parliamentary engagements, and the second note contained very little more than an intimation that the word "private" was written on the first note by mistake.

Such, then, was the mountain in labour, and such the ridiculous mouse brought forth, and we may remark that although the House of Commons cannot yet afford time to entertain a Bill providing for the legalized Medical attendance on human beings, it has found time to discuss one in reference to the Medical attendance of horses!

Still we apprehend that the Medical Profession in general will consider all the other operations and discussions of the Medical Council quite insignificant in

comparison with the great object of amending the present Medical Act, which, for almost all purposes for which it was said to be designed, is utterly worthless. It gives no protection to the Profession, and it gives no security to the public; the first being defrauded of his lawful emoluments by a nest of quacks and the second (the public) being unable to distinguish between the true man and the counterfeit. The dissatisfaction of the Profession in reference to the Medical Act has gone on increasing ever since the passing of the measure, and its utter worthlessness is now more than ever manifested, until at last the dissolution of the Council itself would be regarded with the most perfect apathy unless it can bring about some amendment in the existing law. We believe that the members of the Council themselves adopt this view, and we give credit to Dr. BURROWS for his praiseworthy exertions in pressing the matter upon the consideration of the HOME SECRETARY. It is the duty of the Profession itself to agitate in every possible manner for an amendment of the present Act, and to demand that the Medical practitioner, who has been regularly and expensively educated, should at least be allowed the same protection which is accorded to the members of the Church and the Law.

As we are going to press, the Draft Amended Bill has come into our hands, and we publish it elsewhere. Its provisions will be very satisfactory to the Profession, whose support it deserves; and we hope that our misgivings as to its passing the Legislature this Session will be falsified.

MEDICAL MEN AND THEIR PATIENTS.

At the present time when there is a wide-spread movement going on amongst all classes of this country for an amelioration of their condition, when artisans and mechanics are demanding large advances on their wages, and when there is a universal outcry for short work-hours and half holidays, we think it is not out of place to inquire whether nothing can be done to lessen the tear and wear imposed upon the hard-wrought members of the medical profession. Can the public who applaud and encourage every effort that is made to lighten the labour and improve the position of the labouring classes to whom this nation undoubtedly owes much of her prosperity and wealth, do nothing to ease the burden which most of the junior and many of the senior members of our calling have to bear? It is considered a noble thing to elevate the lower classes in all that relates to social comfort and domestic happiness, to wipe the sweat from the brow of honest toil, and to provide for the working man not only the time but the means for recreation and amusement. Is it less noble to strive by more prudent arrangement and more thoughtful consideration, to save the doctor time and trouble, to procure for him some little leisure from the cares and anxieties with which his daily path is so thickly beset? There is no class of working men whose labour is more incessant, whose duties are

more responsible, whose holidays are fewer, whose hours of retirement and recreation are so liable to be broken in upon than that which is composed of medical practitioners. Their very meal hours are not free from interruption, and if an attempt is occasionally made to snatch from professional engagements a brief interval for social or domestic enjoyments, how frequently is the attempt a failure, how seldom is the anticipated pleasure realised! Nor is the harassing nature of their avocations often made the subject of grumbling or complaint.

Cheerfully they endure and untiringly labour on, sustained by the consoling thought that no labour can be more blessed than that which is expended in the alleviation of human suffering and the mitigation of pain and anguish. It is only when, through the thoughtless inconsiderateness of the public, much annoyance and trouble, which might easily have been avoided, is caused, when much valuable time is lost which a more judicious arrangement might have saved, it is only in such circumstances that the voice of complaint is raised. While ever willing and ready to respond to an urgent call, the members of our profession naturally feel it a hardship to be expected to attend to demands upon their time which are trifling and unfair. We would, therefore, appeal to our patients to rectify such abuses, for it is in their power and in theirs alone to provide a remedy for the grievances we allude to. If they would only bear in mind that most medical men are in the habit of arranging every morning the round of calls they intend to make during the day, so as to enable them to get through their work with as much convenience and despatch as possible, people would surely endeavour, wherever it was practicable, to leave their messages at an early hour, instead of putting off till later in the day. Such an arrangement would be better for the patient and better for the practitioner too, for while the former would be more speedily attended to, the latter would be spared the unnecessary trouble of retracing his steps to a district where he had already been, and this after being exhausted by the day's work.

Another tantalizing occurrence in the daily work of a medical man, one which happens more frequently in country than in town practice, is to be summoned late in the day to see a patient who resides at a distance, and who, though ill, it may be, for days, only sends then because it suits his convenience. Of course the convenience of the doctor is never for a moment considered by such people, and although he may have just a short time previously returned from a long weary round of visits, he is expected to answer the call immediately; and very likely when he sees the patient he finds that some such serious operation as the incising of a gum-boil, or the extraction of tooth, is all that is required.

There is still another annoyance to which practitioners are exposed, and which we are anxious to direct attention to, because it is one which affects not only the comfort of the medical man himself but of the community at large. We allude to the practice which is still too com-

mon of disturbing the peace of any public assembly by calling out the doctor who happens to be one of the audience. We have frequently seen the evils of this in church, in public meetings, and at musical entertainments, and often the beauty of some eloquent speech or the harmony of some exquisite piece of music has been entirely marred by the confusion caused by a sudden call for the doctor. Now there are comparatively few cases so urgent as to require the medical man to leave a meeting in the middle of a speech, or during the performance of a musical composition. This is an evil which medical men we think might help to remedy themselves, however, for by leaving proper instructions at home, or by staying away altogether from public places when urgent cases were expected, they might save themselves and others much inconvenience. Notwithstanding what we have here said, we are nevertheless quite aware that sources of annoyance must of necessity frequently arise which no foresight or arrangement can prevent. But, on the other hand, we are anxious that the public should know that they have it in their power to relieve the members of the Medical Profession from much unnecessary trouble in the performance of their onerous duties, and we are certain that we will not make the appeal in vain; for when it is known that a little more thoughtfulness and a little more careful management are all that is required to bring a great amount of comfort to the class of men who spend their lives in ministering to the wants of their fellows, we are persuaded that the request we here prefer will not be denied.

NURSES' TRAINING INSTITUTION FOR DUBLIN.

A SHORT time since we had occasion to advocate the establishment of Anglican Sisterhoods, or Nurses' Training Institutions in Ireland; and, in doing so, we took the opportunity of placing before our readers some definite information as to the establishment and working of institutions of the kind in England. At the same time we stated that an establishment for this purpose was contemplated, and would, in all probability, be shortly established in or near Dublin. We need not here repeat our arguments, or give any particulars as to what is proposed to be done in this matter, because a prospectus, which speaks for itself, has been issued, and we need only furnish our readers with the following extract from it:—

"NURSES' TRAINING INSTITUTION.—It is well known that much difficulty is found in obtaining nurses properly qualified to attend on patients in hospitals and in private families, especially those of the middle classes, and of the poor. The only remedy for this evil seems to be to raise up a better class of nurses, who will undertake their work with a high sense of duty.

"It is therefore proposed to establish, on a very small scale, a training institution for nurses, similar to those which have been found so successful in London, Liverpool, Southampton, and in many other parts of England, as well as on the Continent. The Board of Steevens' Hospital have already kindly given permission to allow suitable women to be sent there for some hours daily, under a

trained superintendent, to learn their duties. It is therefore hoped to arrange matters for the object desired without much delay.

"It is intended to provide a small house or lodgings near this hospital, capable of accommodating the Lady-Superintendent and eight nurses.

"Each nurse will receive from £12 to £14 per annum, according to age, fitness, &c. The expense of each nurse cannot be reckoned at less than £37 per annum; and, with other expenses, the cost of the institution will, it is calculated, amount to nearly £450 the first year.

"It is hoped that that after the home has been established for a year or two, part of its maintenance will be defrayed by the payment to the institution for nurses sent to the rich; but as the nurses are also intended for the poor, and for others who would be unable to defray much of the necessary cost of a nurse to the home, it must and will depend mainly on subscriptions from those who approve of the proposed plan.

"The Lady-Superintendent, as well as those employed as nurses, will be strictly forbidden to interfere in any way with religious teaching in the hospital, their duty being simply to nurse the sick with attention and tenderness.

"Many of the leading physicians and surgeons in Dublin are of opinion that an institution of this kind is desirable.

"The home will be conducted on the principles of the Church of England and Ireland, and will be visited by a clergyman.

"*Patron.*—His Grace the Archbishop of Dublin.

"*Committee.*—The Hon. Mrs. R. C. Trench, Mrs. W. C. Plunket, Harcourt-street; Mrs. Huband, Herbert-street; Miss M. Trench, Trimleston; Mrs. Staveley, 13, Adelaide-road; Mrs. Tyner, Steevens' Hospital.

"*Visiting Clergymen.*—Rev. Perceval Graves, and probably the Rector (or Curate) for the Parish.

"*Treasurers.*—Judge Berwick, 5, Upper Merriion-street; Robert Law, Esq., M.D., Upper Merriion-street.

"Contributions will be thankfully received by the Treasurers and by the Hon. Mrs. Trench, Palace, Dublin."

We need scarcely say that as the true mission of medicine is—in the well-known words of Dr. WATSON—to extend its benefits "to men of every religion, and to men of no religion at all," we heartily wish the proposed institution God-speed, and we shall strenuously, and *ex animo*, advocate its interests, and endeavour to extend its influence and usefulness.

INSTITUTION FOR THE PROTECTION, TRAINING, AND EDUCATION OF THE IDIOTIC AND IMBECILE CHILDREN OF IRELAND.

Two months ago we directed attention to the effort then being made to found an institution under the above title in or near Dublin, and we ventured to predict success for the charitable and humane gentlemen who had identified themselves with the project. We are now happy to be able to state that the wished-for success has, to a considerable extent, attended their efforts; that funds are being daily collected, or subscribed for, to a large amount; and that the idea bids fair to become a fact. To complete this, however, the friends of the undertaking should by no means relax their efforts; nor should they, who are disposed to give, withhold their money under the impression that more is not wanted. Very much more is wanted to place the institution on a permanent and sound basis.

In our former notice we referred to the exertions of

Dr. KIDD, the learned editor of our contemporary, the *Dublin Quarterly Journal*, and we directed the attention of our readers to his able pamphlet on the entire question. This pamphlet is, we understand, out of print; and as many are desirous of reading it, we hope the Committee will request Dr. KIDD to prepare a second edition, which will be the best possible advertisement of their charitable institution.

THE LUNACY ACTS (SCOTLAND) AMENDMENT BILL.
